Photo from IMMUNOCYTOCHEMISTRY

Prentice-Hall's Foundations of Immunology Series

gives expression to the expanding world of contemporary biological science—

Series Editors: Dr. Abraham G. Osler, Public Health Research Institute of the City of New York and New York University School of Medicine, and Dr. Leon Weiss, The Johns Hopkins University School of Medicine

IMMUNOCYTOCHEMISTRY
Ludwig Sternberger, Edgwood Arsenal and The Johns Hopkins University School of Medicine

NEW—the first comprehensive text on immunocytochemistry designed for the biologist and pathologist seeking information on immunologic and immunocytochemical principles, as well as the immunologist interested in problems of cytology and pathology. **IMMUNOCYTOCHEMISTRY** deals with the chemical and immunologic foundations of the various immunocytochemical methods and with the principles and scope of their application. 1974, 256 pages, $11.95

THE IMMUNOBIOLOGY OF TRANSPLANTATION
Rupert Billingham and Willys Silvers, both at the University of Pennsylvania School of Medicine

In this concise text, the authors provide a comprehensive account of the basic principles and general concepts of the immunobiology of transplantation. They discuss the origins, methodology, and distinctive language of the subject, as well as its unsolved problems and future prospects. 1971, 209 pages, paper: $5.50, cloth: $10.50

THE CELLS AND TISSUES OF THE IMMUNE SYSTEM: Structure, Function, Interactions
Leon Weiss

Dr. Weiss' book concisely expresses the major functions of the immune system in terms of the activity and structure of tissues and cells which produce antibodies and carry out other immune functions. 1972, 252 pages, paper: $7.50, cloth: $10.95

Absence of significant chromosome damage in males occupationally exposed to lead—*M. L. O'Riordan and H. J. Evans* 50
Lead over-absorption in a population of oxy-gas burners—*W. Taylor, M. K. B. Molyneux and E. S. Blackadder* 53
Clonal restriction of the immune response to phosphorylcholine—*W. Lee, H. Cosenza and H. Köhler* 55
Lacunae in erythrocyte monolayers induced by adherent leukocytes—*W. B. Shelley* 57
Is the area postrema a control centre of blood pressure?—*P. Ylitalo, H. Karppanen and M. K. Paasonen* 58
Mechanism of the viscoelastic deformation of collagen—*R. E. Cohen, C. J. Hooley and N. G. McCrum* 59
Ion beam etching of red blood cells and latex spheres—*M. Spector, L. C. Burns and S. L. Kimzey* 61
Optically detected conformational changes in haemoglobin single crystals—*M. W. Makinen and W. A. Eaton* 62
Fluoridated hydroxyapatite solubility and caries formation—*E. C. Moreno, M. Kresak and R. T. Zahradnik* 64
Reversal by narcotic antagonist of a narcotic action elicited by a conditional stimulus—*R. Drawbaugh and H. Lal* 65

A New Year –
A New Journal: Cell

January 1st was not only the first day of a new year—but also the publication date of the first issue of **Cell**, a new monthly journal of cell and viral biology from The MIT Press. Edited by Benjamin Lewin, formerly the editor of *Nature New Biology*, **Cell** provides a wide-range journal publishing articles of general interest in molecular biology, cell biology, tumor virology and immunology, genetic development and other related areas. Papers are refereed as rapidly as possible and those accepted will be published within twelve weeks.

Cell also includes an extensive review section. In addition to those reviews with the traditional role of discussing a field in some depth, short reviews give conceptual accounts of recent advances in areas of cellular biology, for the benefit of researchers in other areas. Book reviews and discussions of meetings are also included.

The January issue of Cell includes the following articles:

Genetically directed preferential X-activation seen in mice: U. Drews, S. R. Blecher, D. A. Owen and S. Ohno

Ouabain-resistant mutants of mouse and hamster cells in culture: R. M. Baker, D. M. Brunette, R. Mankovitz, L. H. Thompson, G. F. Whitmore, L. Siminovitch and J. E. Till

A uridine kinase-deficient mutant of 3T3 and a selective method for cells containing the enzyme: L. Medrano and H. Green

SpoT, a new genetic locus involved in the stringent response in E. coli: T. Laffler and J. Gallant

The messenger-like poly-A containing RNA species from the mitochondria of mammals and insects: M. Hirsch, A. Spradling and S. Penman

Existence of methylated messenger RNA in mouse L cells: R. P. Perry and D. E. Kelley

Arrangement of specific oligonucleotides within poly-A terminated Hn RNA molecules: G. R. Molloy, W. R. Jelinek, M. Salditt and J. E. Darnell

Mixed splenocyte cultures and graft versus host reactions selectively induce an "S-tropic" murine type C virus: C. J. Sherr, M. M. Lieber and G. J. Todaro

Studies on the levels of cyclic AMP in cells transformed by wild type and temperature sensitive Kirsten sarcoma virus: R. A. Carchman, G. S. Johnson, I. Pastan and E. M. Scolnick

The February issue of Cell will include the following articles and reviews:

Viral Hepatitis, the B Antigen and Liver Cancer: A. J. Zuckerman

Integration and Excision of Phage Lambda: M. Gottesman

GUG and UUG are Initiation Codons In Vivo: J. H. Miller

The Molecular Biology of Tumour Viruses, edited by John Tooze: B. Mahy

Altered Metabolism of the Guanosine Tetraphosphate, ppGpp, in Mutants of E. coli: G. Stamminger and R. A. Lazzarini

Continuous Production of Radiation Leukemia Virus in C57BL Thymoma Tissue Culture Lines: Purification of the Leukemogenic Virus: M. Haas

Changes in RNA in Relation to Growth of the Fibroblast. I. Amounts of mRNA, rRNA and tRNA in Resting and Growing cells: L. Johnson, H. Abelson, H. Green and S. Penman

Manuscripts and editorial correspondence should be addressed to the Editor or European Editor.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système Internationale. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Survival of common bacteria in liquid culture under carbon dioxide at high temperatures —*K. A. Souza and L. P. Zill* 67
Production of bladder stones by human T mycoplasmas—*A. M. Friedlander and A. L. Braude* 67
Genetic dissection of active electrogenesis in *Paramecium aurelia*—*Y. Satow and C. Kung* 69
Regulation of spawning behaviour in the female goldfish—*N. E. Stacey and N. R. Liley* 71
Evidence for the two-state model of nematode behaviour—*M. R. Samoiloff, S. Balakanich and M. Petrovich* 73
Calcium carbonate in termite mounds—*J. P. Watson* 74

BOOK REVIEWS

Cosmology now (Laurie John, editor)—*J. Gribbin* 75

Recent Scientific and Technical Books v

The appearance of *Nature* in a once-a-week format coincides with severe restrictions on industrial use of power. This number is thus, we regret, reduced to ninety-six pages in length. Arrangements have been made to publish the journal weekly during the period of stringency, but the January 11 issue has had to be cut to sixty-four pages. We hope that *Nature* will grow back to its planned size shortly thereafter. Delays in despatch, other than those introduced by the post, are not expected.

The *Nature* logo on the front cover and elsewhere is basically Baskerville Old Face. This was designed by John Baskerville (1706–75) who introduced several new elements into eighteenth century lettering, although his types were not put to wide commercial use until 1923. The rest of the journal is set in members of the Times family—Bold and Semi-bold for headings and New Roman for the text.

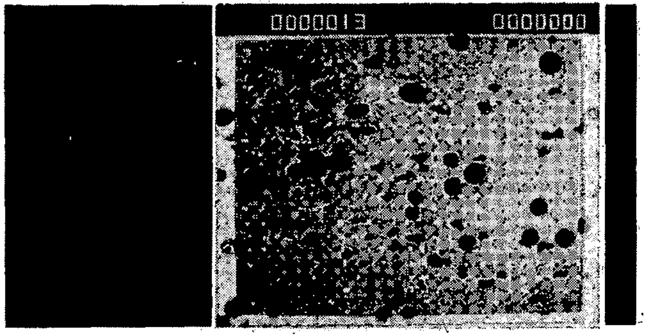
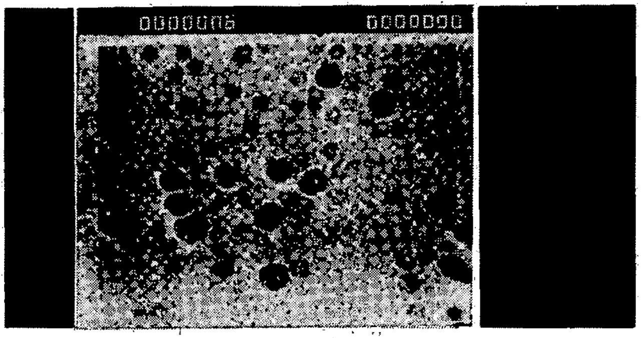
COMPUTERS THAT **SEE...&**



MEASURE WHAT THEY SEE



Quantimet image analysing computers measure anything you can see. They:

★ Look at anything—photographs, microscope images, cine films macro objects . . . .

★ Give exact numbers, sizes, assays, densities, shapes and statistics on everything in view. . . .

★ Recognise selected objects in images and measure them only . . . .

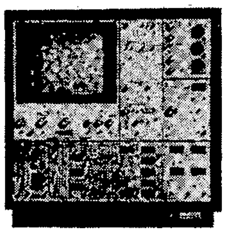
★ Provide this information at speeds up to 1,000 fields of view a minute.

1

2

3

1 The Quantimet measures the total nucleic acid content of the nucleus plus cytoplasm of a single cell.
2 In a sample containing both air and water atomised particles of a sintering steel, the Quantimet separates from the irregular particles (water atomised) and agglomerates, the regular particles (air atomised) and counts and measures these only.
3 The Quantimet counts only the mature neutrophils having rejected the immature forms by applying the nuclear form factor. area/perimeter².



More than 500 Quantimets are saving time & money for their owners in research, quality control & clinical laboratories throughout the world.

Two further volumes in the highly successful Fundamentals of Botany Series edited by W. A. Jensen and L. G. Kavaljian

Evolution and Plants of the Past

Harlan P. Banks

This book is a wide-ranging discussion of a number of important aspects of palaeobotany. The basic approach is an examination of the way in which plants have developed from the earliest times. In contrast with the more traditional approach, in which each group of plants is examined separately, this book looks at each geological period and treats its fossil flora as a whole. As a result a much more dynamic and interesting story is told.

£1.60

Plants, Man and the Ecosystem

Second Edition

W. D. Billings

This elementary introduction to ecology discusses the relationship of plant individuals and populations to their environments and to their roles in the ecosystem. The second edition has been completely reset in an attractive new format, and the text has been revised and expanded so that it now includes a discussion of man and his relations with the plant world.

Government by stealth and secrecy

BRITAIN is now confronted with a severe economic crisis, the ingredients of which are well known, and even when the miners, engine drivers and power station engineers return to full-time working there is bound to be a period of general inconvenience and little prospect of improvements in the standard of living for some time to come. Many things are bound to change as a result of the crisis and it is to be hoped that among them will be the style of government under which Britain has operated for a very long time—specifically the obsessive secrecy and stealth with which Whitehall works and the serious lack of information provided to the public.

This complaint is, of course, fashionable and it is equally fashionable to pay lip-service, as did Mr Heath in 1970, to 'open government'. The question is not whether Britain provides less information than other countries, although it palpably does in comparison with, say, the United States, but whether it provides enough information for those who wish to know, and who do not choose to work for the Civil Service, to be able to come to independent and balanced conclusions.

A conventional defence is to point to such institutions as Question Time in the House of Commons and a free press. This is a very shallow response. The character of Question Time is to find quick, witty and crushing responses to issues raised. This is a political process and success at this facile operation is deemed to be a prerequisite of a good politician. This highly prized skill with words, which spills over into all political exchange, does nothing but damage to a country which needs rational assessment. It is no accident that 'evaluation', a word used almost to excess in the United States, is relatively rare in Britain.

Can a free press make up for this deficiency? Journalists have to depend on a heterogeneous collection of sources for information, from leaks to plain inference. It is simply not possible always to guarantee that one man working against a system will be successful, and it would be foolish to expect more than honest effort. A free press is no replacement for free information and no journalist would regard an increase in the flow of facts as other than beneficial to his operations, certainly not as a threat to his profession.

During the energy crisis the government has operated sufficiently frequently by stealth and suppression of information to raise serious doubts that its style can be supported indefinitely by an electorate. After weeks of denying that the fuel shortage was serious enough to warrant strong corrective action, ration books are issued with such indecent haste that the As and Bs with coughs and colds have probably missed out. After Post Offices close for the weekend nine days before Christmas an announcement is made that no further Christmas parcels will be accepted. After talking of still going for growth, in the full knowledge of fuel shortages, the government days later imposes a three-day working week and demolishes thoughts of growth.

This is rule by edict and secrecy and is not, it must be emphasised, restricted to the present government. Rather, the channels for advance warning, discussion and compromise fail to exist.

There is much talk at present of the appointment of an energy supremo in Britain, and several names have been mentioned. It is difficult to know whether the idea can be welcomed. If the supremo is a party politician dedicated to the present system of operation and only prepared to give political answers to questions, then the creation of another agency may profit the country not at all. If, on the other hand, someone can be found who will work honestly and openly and recognise the need for the public to receive facts and figures in support of decisions he will deserve wide support.

100 years ago

ON TEMPERATURE CYCLES

SINCE the discovery of an eleven years' period in the phenomena of solar spots, several corresponding periods (it is now well known) have been demonstrated in terrestrial phenomena, more especially in those of magnetism, auroras, cyclones, and rainfall. With regard to weather changes, it has been thought by Dove, that the tracking of a cycle in these could not, theoretically, be made an object of research ; and that while some indications of a periodicity might appear, a great part of the complicated changes named must be, from the nature of the case, quite unperiodical. The series of observations by Dove on the subject led him to the conclusion (1) that divergences from the normal, especially those of temperature, are not local, but spread over large surfaces ; but (2) that negative divergences, in one region of the earth, are compensated by positive in another ; and conversely. That the compensation is perfect, and that the quantity of heat annually given by the sun is constant, has been affirmed also by Maury and others.

From Nature, 9, 184, January 8, 1874.

news and views

Global dissemination of hepatitis B virus

INFECTION with the virus, or at least one of the viruses, of hepatitis type B is associated with the appearance in the serum of a specific antigen previously referred to as Australia antigen. Hepatitis B antigen has been found to possess a common group specific surface antigen *a* and at least two principal subdeterminants *d* and *y*, which behave in a mutually exclusive manner although carried on the same antigen particle. Transmission experiments to human volunteers and the common observation of only one subtype in localised outbreaks of hepatitis B infection suggest that the subtypes are the phenotypic expression of distinct genotypes of the virus and are not determined by the host (Le Bouvier, *Am. J. Dis. Child.*, **123**, 420; 1972). Bancroft and his associates (*J. Immunol.*, **109**, 842; 1972) first detected two additional antigenic subdeterminants, named *w* and *r*, and the following phenotypes of hepatitis B virus were recognised: *adw*, *adr* and *ayw*. The missing fourth phenotype *ayr*, which seems to be uncommon, has since been described in the Far East. A remarkable geographical pattern of distribution of hepatitis B antigen subtypes is now emerging (see *Nature new Biol.*, **242**, 34; 1973) with four global zones, where there is an excess of one subtype, and regions where a mixture of subtypes is common.

Diversity of subtypes

Recent studies illustrate this geographical diversity. The high proportion of immigrants in Israel from all over the world provides an almost unique variety of ethnic and geographical background. Approximately half of the blood donors in Israel are foreign-born and most of the others are first-generation Israeli-born Jews. Bar-Shany and her colleagues (*Vox Sang.*, **25**, 105; 1973) characterised 180 asymptomatic antigen-positive blood donors for subdeterminants *d* and *y*: 122 (78%) of 154 males and nine of twelve females carried *y*. Of sixty consecutively identified antigen carriers, selected initially according to their suitability for subtyping and subsequently for representation of dissimilar geographical background, forty-seven (78%) carried the subdeterminant *y* and thirteen (22%) carried *d*. Immigrants to Israel from North Africa, the Near and Middle East, Southern European countries and Southern Russia had almost exclusively subdeterminant *y*, in contrast to the predominance of *d* among blood donors living in North Central and North Europe and North America. Interestingly, Jewish immigrants from South Central Europe have an intermediate frequency of the *d*:*y* pair between North and South European donors.

Twenty-five hepatitis B antigen-positive samples, selected for suitability for subtyping and for geographical representation, were tested for subdeterminants *w* and *r*. All were found to carry *w*, despite variegated geographical origin. It would be reasonable to anticipate that at least some immigrants may have acquired their antigen carrier state after reaching Israel and therefore that the proportion of *y* may differ from carriers still resident in the countries of origin. Such a shift towards *y* might be expected especially in first-generation Israelis from high *d* prevalence areas, provided exposure at school or similar places commonly resulted in spread of hepatitis B virus. First-generation Israelis of Northern or Middle European background, however, had the same frequency of subdeterminant *d* as immigrants from these regions, suggesting the home as the important site of transmission.

These facts are in agreement with the view that close and/or prolonged contact is necessary for transmission by hepatitis B carriers. Feinman and his associates (*Lancet*, ii, 867; 1973) subtyped sixty-three symptom-free blood donors, who were found to carry hepatitis B antigen in Toronto: thirty carried subtype *adw*, eight *adr* and twenty-five *ayw*. When the geographical origin of the donors was investigated, the subtypes were found to be unevenly distributed. Most donors who were *adw* were born in Canada, China, Germany and the West Indies, whereas most of those who were *ayw* originated from Mediterranean countries. All eight donors who were *adr* were born in China. 139 family members of forty-six antigen-positive donors were also tested and eighteen (13%) first-degree relatives of nine index cases were found antigen-positive. Subtyping of the antigen in fourteen relatives showed that all had the same subtype as the index case.

The relationship of subtypes to the country of birth and the home rather than place of residence supports the concept that the carrier state of hepatitis B antigen is determined early in life. But even these studies may be an oversimplification of the problem. Soulier and Courouce-Pauty (*Vox Sang.*, **25**, 212; 1973) recently obtained results from subtyping of hepatitis B antigen, using unabsorbed or selectively absorbed antisera, which suggested the subdivision of antigens with the *ay* subdeterminants into three categories and the *ad* subtypes into two categories. These categories could not be explained in terms of the *w* or *r* subdeterminants since *w* was found in all five categories. The results can be explained, however, by postulating the existence of three subdeterminants of the common group specific determinant *a*, so that *a* is designated *a1*, *a2* and *a3*. Thus *ay* is classified as *a1y* (found in this study in 13% of apparently healthy Vietnamese carriers), *a2y* (found in most healthy French carriers and patients with antigen subtype *ay*) and *a3y* (mostly African carriers of *ay*). On the other hand, *ad* is subdivided into *a2d* (common *ad*) and *a3d* (apparently a very rare subtype).

The differences between the subspecificities of *a* may be both qualitative and quantitative, probably with overlapping and predominance between these three subdeterminants. As with the *d* and *y* subdeterminants *a1*, *a2* and *a3* are related to the virus and not to the host. In this study it was noted, for example, that whereas *a1* was found in Vietnamese, it may also be found in Caucasians after a stay in Vietnam; conversely, some Vietnamese living in France were found to carry *a2*. The same is true for *a2*, which is common in Caucasians (but not restricted to them) and, although *a3* seemed to be most common in African countries, it was also found in French Caucasians who became infected in Africa.

Geographical zones

The overall picture which is therefore emerging is a Y zone, with antigen phenotype *ayw*, incorporating the Middle East, Iran and Pakistan, the Eastern Mediterranean and Southern European countries and Africa (although Africa has not been adequately studied). The D zone, with phenotype *adw*, is centred in North Europe, North and Central America, and both *adw* and *adr* are prevalent in the Far East, Thailand, Malaysia, Indonesia and New Guinea. The R zone, predominantly *adr*, seems to be located in South East Asia and the Far East. The fourth region is the Pleotypic zone, centred in Oceania and particularly around Bougainville, as reported on page 38 of this issue of *Nature* by Mazzur and her colleagues. In this region practically all possible mixtures of the recognised phenotypes of hepatitis B antigen have been found.

Incursions of different subtypes into these zones and the establishment of mixed zones inevitably result from population movements. But since the subtypes are determined by the virus and not by the host, an epidemic of one strain of hepatitis B virus might result in a spate of that particular uniform strain at one time, and a later epidemic of a different subtype might leave carriers of another subtype even in the same area. This has been recorded in Stockholm, for example. Magnius and his associates (*Scand. J. infect. Dis.*, 5, 81; 1973) examined stored sera from seventy-two patients with viral hepatitis admitted to a hospital in Stockholm in 1953–54 and sera from 202 patients with hepatitis admitted in 1970. Hepatitis B antigen was detected in 43% and 49% of the patients respectively. The subtypes from these two groups and from ninety-five antigen-positive drug addicts were determined. Twenty-two (71%) of thirty-one patients from the 1953–54 group were of *ad* subtype whereas only two were *ay* (seven samples could not be typed). In 1970, however, seventy-five (76%) of ninety-nine patients were *ay* whereas only twelve were *ad* (the remaining twelve sera could not be subtyped). Ninety (95%) of the antigen-positive drug addicts were *ay* and five were *ad*. A shift has thus occurred in Stockholm since 1953–54 from predominantly *ad* to the *ay* subtype. It is speculated that the tourist influx from Northern Europe to the Southern Mediterranean countries, the Middle East and North Africa, an *ay* zone, as well as the attraction of these countries to drug addicts may have been factors in the shift of hepatitis B antigen subtypes noted in Stockholm.

The latest report by Mazzur and her associates in the current issue of *Nature* also confirms the varied geographical distribution of antigen subdeterminants *d*, *y* and *w*, and, although the antigen mapping of the world is fragmentary and far from complete, information is rapidly accumulating. Hepatitis B antigen has previously been shown to be a useful epidemiological marker; it may well prove to be a fascinating ecological marker of both ancient and more recent population migration.

Plant diversity in grassland

from our Plant Ecology Correspondent

THE publication by the Kent Trust for Nature Conservation of papers given at a conference on chalk grassland management held a year ago at the King's College Field Centre, Rogate, Hampshire, will reopen the question of what determines plant species diversity in this habitat (see *Nature*, **240**, 443; 1972). It may also raise new questions regarding the objectives of management practices and priorities in conservation.

The diversity issue has been clarified by Grime (*Nature*, **242**, 344; 1973), who has come to the conclusion that diversity in grassland habitats is clearly related to environmental stresses. If stress is low, then grasslands become dominated by species of high physical competitive ability, that is species which grow rapidly, are robust and produce dense litter. Stress reduces the performance of these species, allowing other species to enter the community as a result of the lowering of competition. Diversity thus increases with stress until the stress becomes so severe that only species which are specifically adapted to that particular adverse factor are capable of survival. Then diversity falls. Some authors emphasise the role of predation in the maintenance of vegetation diversity (for example, Harper, *Brookhaven Symp. Biol.*, **22**, 48; 1969) whereas others feel that nutrient availability may be the critical factor (for example, Green, *Biol. Conserv.*, **4**, 378; 1972).

In the recently published report (*Chalk Grassland*, ed. by Jermy and Stott, Kent Trust for Nature Conservation; 1973), both sides of the argument are represented. Wells considers that the composition of a grassland community can best be understood by reference to the respective life forms and growth periods of its constituent species. In other words, if mowing or grazing stresses are applied to a grassland then the species which lose the smallest proportion of their above ground biomass will be at a selective advantage. Tall, robust species are eliminated to the advantage of short-growing species, thus allowing the development of a diverse assemblage of species with an average 67% of low-growing hemicrytophytes.

Harding defends the point of view that nutrient availability limits the growth of aggressive species. Using Shannon's diversity index, he demonstrates a negative correlation between angiosperm diversity in the grass sward and total nitrogen in the soil. He follows Green in the belief that a build-up of nitrogen in the soil permits invasion and attainment of dominance by robust species, thus reducing overall diversity. It is always dangerous, however, to infer causation from correlation. One could equally well argue that the presence of robust, dominant species causes a build-up of nitrogen in the soil by rapid litter production and hence the encouragement of soil microbiol activity, including nitrogen fixation. Suspension of robust species by applying a grazing stress could keep soil nitrogen levels low. The nutrient argument still lacks direct experimental support.

The quest of conservationists for biotic diversity becomes even more complex when one considers the zoological aspect of the problem. For invertebrates in particular, microclimatic diversity (which is a function of vegetation structural complexity) is an overriding influence upon the potential faunal diversity. It is not surprising, therefore, that Morris demonstrates a positive correlation between the number of species of *Auchenorhyncha* and the vegetation height at the sampling sites. It does, however, pose a management problem, since in selecting a management regime which determines vegetation height, one must choose between floral and faunal diversity.

Proteins and odour perception in insects

from our Insect Physiology Correspondent

THERE have been several suggestions that enzymatic processes are involved in olfactory perception in insects. Schneider observed that the antennae of the male silkworm rapidly degrade the sex pheromone bombycol following stimulation; and Kasan and Kaissling confirmed that bombycol, (E)-10-(Z)-12-hexadecadien-1-ol, was progressively degraded into acidic and ester fractions by enzymes in the antennae and other parts of the body. In this way the receptors quickly become competent once more to receive the olfactory stimulus. Norris, Ferkovich and others have shown that naphthoquinones, which function as feeding inhibitors in the cockroach *Periplaneta*, exert their activity by binding to sulphydryl groups of specific antennal proteins.

Ferkovich, Mayer and Rutter (*J. Insect Physiol.*, **19**, 2231; 1973) have now studied the sex attractant of the cabbage looper, *Trichoplusia ni*, along the same lines. This pheromone is (Z)-7-dodecen-1-ol acetate. When exposed to a soluble protein present in the male antennae it suffers enzymatic conversion to the alcohol (Z)-7-dodecen-1-ol—which not only lacks sex attractancy but is a potent inhibitor of behavioural responses to the normal pheromone. The protein responsible for enzymatic hydrolysis of the pheromone exists in smaller amounts elsewhere in the body, but it is most active in the antennae. The inhibitory alcohol also reacts, non-enzymatically, with the antennal protein; and both these interactions seem to be necessary for olfactory perception by the cabbage looper.

The close analogies between olfaction and juvenile hormone activity have been pointed out (*J. Insect Physiol.*, **15**, 73; 1969). The hormone likewise must be rapidly inactivated if it is to be kept under control; and the chief mode of inactivation is by means of an esterase which hydrolyses the terpenoid ester to the carboxylic acid, which is devoid of hormonal activity.

KCN and photosystem one

from our Photosynthesis Correspondent

THERE now seems to be no doubt that KCN inhibits photosynthesis by specifically blocking electron flow through photosystem one (S1). It has long been recognised that KCN will inhibit photosynthesis but its mode and site of action have not been clearly understood. Izawa *et al.* (*Biochim. biophys. Acta*, **314**, 328; 1973) now convincingly demonstrate that this compound inhibits electron transfer between cytochrome *f* (cyt *f*) and P700.

Izawa *et al.* used differential spectrophotometry and electron paramagnetic resonance (EPR) to monitor changes in the redox states of these two components which are closely associated with S1 activity. Oxidation of the S1 reaction centre can be detected either by an absorbancy change at 700 nm (for this reason it is called P700) or as an EPR signal with a *g* value of 2.0025. Cyt *f* acts as an electron donor to P700 and is oxidised by light preferentially absorbed by S1 (S1 light). When photosystem two (S2) light is superimposed on S1 light the oxidation levels of cyt *f* and P700 are reduced. These were classical observations first made in Duysen's laboratory in Holland some years ago which clearly demonstrated that S1 and S2 act in series and that cyt *f* and P700 are on the reducing side of the S2 water splitting reaction centre. As expected it was found that in the presence of 3-(3,4-dichlorophenyl)-1, 1-dimethylurea (DCMU), a compound which blocks electron flow from S2 to S1, the reduction of oxidised cyt *f* and P700 by S2 light was inhibited.

Izawa *et al.* were able to demonstrate these properties in their spinach chloroplast preparations, but when the chloroplasts were incubated with KCN, S1 light only photo-oxidised P700 and not cyt *f*. Moreover, when cyt *f* was chemically oxidised the action of S2 light was to reverse this oxidation. On the other hand KCN severely restricted the net flow of electrons from S2 to photo-oxidised P700. These observations indicate without doubt that KCN acts by blocking electron flow between cyt *f* and P700. Izawa and colleagues argue that KCN interacts with plastocyanin, as suggested from *in vitro* experiments, and that this copper containing protein is the intermediate electron carrier between cyt *f* and P700.

Their general ideas have additional support from experiments involving the use of the artificial electron doning agents, diaminodurene, reduced 2.6-dichlorophenol indophenol and reduced N-methylphenazonium methosulphate (PMS) all of which bring about the reduction of oxidised cyt *f* and P700 in DCMU insensitive reactions. It was found with these artificial systems that KCN usually inhibited the reduction of P700 but not cyt *f* although leak past the KCN block was obtained in some conditions such as high PMS concentrations (>30 μM). Unlike normal electron flow this component did not support photophosphorylation.

This work of Izawa *et al.* not only gives good support to an old argument that cyt *f* is not the primary electron donor to S1 but also demonstrates that KCN can be used as a new and powerful tool for investigating S1 reactions in isolated coupled chloroplasts.

Satellites advance geodetic research

from a Correspondent

UNDER the auspices of the International Association of Geodesy, an important symposium on the Earth's gravitational field and secular variations in position was held in Sydney from November 26 to 30.

Through the Earth and Ocean Physics Applications Project (EOPAP) of NASA, the GEOS-C is due to be launched in 1974, and will utilise many of the techniques evolved through the ranging reflectors placed on the Moon by the Apollo astronauts. Many of the papers presented at the symposium described techniques for use with such satellites as elevated targets for ranging with pulsed lasers. The astonishingly high accuracy possible with these new methods will shortly become standard expectations in surveying and in geophysical and oceanographic research.

In an invited presentation, P. V. Angus-Leppan (University of New South Wales) assessed the future prospects for "four-dimensional geodesy", a term which describes the new high-precision techniques for providing position and gravity, and their changes within a short time span. He pointed out that the accuracies of one part in 10^8, which are being approached in these measurements, will shortly allow direct measurements of the velocity of movements of continental plates; from geological inference these plates are currently believed to be moving at a rate of about a few centimetres per year. To achieve the required accuracy, a network of observing stations must be set up on a global scale with international coordination. Angus-Leppan said that each station would constitute the fundamental geodetic observatory for its region and it would include, in a set of comprehensive facilities, laser ranging systems to both the Moon and artificial satellites, an antenna for interconnecting stations by very long baseline interferometry (VLBI), Doppler satellite instruments and a base for absolute gravity measurements.

Progress in the VLBI technique was discussed by several contributors. P. F. MacDoran (Jet Propulsion Laboratory, California Institute of Technology) reported that observations of intense extragalactic radio sources (notably QSOs) with two separated dish antennas operating at S-band wavelengths (13 cm) gave accuracies of a few centimetres for three-dimensional surveying over short separations of 16 km. In addition to measuring variations in universal time, intercontinental baselines (8,400 km) have been measured in VLBI tests between Goldstone, California, and Madrid, Spain. MacDoran predicted that, if a transportable 9 m diameter dish antenna were operated in conjunction with a fixed dish, like the 64 m ones at Goldstone and Madrid, accuracies of a few centimetres in three-dimensional positions would be practical for separations of up to several hundred kilometres, using X-band wavelengths (4 cm).

The importance of accurately calibrated measurements of position and gravity with time was emphasised by the geophysically-minded delegates. These measurements lead to estimates of slow, yet important, lateral and vertical velocities of crustal plates. Direct tests will then be possible for recent theories for predicting earthquakes related to dilatancy of rocks. Four Americans (D. E. Smith, R. Kolenkiewicz, R. W. Agreen and P. J. Dunn) described SAFE which has recently started to use satellite ranging techniques for measuring the motion between two points 900 km apart on opposite sides of the San Andreas fault system in California. Over a 7-yr period, the experimenters believe they will determine the average relative motion of the two sides of the fault to an accuracy of about 5 mm yr^{-1}.

The geoid is defined as the equipotential surface of the Earth's gravitational field corresponding to 'mean sea level', but, as R. S. Mather (University of New South Wales) pointed out, geodetic levelling results and mean sea level (as defined by tide gauge readings) do not correspond. The 'mounds' in the sea, with amplitudes of up to 2 m and wavelengths as great as 8,000 km, produce a topography of the sea surface. This leads to problems in geodesy because of the reliance on mean sea level as a reference datum for elevation. Mather indicated ways of solving this problem by using the precise radar altimeters in the satellites of the forthcoming EOPAP project. If confirmed and when mapped on a global scale, the topography of the sea surface will provide information for predicting ocean currents—a potential boon for more economic navigation of commercial shipping.

J. D. Boulanger (Institute of Physics of the Earth, Soviet Academy of Sciences) tackled the complex problem of the observed variations in gravity with time, and the interpretation of these data in terms of, for example, tectonic processes occurring within the Earth's interior. Yet, according to Boulanger, significant data on this point are scanty. So he proposed an international programme for studying the precise variation of gravity with time throughout the world. He described a 10-yr programme being established in the Soviet Union with a network of gravimetric stations of high precision in the territory of Eastern Europe and the west of the Asiatic part of the Soviet Union.

The network will be based on Sèvres, near Paris. Sèvres has been chosen by the Russians because, Boulanger said, this is the only place where an absolute result for a rate of change of gravity with time has been obtained. The experimenter responsible for this result, A. Sakuma (Bureau Internationale des Poids et Mesures) described the determinations of absolute gravity made by his team; the precision of their measurements is almost one part in 10^9.

Pioneer 10 exceeds expectations

THE remarkable pictures of Jupiter received from Pioneer 10 are alone sufficient to ensure that the mission is remembered as a success, even without data from the other experiments on board the spacecraft. It will take some time for details of these data to emerge; but the simple fact that Pioneer 10 passed unscathed through Jupiter's magnetosphere is itself enough to require understanding of the planet's radiation belts to be rethought.

Most astronomers expected the spacecraft to suffer some damage when it encountered energetic particles trapped in the Jovian magnetosphere, and some suggested that the experiments and telemetry would be rendered completely useless. But a few voices suggesting the opposite view were raised, and two papers in the issue of *Science* dated December 7 (four days after Pioneer 10's closest approach to Jupiter) show the extremes of opinion which co-existed before the spacecraft's encounter with the planet. Stansberry and White describe (*Science*, **182**, 1020; 1973) a model of the trapping of electrons and protons from the solar wind by the magnetic field of Jupiter which implies very high particle densities in the radiation belts, reaching levels 100 times greater than those used in the design of Pioneer 10. "This indicates", they said in the paper, "that there is a significant chance of radiation damage to the spacecraft".

Clearly, they were wrong. And a clue to just how their calculations were in error comes from a study by Hess, Birmingham and Mead (*Science*, **182**, 1021; 1973) of the effect of Jupiter's satellites on the particle fluxes in certain parts of the Jovian magnetosphere. Three of the Galilean satellites, in particular, turn out to be very effective in limiting the fluxes of energetic protons and electrons diffusing inward. Ganymede, Europa and Io all produce "precipitous" drops in the flux, so that the average flux in the plane in which these satellites lie "should be about a factor of 100 less than . . . if there were no absorbing moons". Hess and colleagues suggest that "This may be enough to prevent serious radiation damage to the spacecraft", and it now looks as if they were right.

Jupiter's red spot, a shadow of the Moon Io and Jupiter's cloud structure are shown in this photograph taken on December 1 as Pioneer 10 was about 2,500,000 km (1,580,000 miles) from the planet.

The importance of this, of course, extends beyond the satisfaction of having an idea proved right. It seems clear from the success of Pioneer 10 that spacecraft can approach fairly close to Jupiter without being severely damaged, and the presence of a satisfactory theory to account for the low particle fluxes encountered by the spacecraft suggests that similar low flux conditions will be encountered by other spacecraft following suitable trajectories. The need for close encounters is two-fold: first, it enables spacecraft to take an advantage of Jupiter's gravity in directing them on to Saturn and the other gas giants; second, with the present state of the art a Jupiter rendezvous mission, leaving a spacecraft in orbit around the planet, can only be achieved by firing the spacecraft's motors when it is deep in the Jovian gravitational well. So Pioneer 10 has lived up to its name by showing the way for future missions to the outer reaches of the Solar System.

Code of practice for radiation protection

from a Correspondent

A MEETING in London on November 14 was arranged jointly by the British Institute of Radiology and the Hospital Physicists' Association to provide a forum for discussion of the requirements and implementation of the 1972 revision of the Code of Practice for the Protection of Persons against Ionising Radiations arising from Medical and Dental Use.

The morning session was concerned with the main provisions of the new code and difficulties in its interpretation. J. Cole (Dudley Road Hospital, Birmingham) reviewed the steps leading to the present revision following the publication of the first edition of the code in 1957. He pointed out that the basic policy in formulating the code was "to set out the basic principles, and to give general guidance on good practice".

H. Miller (University of Sheffield) described the changes in the scope of the code and the general protection measures required. He said that the wording of the new code was more precise and the conditions for both essential and desirable requirements had been clarified.

G. M. Ardran (University of Oxford) and S. K. Stephenson (Christie Hospital, Manchester) then outlined the changes in the code relating respectively to the medical and physical aspects of diagnostic radiology. The relative responsibilities of the clinician and radiologist in reducing patient exposure were mentioned in relation to the problems of implementing the '10-day rule' for avoiding irradiation of unsuspected pregnancies. Stephenson enumerated some of the twenty-five new obligatory requirements in the code; he felt that reduction of patient dose was the area where improvements could be made.

The measures for increasing protection in radiotherapy were examined by T. J. Deeley (Velindre Hospital, Cardiff); again a more positive identification of hazards was evident in the new code. Leakage radiation from therapy equipment and diaphragm systems were unsatisfactory features leading to unnecessary patient irradiation.

That the section of the code dealing

with unsealed radioisotopes had required and received drastic revision was explained by N. G. Trott (Royal Marsden Hospital, Sutton), although he pointed out that the current revision had not fully kept abreast of recent changes in nuclear medicine technique. N. J. D. Smith (King's College Hospital, London) surveyed a large number of practices and revealed many with many unsatisfactory protection standards. Personnel monitoring had shown consistently high exposures to many dentists and ancillary staff, who were often unaware of the existence of the code of practice. It was reported that few dentists had taken advantage of a recent monitoring scheme launched by the National Radiation Protection Board. The need for a separate, explanatory supplement to the code for dentists was evident.

The afternoon session was devoted to problems in implementing the code, and the achievement of radiation safety in the hospital service. D. C. Holdsworth (United Hospital, Sheffield) thought that clinicians could make an effective contribution in reducing patient exposure, but they needed more information in order to weigh the risks of the radiation procedure against the hazards of omission. C. K. Warrick (Royal Infirmary, Newcastle upon Tyne) described his system for implementing the '10-day rule' in a survey 12 months ago; the rule was practised by only 20% of the departments sampled. Several hospitals had demonstrated that workable systems could be operated to reduce the number of unsuspected pregnancies irradiated.

The responsibilities of the Radiation Protection Adviser in achieving radiation safety were discussed by R. F. Farr (Queen Elizabeth Hospital, Birmingham), and N. Chesney, Farr's colleague, made a plea for a clear statement of the duties of the Radiological Safety Officer and, in many cases, appropriate training for these duties was required.

W. J. Meredith (Manchester Regional Hospital Board) spoke in the unusual guise of administrator, and pointed out that the code put a heavy responsibility on the controlling authority. Apart from the need to keep the numerous formal records required by the code, there was a continuing need to keep radiation safety committees alive and active.

R. D. Moore (Weston Park Hospital, Sheffield) described his attempts to evaluate the cost of protection measures. The annual cost in the United Kingdom of health physics services in the hospitals together with the costs of structural shielding amounted to some £580,000 per year. This resulted in a consequential saving of 140,000 man-rads, that is about £4 per man-rad saved.

Coulomb-nuclear effects

from our Nuclear Theory Correspondent

AN interesting example of interference between Coulomb and nuclear scattering amplitudes has recently been found in the inelastic scattering of heavy ions by nuclei. This interference can be understood classically in a qualitative way, and can also be calculated accurately using the distorted wave theory.

This interference is made possible by the particular character of the field between heavy ions, which allows incident particles with different classical impact parameters to be scattered through the same angle. To see how this comes about, consider the behaviour of the scattering angle as the impact parameter is steadily reduced.

For large impact parameters the projectile interacts only with the repulsive Coulomb field of the target, and is deflected through a small angle that steadily increases as the impact parameter is reduced. When the distance of closest approach becomes comparable to the sum of the radii of the projectile and target, the nuclear force begins to attract the projectile, thus reducing the scattering angle. At still smaller impact parameters the projectile is repelled by the centrifugal force, thus increasing the scattering angle again. The resulting variation of scattering angle is shown in Fig. 1 for 60 MeV ^{16}O ions on ^{58}Ni.

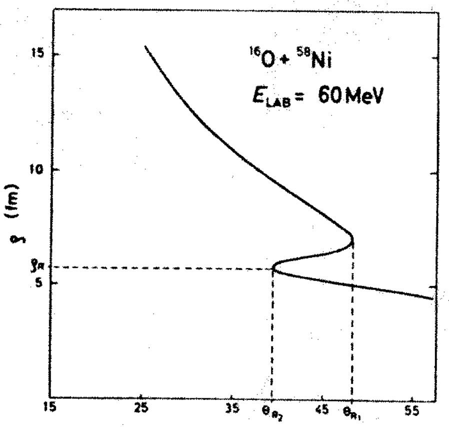

Fig. 1 Variation of the scattering angle θ with the impact parameter ρ for 60 MeV ^{16}O ions on ^{58}Ni (Malfliet, Landowne and Rostokin, *Phys. Lett.*, **44B**, 238; 1973).

In such cases there are three values of the impact parameter corresponding to each scattering angle between the critical scattering angles $\theta(R_1)$ and $\theta(R_2)$. The chief contribution to the scattering comes from angles around the critical angles, so a semi-classical theory can be made by adding the corresponding amplitudes, with appropriate phase and attenuation factors. The turning point corresponding to the larger impact parameter refers to the orbit further away from the nucleus where the projectile is moving mainly in the Coulomb field, whereas the other turning point refers to the orbit nearer the nucleus where the projectile is under the influence of both the Coulomb and nuclear fields. These amplitudes interfere, and because they vary with angle in a different way the interference is sometimes destructive and sometimes constructive.

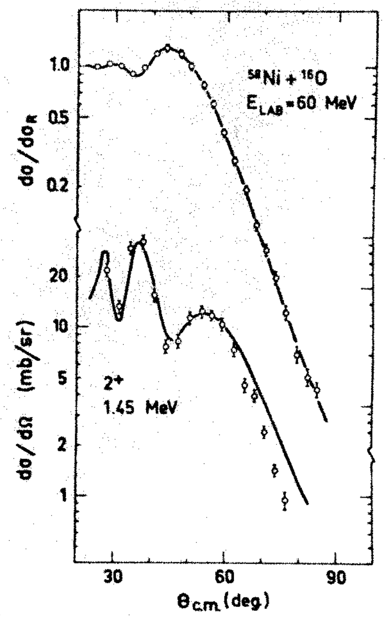

Fig. 2 Differential cross sections for the elastic and inelastic scattering of 60 MeV ^{16}O ions by ^{58}Ni showing the interference effects in the region of the critical angles. The curves are obtained using the distorted wave theory (Christensen, Chernov, Gross, Stokstad and Videbaek, *Nucl. Phys.*, **A207**, 433; 1973).

These effects appear in elastic scattering around the region of the critical angles, but are much more prominent in inelastic scattering. For small angles, the cross section for the excitation of the lowest $J^\pi = 2^+$ state of the target is almost entirely due to Coulomb excitation, while for large angles it is mostly due to nuclear excitation. In the intermediate regions around the critical angles the interference effects are strongly marked as shown in Fig. 2.

The whole process can be described quantitatively by the distorted wave theory, using the appropriate vibrational model for the 2^+ state. The results of such calculations are also given in Fig. 2 and show that the interference effects are accurately given by the theory. Detailed fitting in the interference region gives improved values of the parameters of the distorting potential and of the nuclear dynamical deformation parameter.

This interference phenomenon is a good example of the way interactions between heavy ions can be understood semi-classically and then analysed by the distorted wave theory to give additional information on nuclear structure.

Two Stage Red Sea Floor Spreading

R. W. GIRDLER & P. STYLES

School of Physics, The University, Newcastle upon Tyne, NE1 7RU

Evidence is presented which strongly suggests that most of the southern Red Sea is underlain by oceanic crust which evolved in two stages, the first from about 41 to 34 million years ago and the second from about 4 to 5 million years ago to the present day.

THE Red Sea consists of a main trough and a young axial trough which starts at about 24° N and widens towards the south[1]. Unfortunately, large amounts of sediment obscure the true structures especially in the southern half. It has been clear for some time that the axial trough is underlain by new oceanic crust but there are conflicting views on the nature of the crust underlying the main trough[1–14].

The scant amount of gravity data available in the 1950s was sufficient to show that the axial trough is underlain by a high density intrusive zone[15]. Further geophysical work confirmed the presence of this intrusive zone[1]. Large magnetic anomalies with amplitudes exceeding 1,000 nT were observed over the axial trough and seismic velocities of about 7 km s^{-1} were found at shallow depths of 2 to 3 km. The magnetic anomalies were later interpreted in terms of seafloor spreading and a half rate of 1 cm yr^{-1} was determined for latitude 16° N (ref. 3). It became clear that the Red Sea axial trough is being formed by seafloor spreading, and Arabia and Nubia have been drifting apart for the past 3 to 4 Myr.

The situation regarding the main trough and earlier history of the Red Sea has been much less clear. The fact that in many places the shelves are at or near sea level suggested in the 1950s that they are underlain by Precambrian shield rocks[15]. At that time the large thicknesses of sediments[9,16] were unknown. Further, seismic velocities of 5.9 km s^{-1} were found[1] suggesting the presence of at least some shield rocks. In the mid 1960s, the evidence (previously disputed) for about 100 km shear along the Dead Sea rift became very strong[17]. This 100 km displacement implies that there must be a much greater separation of the Red Sea than the width of the axial trough[2]. Seismic refraction experiments at 22 to 23° N with the objective of finding the extent of the oceanic crust[4,8] showed an average velocity of 6.63 ± 0.16 km s^{-1} at a mean depth of 4.6 km for the main trough, thus establishing the presence of oceanic crust and a minimum separation of Nubia and Arabia of 130 km. But some recent papers[12,14,18] still support the thesis that only the narrow axial trough is oceanic and the main trough and shelves are underlain by downfaulted shield rocks.

New evidence is given here which supports the existence of oceanic crust beneath the shelves of the southern Red Sea. In addition, it is now possible to be reasonably certain about the age of this crust.

New Magnetic Data

In 1966, the Gulf Oil Company flew a detailed total intensity magnetic survey at a height of 610 m over the western margin of the Red Sea between 14.5 and 16° N ; and in 1968, US Project Magnet flew eight lines (four at height 305 m and four at height 3,658 m) from shore to shore at 18° N.

The Gulf survey has excellent navigation control, Shoran being used. The original analogue records have recently been made available and have been digitised with the object of gaining information on the seafloor spreading history of the margins. The profiles were digitised at every Shoran location and additionally at every turning point so as to preserve the details of the records. This gave a digitisation interval of about 0.7 km. A ground magnetometer station was set up at Massawa and the records from here were used to correct for the daily variation. The IGRF 1965.0 gradient was removed from each profile.

For the Project Magnet profiles, Doppler navigation was used and hence these have less good positional control. The records were digitised in a similar way and the IGRF 1965.0 gradient removed.

Nine of the sixty Gulf profiles (G11, G16, G20, G25, G31, G35, G40, G44 and G50) and two of the eight Project

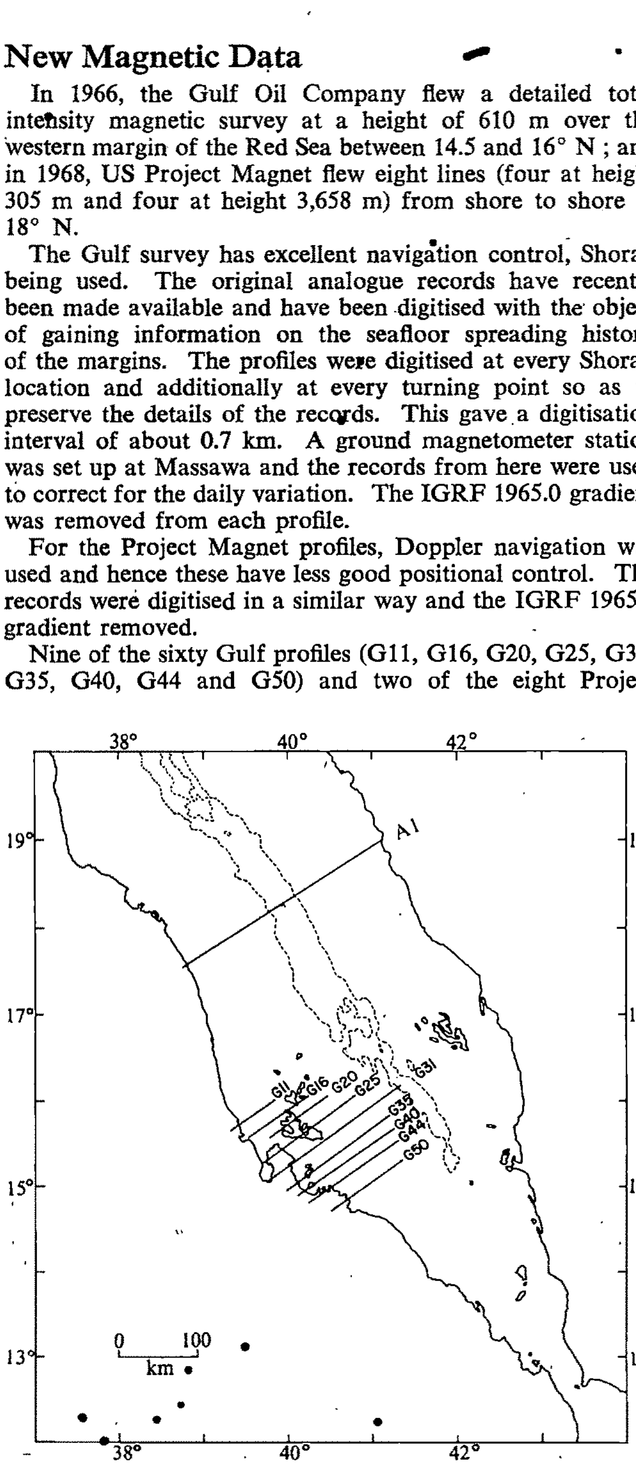

Fig. 1 Location of total intensity magnetic profiles. The dashed [illegible] are the 500 and 1,000 fathom contours taken from the 1 : 2 million bathymetric chart of Laughton[25].

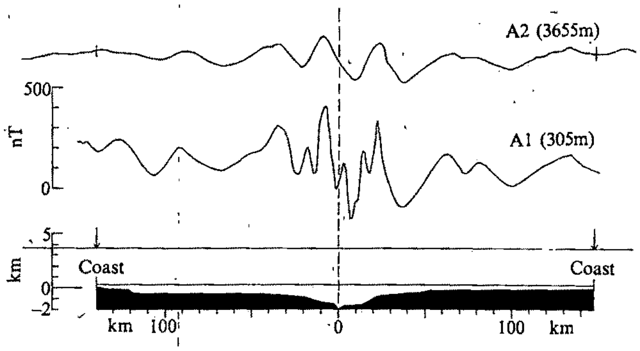

Fig. 2 Project Magnet profiles across the whole width of the Red Sea at 18° N showing the existence of magnetic anomalies on either side of the axial trough associated with symmetrical spreading (compare Fig. 5) and their relationship to the bathymetry.

Magnet profiles (A1 and A2) are used to illustrate the seafloor spreading history of the Red Sea. The locations of the profiles are shown in Fig. 1. A2 (height 3,655 m) has almost the same location as A1 (height 305 m).

Interpretation of Magnetic Anomalies

Figures 2 and 3 show two sets of examples of magnetic anomalies over the Red Sea. Figure 2 has two profiles flown at different heights from shore to shore (Project Magnet) showing the relationship of the anomalies to the bathymetry. Figure 3 shows a set of nine profiles over the western margin (Gulf Oil Co.). Taken together, these provide convincing evidence for the presence of oceanic crust beneath nearly all of the southern Red Sea.

First, the Project Magnet profiles (Fig. 2) show the familiar large anomalies over the axial trough and also the existence of anomalies over the main trough. It should be remembered that the computed anomalies for a normally magnetised body with the northwesterly strike of the Red Sea show a positive anomaly over its western edge and a negative over its eastern edge (a reversely magnetised body has a negative over the western edge and a positive over the eastern edge). When consideration is given to this, it is apparent that the anomalies are due to symmetrically emplaced bodies (Fig. 5) and the symmetry is impressive evidence that the anomalies are due to seafloor spreading. Figure 2 also shows a contrast in the amplitude of the anomalies over the axial trough and those over the margins suggesting two different phases of spreading. Further, the large anomalies are not exactly confined to the axial trough but extend somewhat further. Possible reasons for this are discussed by Girdler and Whitmarsh[19].

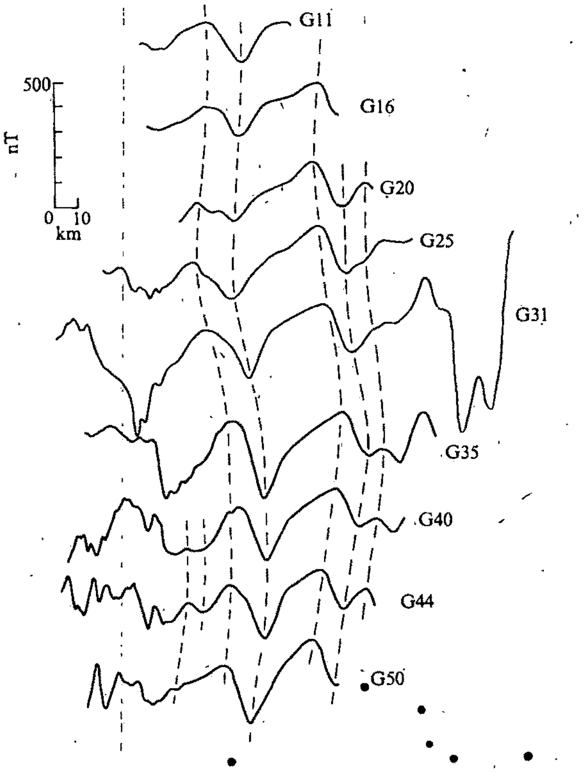

Fig. 3 Nine profiles from the Gulf magnetic survey illustrating the two types of anomalies, the smooth long wavelength well correlated anomalies over the Red Sea and the poorly correlated high frequency anomalies in the west.

Second, the Gulf profiles (Fig. 3) show that the anomalies on the western side of the axial trough are remarkably consistent and can be linearly correlated over a distance of at least 230 km. This would be very unusual for anomalies over shield rocks and provides additional evidence for their seafloor spreading origin.

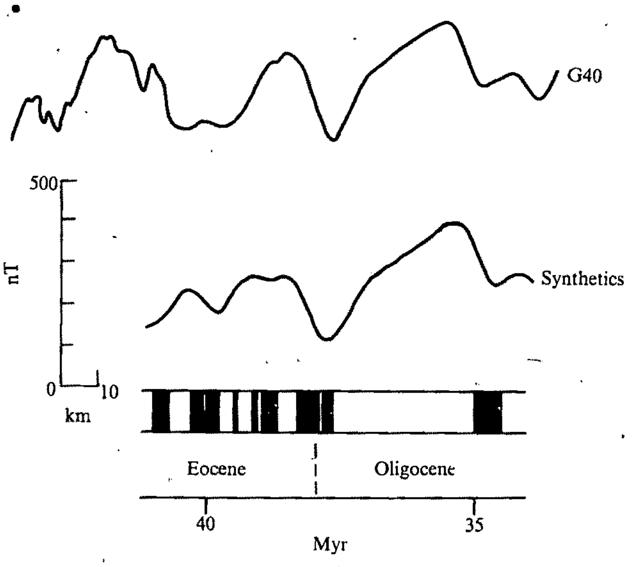

Fig. 4 Synthetic and observed profiles for Gulf profile G40. The synthetic profile is for a spreading rate of 1.4 cm yr^{-1} and strike N 120°.

Third, the Gulf profiles (G25, 31, 35, 40, 44 and 50) show a contrast between two types of anomalies—high frequency poorly correlated anomalies in the west and long wavelength well correlated smooth anomalies in the east over the Sea. Almost certainly the former are over Precambrian shield and the latter over seafloor.

Age of Red Sea Floor

Synthetic profiles were generated for the Red Sea using the reversal time scale of Heirtzler *et al.*[20]. At first, attempts were made to obtain an interpretation similar to that for the Gulf of Aden[21], that is, a continuous spreading history back to anomaly 5 (10 Myr). The correlations beyond 3 to 4 Myr were found to be very poor, as found by Vine[3]. The synthetic profiles were then extended back to the base of the Miocene (25 Myr) using various spreading rates and again good correlations could not be found. Finally, synthetic profiles were generated back to 70 Myr and searched for possible correlations with the observed anomalies.

A remarkably good correlation was found for the time interval 34 to 41 Myr. This is illustrated in Fig. 4 using Gulf profile G40. A spreading rate of 1.4 cm yr^{-1} over this time interval gives excellent correlations with the observed data. The long reversal interval (35.00 to 37.61 Myr) is necessary to obtain the characteristics of the Gulf profiles. Other possible candidates for this long reversal interval are even older (for example, 49.58 to 52.41 Myr) but for these the fits for the neighbouring anomalies are not nearly so good. It is therefore proposed that the oceanic crust to the sides of the axial trough is surprisingly old, being about 34 to 41 Myr (late Eocene to early Oligocene).

New Model for the Red Sea

A new geophysical model for the Red Sea is presented in Fig. 5. This utilises the shore to shore Project Magnet profile A1, the location of which is shown in Fig. 1. Various data such as thickness of sediments and seismic refraction profiles suggest that the old crust is at a depth of about 5 km and the new crust at about 2 km. The synthetic magnetics is compared with the observed. The fit of the anomalies for the older crust is not quite so good as for the Gulf data and this is considered to be partly due to the poorer navigation. The old phase is shown to end at about 34 Myr and the new phase to begin at just over 4 Myr. There is, of course, some uncertainty about these dates. It seems highly probable that the new phase of spreading may have commenced at the end of the Miocene (4.9 Myr ago[22]) when the whole sedimentary environment changed with the opening of the southernmost Red Sea to the Indian Ocean.

Support for the two stage model also comes from seismic reflection profiling[6,18]. The acoustic reflector (S) is now known from Deep Sea Drilling to be anhydrite and to represent the top of the Miocene[23]. This reflector is absent in the axial trough suggesting a second phase of spreading after the Miocene.

The model of Fig. 5 is in broad agreement with the heat flow seafloor spreading models of Sclater and Francheteau[24]. The axis of the Red Sea has very high heat flow consistent with the generation of new oceanic crust and the heat flow over the sides is slightly high[9] consistent with older oceanic crust.

Plate Tectonics

Figure 6 depicts a map of the Red Sea (Mercator projection) based on the 1:2 million bathymetric chart of Laughton[25] and showing the 500 and 1,000 fathom contours. The ages of the oceanic crust deduced from the magnetic profiles have been transferred to the map. For the Project Magnet data (18° N) the isochrons for the new phase of spreading are fairly easily correlated over all the profiles. It is less easy to correlate the anomalies for the old phase of spreading especially on the eastern side and the 35, 37 and 39 Myr isochrons are thus shown with dashed lines.

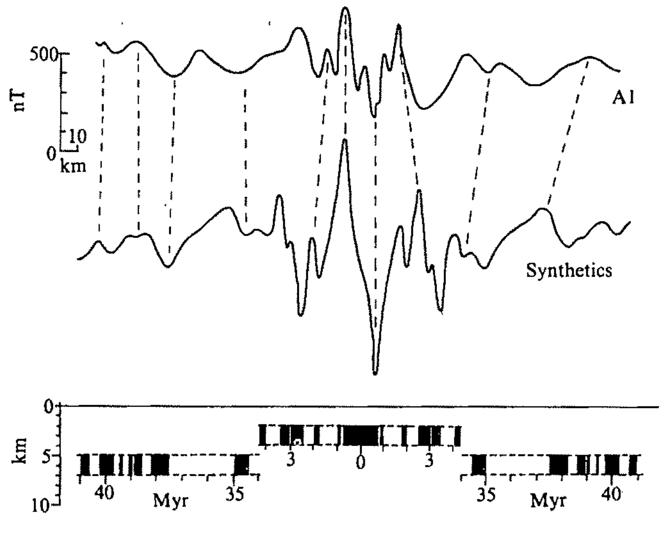

Fig. 5 A new geophysical model for the Red Sea (18° N) with two phases of seafloor spreading, the first (1.3 cm yr^{-1}) being in the late Eocene/early Oligocene and the second (0.9 cm yr^{-1}) being over the past few million years and still continuing.

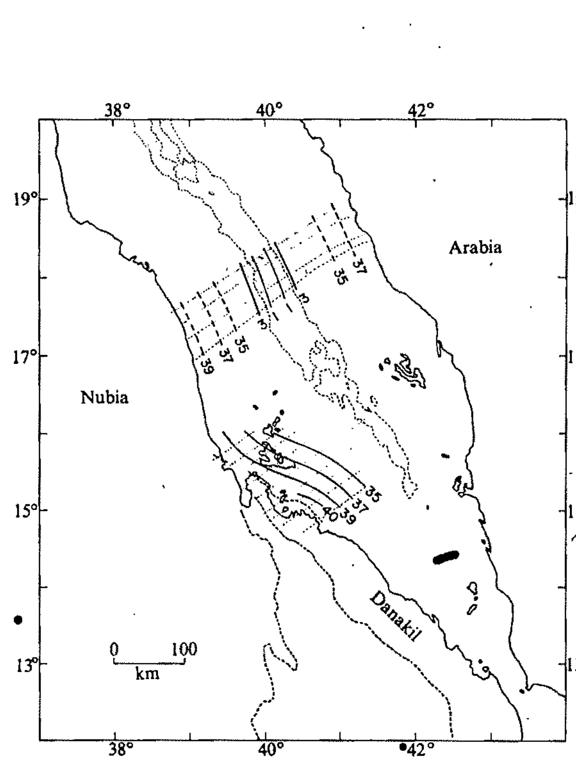

Fig. 6 Isochrons (Myr) for the ages of oceanic crust beneath the Red Sea. The dashed lines are less certain than the solid lines. The dotted lines are flight tracks.

From the Gulf magnetic profiles it is possible to locate the 35, 37 and 39 Myr isochrons with some confidence and to tentatively mark the oceanic/continental boundary of the Danakil plate. The isochrons bend southeastwards in this region. This is presumably because the Danakil plate was rotating counterclockwise with respect to the Arabian plate during this early phase of spreading. The anomalies can be seen to be closer towards the south (Fig. 3) especially for profiles G25 to G50. This is to be expected if Danakil was rotating with respect to Arabia during this time interval. To the north, away from Danakil, the anomalies are related to the counterclockwise rotation of Arabia with respect to Nubia.

Geological History of the Red Sea

In view of the evidence given here for an early phase of seafloor spreading, it is necessary to present a new summary of the geological history of the Red Sea and check that the model given in Figs 5 and 6 is consistent with the geological data. In particular, the geological summary[26] given by Girdler needs substantial revision (Fig. 7). The most important change is in the date of formation of the main Red Sea graben previously given as end of Oligocene/early Miocene, that is, about 26 Myr.

In the geological review given by Heybroek[27], it is reported that some kind of depression may have existed as early as Carboniferous times. The first major rift movements seem to have been in the lower/middle Eocene. Following these, a major phase of seafloor spreading occurred in the late Eocene and early Oligocene. This was followed by a long quiet period of about 30 Myr during which time huge thickn[illegible]f sediments, mainly evaporites, were deposited.

Fig. 7 Geological history of the Red Sea.

From oil company data[12], the thickness of bedded evaporites is estimated to be as much as 5 km. Some K/Ar dates are available[12] from exploration wells in the south-west Red Sea (about latitude 16° N). These are 36.4±2 Myr and 36.6±2 Myr for the Amber well bottomhole core consisting of slightly metamorphosed very pyritic argillite and an average of 30 Myr for the bottomhole basalt core of well B1. These ages are no longer embarrassing, for it is now evident that the early stage of the Red Sea was in existence at least 40 Myr ago.

After the long 30 Myr quiet period of deposition, a new period of activity started about 5 Myr ago. The whole sedimentary environment suddenly changed at the end of the Miocene; nanno oozes were deposited instead of evaporites as the Red Sea became connected to the Gulf of Aden and Indian Ocean via the Straits of Bab-el-Mandeb. Seafloor spreading recommenced along the centre giving rise to large magnetic anomalies and very high heat flow. The axis of the Red Sea is seismically active and the process is still continuing[28]. The axial deep trough (Fig. 2) is due to the separation of old oceanic crust plus overlying sediments. The new oceanic crust beneath the axis reaches to within 2 to 3 km of sea level because of its higher temperature. The new phase of spreading caused considerable disturbance of the sediments with the creation of a very unstable situation as the crust and sediments parted and the axial trough evolved[19].

Some Implications

Finally, some implications concerning the possible existence of two stage Red Sea floor spreading are given.

The first concerns the Dead Sea rift. Freund *et al.*[29] find evidence for about 105 km shear, the whole of which can be dated as post-Cretaceous (about 65 Myr). This movement took place in two stages, the last 40 to 45 km being post-Miocene/early Pliocene. This correlates well with the second (recent) phase of spreading in the Red Sea. It has not yet been possible to date the remaining 60 km of shear[29] and it now seems likely that this was late Eocene/lower Oligocene corresponding to the first major phase of spreading in the Red Sea. It is to be hoped that Middle Eastern geologists will look for evidence to confirm this.

The second concerns the Gulf of Aden. Since little or no shear has been observed along the Ethiopian rift (between the Nubia and Somalia plates) it is to be expected that the history of the Gulf of Aden should be similar to that of the Red Sea. The interpretation of continuous seafloor spreading over the past 10 Myr in the Gulf of Aden[21] depends largely on the correct identification of anomaly 5 (not identified in the Red Sea). The magnetic profiles are therefore being re-examined to see if the two stage Red Sea spreading model also applies to the Gulf of Aden. Whitmarsh (personal communication) points out that as anomaly 5 is correlated into the north-west Indian Ocean, this is also in question. It may be that magnetic profiles over the oceans should be carefully re-examined for evidence of go-stop-go seafloor spreading.

Lastly, the Afar region (bordered by the Nubia, Somalia and Danakil plates) has been a popular location for a mantle hot spot. If hot spots provide the driving mechanism for plates, the evidence presented here suggests that this hot spot was active about 40 Myr ago, died for 30 Myr and relit about 5 Myr ago! This seems somewhat unlikely and it seems more likely that the intermittent plate motions of Arabia, Nubia, Danakil and Somalia are a consequence of more mantle wide convective motions.

We thank the US Naval Oceanographic Office and the Gulf Oil Co. for making available the original magnetometer records and for giving us permission to publish the profiles shown here. In particular, we acknowledge the help of Drs Henry Stockard and Patrick Taylor (USNOO) and Drs J. P. Huie (vice-president), A. C. Armstrong, M. D. Beltrandi and A. Pyre (Gulf). Stuart Hall helped with the digitisation of the Project Magnet records.

Isolation of Bovine Thymin: a Polypeptide Hormone of the Thymus

GIDEON GOLDSTEIN
Department of Pathology, New York University School of Medicine, New York, New York 10016

Two closely related polypeptides termed thymin I and II were isolated from bovine thymus by their effect in causing a delayed impairment of neuromuscular transmission *in vivo*. Purified thymin also induced bone marrow cells to develop the characteristics of intrathymic lymphocytes and it is probable that thymin is a lymphopoietic differentiating hormone of the thymus with secondary neuromuscular effects.

THE thymus is a compound organ consisting of an epithelial stroma derived from the third branchial arch and lymphocytes derived from stem cells originating in haemopoietic tissues (see ref. 1 for review). Lymphocytes differentiated within the thymus leave as mature thymus-derived cells (T cells) which circulate to the blood, lymph, spleen and lymph nodes. The induction of stem cell differentiation within the thymus is probably mediated by secretions of the epithelial cells of the thymus[2] but difficulties with bioassays have hindered the complete isolation and structural characterisation of these hormones[3–6].

A different approach to the isolation of thymic hormones was developed from experimental studies related to the human disease myasthenia gravis. Myasthenia gravis is characterised by a deficit in neuromuscular transmission and an associated thymic pathology has long been recognised in this disease. A study of clinical, pathological and immunological features of myasthenia gravis led to the hypothesis that thymic autoimmune disease is the lesion basic to this disease[7,8]. A laboratory animal model of experimental autoimmune thymitis was developed and these animals were shown to have an abnormality of neuromuscular transmission similar to that of myasthenia gravis by a number of criteria[9–14]. Experimental analysis of this laboratory model revealed that the effect on neuromuscular transmission was mediated by a substance released from the diseased thymus[9,13,14]. Neurophysiological studies in thymectomised and thymus grafted animals suggested that this substance was secreted physiologically[15]; and so the name thymin was proposed for this putative hormone.

The hypothesis of a neuromuscular blocking substance in the thymus is not novel; it was proposed in 1943 (ref. 16) in relation to the then current concepts of the curare-like nature of the myasthenic neuromuscular block, the known association of thymic pathology with the disease and the empirical discovery that thymectomy was an effective treatment for myasthenia gravis[17,18]. An unequivocal demonstration of such a neuromuscular blocking substance was not, however, obtained despite a large body of experimental work (reviewed in ref. 1). Although no consistent acute effects of thymus extracts could be demonstrated it was found that when thymus extracts were injected into animals impairment of neuromuscular transmission could be detected after a delay of several days[19]. This effect of a delayed production of impairment of neuromuscular transmission has served as a bioassay for monitoring the chemical fractionation of bovine thymus extracts.

I shall describe the isolation of two closely related polypeptides which produce, following a single injection of 4–32 ng per mouse, an impairment of neuromuscular transmission detectable by electromyography 1–5 d following injection. Of particular interest is the finding that these purified polypeptides also induce differentiation of bone marrow cells to T cells and hence seem to be thymic hormones which induce differentiation of the lymphopoietic stem cells which give rise to thymus-derived lymphocytes (T cells) (R. S. Basch and G. Goldstein, in preparation).

Assay Systems

Extracts were injected into test animals and neuromuscular transmission was studied after an interval of 1–5 d. Initially 100 g guinea pigs were injected intraperitoneally; neuromuscular transmission was studied *in vitro* with a preparation of the phrenic nerve and hemidiaphragm[19]. Subsequently 200 g rats were used; fractions were injected subcutaneously and neuromuscular transmission was assessed electromyographically[12]. Finally, mice were found to be an effective test system. Female Swiss-Webster mice weighing 25–35 g were injected intraperitoneally, groups of five to ten mice being used to test each fraction. The animals were anaesthetised with urethane and electromyography was performed as described previously[11]. The muscle action potentials were recorded in each mouse following supramaximal nerve

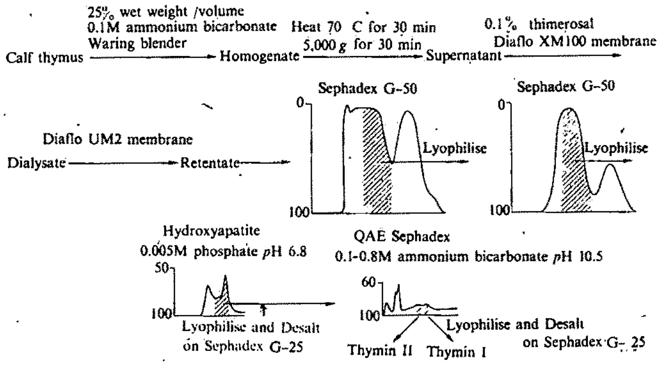

Fig. 1 Flow chart showing steps in the isolation of thymin I and II from bovine thymus. The chromatographic elution profiles are of transmittance at 254 nm and the shaded areas represent the fractions collected.

stimulation with ten impulses at a rate of 50 s^{-1}. Five sites were sampled in each mouse and for each group of mice the mean standard deviation and s.e.m. were calculated for the change in the height of the muscle action potential generated by the first and tenth impulses, the height of the tenth impulse being expressed as a percentage of the height of the first impulse.

Since this response in normal mice was found to vary somewhat with age and size, appropriate controls from the same group of mice were always tested. The statistical significance of differences found was assessed by Student's *t* test.

Purification procedures were also monitored by analytical polyacrylamide disc electrophoresis; 7% polyacrylamide gels were run at *p*H 8.9 and *p*H 4.3[20]. Methyl green was used as a dye marker in the acid gels run towards the cathode and bromophenol blue was used in the basic gels run towards the anode. Spacer gels were not used, the samples being loaded in electrode buffer made up with the dye marker in 25% sucrose. The gels were fixed in 12.5% trichloroacetic acid, stained with Coomassie blue and the relative mobilities (R_F) were calculated with respect to the dye markers.

The isolation methods are summarised as a flow chart in Fig. 1. Bovine thymus was obtained fresh on wet ice, dissected clean and stored at −20° C. Batches were homogenised 25% wet weight/volume in 0.1 M ammonium bicarbonate using a Waring blender. The extract was heated to 70° C for 30 min in a water bath, then centrifuged at 5,000*g* for 30 min. The supernatant was filtered through gauze and cotton and 0.1% thimerosal was added as a bacteriostatic agent since the subsequent steps were carried out at room temperature. Diaflo membranes (Amicon) and molecular sieve chromatography on Sephadex (Pharmacia) were used to obtain an enrichment on the basis of molecular size. The extract was processed through a Diaflo XM100A membrane in a TC10 apparatus. The dialysate was then concentrated over a Diaflo UM2 membrane, using a 402 cell pressurised to 55 pounds per square inch; 2 l was concentrated to 15 ml. This retentate was further fractionated by molecular exclusion chromatography on a 2.5×100 cm column of G-50 medium Sephadex (Pharmacia) in 0.1 M ammonium bicarbonate. The outflow was monitored with a Uvicord I monitor (LKB) which recorded ultraviolet transmittance at 254 nm. The fractions shown in Fig. 1 were lyophilised and rerun on the same column.

The lyophilised fractions from G-50 Sephadex were fractionated by adsorption chromatography on hydroxyapatite (Biorad). A 500 mg load was dissolved in 0.005 M sodium phosphate buffer, *p*H 6.8, and applied on a 2.5×30 cm column of hydroxyapatite in the same buffer. Active fractions were found retarded behind the void volume (Fig. 1); they were lyophilised and desalted on a G-25 Sephadex column. This material was fractionated further by ion exchange chromatography on a 1.5×30 cm column of QAE-Sephadex (Pharmacia) in 0.1 M ammonium bicarbonate brought to *p*H 10.5 with ammonium hydroxide. The column was developed with a linear concentration gradient to 0.8 M ammonium bicarbonate, also brought to *p*H 10.5. The two fractions shown in Fig. 1 were active in producing neuromuscular block. These were designated thymin II and thymin I (see below) and each was lyophilised and desalted on G-25 Sephadex in 0.1 M ammonium bicarbonate; the lyophilised void volume of these columns constituted the purified thymins. If these fractions were still impure on analysis by polyacrylamide disc electrophoresis the ion exchange chromatography step was repeated.

The yields varied somewhat from batch to batch; on average 1 kg of wet thymus yielded 500 mg of lyophilised powder after the Sephadex G-50 steps; this yielded 50 mg after hydroxyapatite adsorption chromatography and the final yield was approximately 1 mg of each thymin.

The electromyographic assay was adequate to detect peaks of activity during fractionation. Due to the eventual finding of two polypeptides, with slightly different thresholds of action and due to the wide variations in normal electromyographic responses which required large numbers of test animals and controls to assess variations statistically, it was, however, not possible to quantify enrichments and yields of activity for each step of the isolation.

Neuromuscular Action of Thymin

The electromyographic response of mice 5 d after various doses of thymin I or thymin II is summarised in Fig. 2. Bovine serum albumin (0.5 mg per ml 0.9% saline) was used as a protein stabiliser and controls were injected with the solvent alone.

In fifteen control mice tested at seventy-five muscle sites the tenth muscle action potential was 94±2% (mean±s.e.m.) of the first. For groups of mice (4–10) given varying doses of thymin I or II there was a statistically significant ($P<0.001$) augmentation of the degree of decrement at most doses above a threshold which was 4 ng per mouse for thymin I and 32 ng per mouse for thymin II. The degree of neuromuscular impairment did not increase with increasing dose above the threshold and the mean response for all mice given suprathreshold amounts of thymin was 84% for thymin I and 82% for thymin II (Fig. 2).

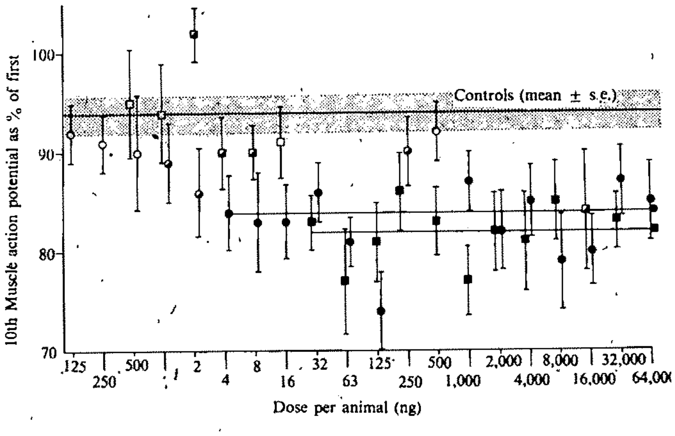

Fig. 2 Chart showing the electromyographic response of mice to supramaximal nerve stimulation at a rate of 50 impulses s^{-1}. The mean values and s.e.m. (vertical bars) are shown for groups of 4–10 mice given various doses of thymin I (○) and thymin II (□). Statistical significances of differences from the controls were calculated by Student's *t* test and are shown by solid symbols ($P<0.001$), half solid symbols ($0.05>P>0.001$) and open symbols ($P>0.05$).

Mice were given 100 ng of thymin I or solvent and five mice from each group were tested at various times. A statistically significant ($P<0.001$) effect on neuromuscular transmission was first detected 18 h after injection, became maximal by 24 h and persisted through 5 d (Fig. 3).

Relationship of Thymin I and Thymin II

During the development of the isolation procedures for thymin, the purity of fractions was assessed by polyacrylamide disc electrophoresis at *p*H 8.9. Neuromuscular blocking activity was found associated with material which stained with Coomassie blue, and had an R_F of 0.30 with respect to bromophenol blue (Fig. 4). At *p*H 8.9 thymin I migrated only slightly faster than thymin II. At *p*H 4.3, however, this material resolved into two distinct bands both of which produced neuromuscular impairment (see above). The faster one was designated thymin I (R_F 0.63 with respect to methyl green) and the slower one thymin II (R_F 0.57) (Fig. 4). The mobilities of these purified polypeptides remain consistent and do not interconvert.

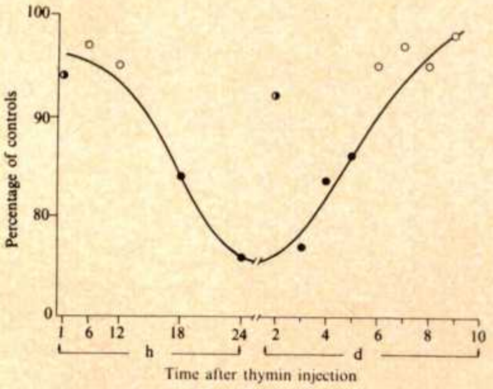

Fig. 3 Electromyographic response of mice at various times after a single injection of 100 ng thymin I expressed as a percentage of the response of mice injected with solvent alone. With supramaximal nerve stimulation at 50 impulses s^{-1} the height of the tenth muscle action potential was expressed as a percentage of the first. This change was calculated for five points in each of five to ten mice from each group. For each time point the change in thymin-treated mice was expressed as a percentage of the change in solvent-treated control mice and the statistical significance of the difference was assessed by Student's *t* test; solid circles: $P<0.001$; half solid circles: $0.05>P>0.001$; open circles: $P>0.05$.

Thymin I and II are polypeptides with molecular weights of approximately 7,000, based on their characteristics in molecular sieve chromatography and their amino acid compositions. Preparations of thymin I and II were pure by the criterion of polyacrylamide disc electrophoresis. With 200 μg of thymin I or II per gel there was a single major band stained with Coomassie blue in gels run at *p*H 8.9 or *p*H 4.3. Analysis of the terminal amino acids provided further evidence for purity. No residue could be identified at the N terminus of thymin I or II which was therefore considered blocked. Only lysine was identified at the C terminus of both thymin I and II (D. S. Schlesinger, G. Goldstein and H. D. Niall, in preparation).

Thus thymin I and thymin II seem to be very similar. They were closely associated during the various fractionation procedures and it was difficult to establish chromatographic conditions that would resolve them. The presence of at least some areas of common primary amino acid sequence was suggested by two sets of observations. Thymin I and thymin II were digested with trypsin and the tryptic peptides were mapped in two dimensions by chromatography and high voltage electrophoresis. Several peptides with similar positions were found in thymin I and thymin II, suggesting common sequences. Rabbit antisera raised against either thymin I or thymin II reacted with both and in two dimensional immunodiffusion on micro-Ouchterlony plates thymin I and thymin II produced a line of identity (Fig. 5). This again provided evidence that thymin I and thymin II had a common tertiary configuration being recognised by the antibodies and so probably had some common primary sequence.

Yet there is a consistent biochemical difference between thymin I and II as detected by ion exchange chromatography at *p*H 10.5 and polyacrylamide disc electrophoresis at *p*H 4.3. Although the evidence summarised above suggests that thymin I and II share extensive primary sequence it is still uncertain whether one represents a chemically modified form of the other or whether they are two distinct polypeptides

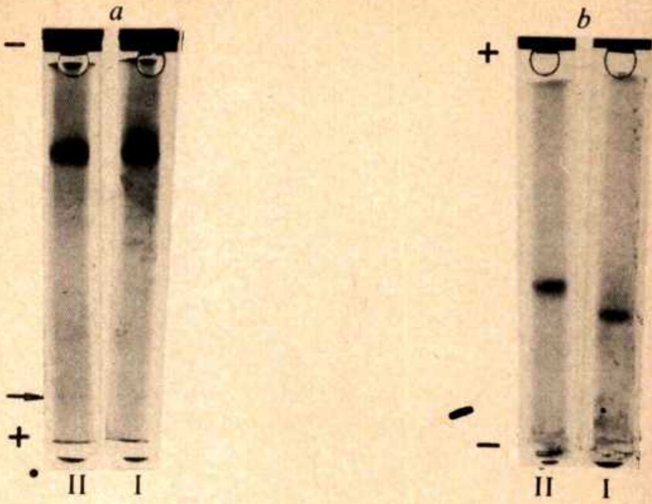

Fig. 4 Polyacrylamide gels from disc electrophoresis of 200 μg samples of thymin I and thymin II, *a* at *p*H 8.9 and *b* at *p*H 4.3. The gels were fixed with trichloroacetic acid and stained with Coomassie blue. One major band is present in each gel. Arrow indicates dye marker.

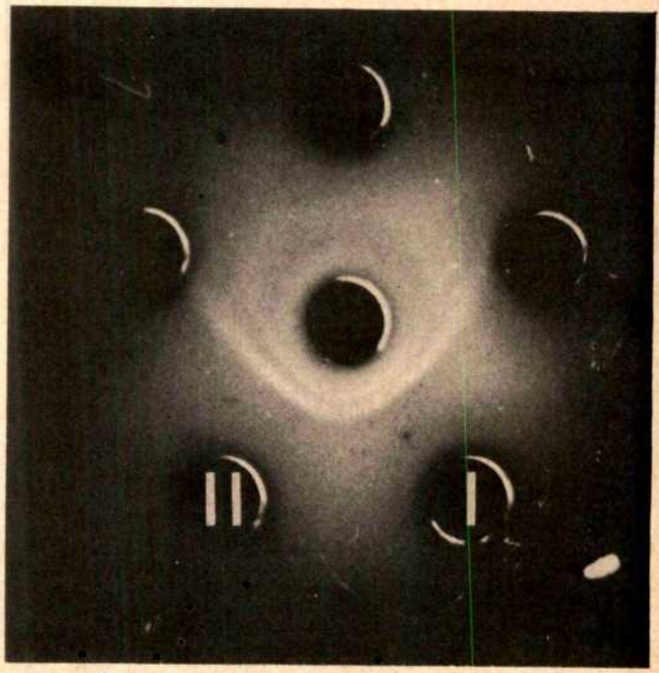

Fig. 5 Micro-Ouchterlony immunodiffusion with antiserum to thymin I in the centre well, thymin II (1 mg ml^{-1}) in the lower left well and thymin I (1 mg ml^{-1}) in the lower right well. After 24 h diffusion the plate was fixed in trichloroacetic acid and stained with Coomassie blue for photography.

with close sequence homology based on a common ancestral gene.

Biological Significance of Thymins

An interpretation of the findings in myasthenia gravis as suggestive of autoimmune thymitis[7,8] led to the development of a model of the disease in laboratory animals, experimental autoimmune thymitis[9-14]. Experimental analysis of this model implicated a substance released from the diseased thymus in the pathogenesis of the neuromuscular lesion[9,13,14] and experiments on thymectomised and thymus-grafted animals indicated that this substance was also secreted by the normal thymus[15]. This thymic substance affecting neuromuscular transmission was termed thymin.

The prime function of the thymus is the differentiation of lymphopoietic stem cells originating in the haemopoietic tissues to mature thymus-derived cells (T cells) capable of involvement in the immune response of the body[2,6]. Since this differentiating function is probably mediated by a hormone secreted by the epithelial cells of the thymus the finding of a hormone affecting neuromuscular transmission raises two possibilities. The thymus may secrete two separate hormone systems, one differentiating lymphopoietic stem cells, the other affecting neuromuscular transmission. Alternatively, by virtue of some similarity in the receptors of lymphopoietic stem cells and the neuromuscular synapse, the one hormone may affect both.

Purified thymin I, in subnanogram concentrations, caused a detectable neuromuscular lesion and also induced the differentiation of bone marrow cells *in vitro* in that they acquired antigens characteristic of intrathymic T cells (R. S. Basch and G. Goldstein, manuscript in preparation). Thus these findings suggest that thymin(s) are primarily hormone(s) of the thymus, inducing differentiation of lymphopoietic stem cells and that the effect on neuromuscular transmission is secondary and may be related to the presence of some receptor in the synaptic apparatus which is similar to that of the stem cells. Cholinergic receptors are present on both stem cells[21] and mature lymphocytes[22], and it is possible that the receptors of stem cells which induce differentiation to T cells may have evolved from such cholinergic receptors.

By this reasoning the neuromuscular effect of thymin is a chance one, rather than a primary physiological regulating function of the body. Nevertheless, the mode of action of thymin in producing neuromuscular block is of great interest. Although thymin results in a postsynaptic block in neuromuscular transmission[12] the evidence is that it does not combine directly with the classical acetylcholine receptor since it is inactive *in vitro*[19], causing neither acute blocking nor depolarisation, and it has an 18 h latent period *in vivo*, the effect then persisting for several days. These findings would suggest that thymin is affecting a regulatory mechanism in the neuromuscular synapse and thymin may be a valuable tool for probing such a mechanism of chronic modulation of synaptic conductivity.

This work was supported by the Irvington House Institute and grants from the National Institute of Neurological Diseases and Stroke of the US Public Health Service, the Muscular Dystrophy Associations of America and the Sackler Research Fund. Ronald King and Miriam Siegelman provided technical assistance. I am grateful for the advice and collaboration of Drs H. N. Niall, D. S. Schlesinger, R. S. Basch and M. E. Lamm.

Structure of Yeast Phosphoglycerate Kinase

T. N. BRYANT, H. C. WATSON & P. L. WENDELL

Molecular Enzymology Laboratory, Department of Biochemistry, University of Bristol, Bristol BS8 1TD

A 3.5 Å resolution electron density map of yeast phosphoglycerate kinase has been calculated from which a skeletal model of the enzyme's single polypeptide chain has been constructed. The position of the nucleotide substrate ADP when bound to the enzyme has been defined.

We recently reported the structure of yeast phosphoglycerate kinase (PGK) as seen at 5 Å resolution[1]. This work and that of Blake *et al.*[2], who have carried out similar crystallographic studies with horse muscle phosphoglycerate kinase, have shown that this monomeric enzyme is composed of two lobes connected by a waist region. A 3.5 Å resolution electron density map of the yeast enzyme has now been calculated, from which it is possible to follow the course of the polypeptide chain starting in one lobe and passing through the central waist to form the structure of the second lobe before returning to complete the structure of the first lobe.

The reaction catalysed by PGK is the first of the two ATP-forming reactions of the glycolytic pathway. By soaking crystals of the enzyme in solutions containing nucleotide substrates we have also located the position of a unique Mg-ADP binding site near the surface of one of the two lobes.

Structure Determination

Two single-site heavy atom derivatives of PGK were obtained by soaking crystals with mercuric acetate or sodium aurichloride respectively, as previously described[1]. X-ray intensity data to 3.5 Å resolution were collected from the native protein using a computer-controlled four-circle diffractometer. These 7,820 measurements were divided into sets on the basis of intensity, each set containing approximately one-tenth of the X-ray reflections. Data for each of the two derivatives were collected for the six sets of highest intensity, totalling 3,752 independent Bijvoet pairs. Scaling of derivative to native data and the refinement of heavy atom parameters were carried out separately for each set of reflections. Anomalous scattering data were included in refinement and phase calculation procedures. The mean figure of merit[3] for all measured reflections was 0.76. The electron density distribution of the native enzyme, calculated using centroid phases[4], was plotted on Cobex sheets, in sections of constant y on a scale of $10^8:1$. A molecular model was built using Nicholson model components (Labquip, Reading, England), which were fitted to the electron density using an optical comparator[5]. In the absence of sequence information, each amino acid residue was inserted as L-alanine.

Interpretation of Electron Density

For much of its length, the course of the polypeptide chain could be followed without difficulty, and density corresponding to the larger amino acid side chains was clearly visible. Helical regions of the polypeptide chain were also immediately apparent, as is shown in Fig. 1. Since the correct 'hand' of the protein had been determined using the anomalous scattering data[1], the polarity of the chain could be defined by noting the orientation of the side chains in helices and in some runs of extended chain. As expected at this resolution, the main chain carbonyl oxygens were not resolved from the rest of the main chain, so that the orientation of the peptide bonds could not be determined directly. The planar peptide groups were therefore adjusted to give the best fit to the main chain density, and to locate β-carbon atoms at side chain density where this was clearly indicated. At bends in the chain, it was sometimes impossible, in the absence of sequence information, to tell how much of the density was due to main chain and how much to side chain atoms, so that an amino acid may have been omitted or inserted in such places. Also, the close approach of several runs of chain makes it difficult to determine, by immediate inspection, the correct connection between strands entering and leaving two small inadequately resolved sections of the molecule. The correct interpretation must produce for the molecule as a whole a single, continuous polypeptide chain with each element of the secondary structure having the correct polarity. This criterion was used to resolve any ambiguity in difficult regions of the map.

Knots in the polypeptide chain would not be expected to arise during spontaneous folding of the protein, but might easily be produced in a model by misinterpretation of the electron density map. In this case it is possible to trace the entire course of the chain starting from the amino terminus without having to pass the growing carboxyl end through any loop of chain already produced. It must be emphasised, however, that, apart from any possible error in the X-ray measurements, the absence of sequence information and the possible existence of flexible sections of polypeptide chain make certainty of interpretation unattainable at this stage in our investigation. We nevertheless believe that the structural information now available may be of considerable use in providing a conceptual framework for those interested in the structure and mechanism of kinases.

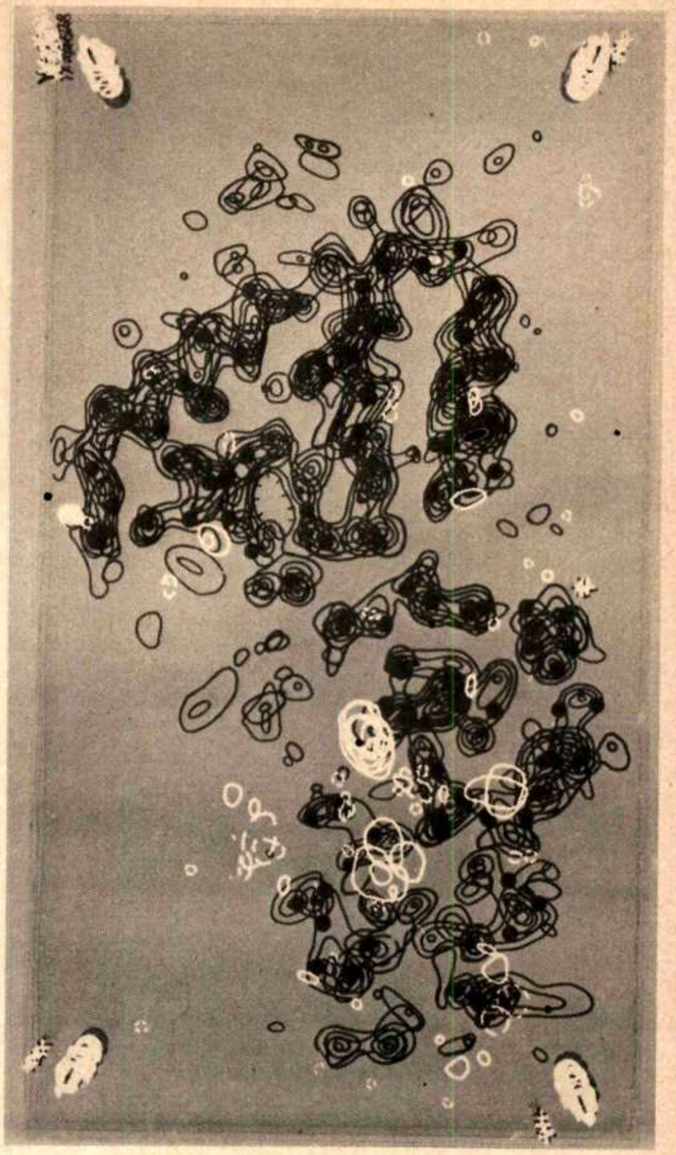

Fig. 1 Sections through the electron density map of PGK (black contours) with the difference electron density map of PGK+(Mn-ADP) minus PGK superimposed. Lowest black contour is at 0.35 e Å^{-3} followed at intervals of 0.15 e Å^{-3}. Broken white contours are negative, full ones positive. White contours are drawn at intervals of 0.06 e Å^{-3} with the zero contour omitted. The positions of α carbon atoms are marked with black disks. The axis of helix B2 lies in the plane of the sections and can be seen running from the top centre to middle left hand side of the map. Lobe B is above lobe A as illustrated. The peak assumed to be associated with the metal-phosphate end of the ADP molecule (peak 1) is the peak contoured in white nearest the centre of the map. The difference peak immediately below peak 1 is thought to represent the adenine portion of the ADP molecule. Other difference electron density peaks do not exceed one contour level on any one Fourier section.

The PGK Molecule

The separation of the monomeric PGK molecule into two lobes connected by a central waist region[1,2] is now confirmed. The polypeptide chain crosses twice between the two lobes, once in each direction. This means that both chain termini must occur in the same lobe, lobe A. The other lobe, lobe B, contains the yeast enzyme's single sulphydryl group, as judged from the positions of our two heavy atom sites[1].

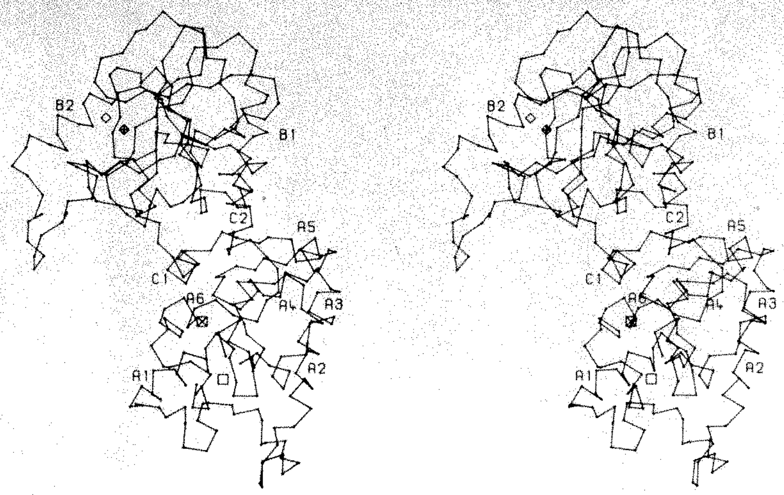

Fig. 2 Stereoscopic drawing of the PGK molecule viewed in the same orientation as the electron density map shown in Fig. 1. The positions of the α carbon atoms are marked so as to help the viewer follow the course of the main chain. The helical segments are labelled A1–A6, B1–B2, and C1–C2, to indicate the lobe or central waist region and numerical order of occurrence along the chain from the amino end. The positions of the two heavy atom sites are marked by open (Au) and crossed (Hg) diamonds respectively. The positions of the two significant difference Fourier peaks (see text) are shown with open (peak 2) and crossed (peak 1) squares respectively.

Of the total of 357 residues built into our model, 157 are in lobe A and 181 in lobe B, the remaining nineteen residues forming the connecting region between the two lobes.

Each of the two main chain connections between the lobes includes a short helical segment, designated C1 and C2. Inspection of the electron density map also shows five contact areas involving amino acid side chains which could be important in maintaining the two lobes in their relative orientations. On one side of the molecule, a residue near the carboxyterminal end of helix C1 (see stereo diagram) is in contact with a residue in helix A6. The amino terminal residue of helix C1 is in contact with another, non-helix, residue in lobe A, and the preceding residue is in contact with a non-helix residue in lobe B. At the other side of the molecule, two residues in helix C2, separated by a single amino acid, are in contact with residues in lobe A and lobe B respectively.

The molecule as a whole contains ten helices, six in lobe A, two in lobe B, and the two already referred to as forming part of the inter-lobal connection. Altogether some eighty-six residues, or one-quarter of the molecule, are involved in these helical segments, which vary in length from six to thirteen residues.

Although the existence of interchain hydrogen bonds cannot be established directly at this resolution, there are regions in each lobe where sections of extended polypeptide chain run sufficiently close together to suggest that a β pleated sheet is formed. These β pleated sheet regions tend to form the core of each lobe, and seem to be protected from the solvent by the helices, which all lie approximately tangential to, and form part of, the surface of the molecule. In lobe A, three strands running parallel in direction and sense form a plane between helices C2 and A3. Adjacent to this plane, the amino terminal part of the chain folds to form a compact double bend whose three short constituent sections lie close together in a plane between helices A6 and A2. These two possible regions of β pleated sheet also have a short common boundary whose adjacent chains run in opposite directions. In the other lobe, a twisted sheet is formed, between helices B1 and B2, by five chains, the middle one of which runs from the carboxy terminal end of helix B1 (the top of helix B1 as shown in the stereo diagram).

At two places in the molecule, for a distance of one amino acid residue, the main chain seems to pass through negligible electron density. In one further place there is a similar gap at the tip of a loop protruding into the external solvent. Although we have bridged this gap with a single amino acid, the conformation and position of this region would be consistent with the presence of a larger loop. Such a large flexible loop would not be revealed using X-ray diffraction techniques, and might help to explain the discrepancy between the 357 residues built into our model of the enzyme and the 420 residues calculated to be present using molecular weights determined by other physical methods[6,7]. We believe, however, that this discrepancy is such as to suggest that solution studies have led to overestimation of the molecular weight of PGK.

Structure and Reactivity

The heavy metal ligands used in the structure determination bind to the enzyme at two points 6 Å apart between two chains near the surface of lobe B. Although it is not possible at this stage in the investigation to indicate which of these two chains contains the molecule's single cysteine residue, it is quite clear that this residue is some 30 Å from the catalytically active site of the enzyme, as is shown in the stereo diagram. This is consistent with the finding that the cysteine residue is not essential for enzymic activity[7,8].

Substrate binding studies with yeast PGK are still at a preliminary stage. Changes in X-ray diffraction intensity have been observed for crystals soaked in the presence of adenosine[9], and of ADP with and without Mg^{2+} or Mn^{2+}, but not with 3-phosphoglycerate. Complete sets of 5 Å resolution X-ray diffraction data have been collected for the promising derivatives, and various combinations of difference electron density maps have been calculated. These maps show two consistent features, both positive, as is illustrated in Fig. 1, where the peaks associated with the PGK+(Mn–ADP)−PGK difference map are superimposed on equivalent sections of the normal electron density map. These peaks, designated peak 1 and peak 2, are shown in the stereo diagram with crossed and open squares respectively. Both peaks normally seem to be at least three times the general error level and are easily the strongest features in the calculations. In difference electron density maps between PGK+(Mg–ADP or Mn–ADP) and PGK alone, peak 1 is about 50% stronger than peak 2, whilst in the PGK+(Mn–ADP)−PGK+(Mg–ADP) difference map peak 1 is three times as strong as peak 2. These results suggest that peak 1 represents the phosphate-metal end of the ADP molecule whilst peak 2 represents the adenine portion. The two peaks are positioned in space in such a way that an ADP molecule can be built into the observed density which is fully consistent with this interpretation; the nucleotide substrate making very reasonable contacts with the protein without the need for any obvious change in conformation. Presumably the sugar moiety is not seen in the difference maps because it displaces some other molecule or group of molecules when the enzyme, in the crystal, binds ADP.

The picture of the PGK molecule which is now emerging thus focuses our attention on one region in particular. This is the 20 Å-deep wedge-shaped space between the two lobes, with helix C1 at its apex, which is on the same side of the molecule as the single sulphydryl group. This area contains, besides several points of inter-lobal contact, the nucleotide binding site. One may therefore expect that the residues involved in the transfer of the bioenergetically important phosphate group will be found in this region. We also note that the main structural features of the nucleotide binding lobe are similar to those which have been shown to surround the NAD binding site of several dehydrogenases[10-12]. A detailed comparison of the kinase and dehydrogenase binding sites must await extension of the present investigation. From the evidence now available, however, it seems probable that evolution has produced a general method for binding nucleotide substrates, and that the architecture of this binding site has been conserved for enzymes requiring such a function, including kinases.

Results comparable to those described here for yeast PGK have been obtained by Dr Blake and his colleagues at Oxford for the horse muscle enzyme. We thank the Oxford group for showing us the results of their work before publication. We also thank the Science Research Council for supporting our laboratory and for the award of a research studentship to one of us (T. N. B.).

Production of Superheavy Nuclei by Multiple Capture of Neutrons

W. M. HOWARD* & J. R. NIX
Los Alamos Scientific Laboratory, University of California, Los Alamos, New Mexico 87544

A new calculation of fission barriers and neutron separation energies for heavy neutron-rich nuclei indicates that it is unlikely that superheavy nuclei can be produced either in the astrophysical r process or in man-made nuclear explosions.

PREDICTION of the possible existence of superheavy nuclei has led to attempts to produce them in the laboratory and to searches for them in nature. Calculations of the nuclear properties of such nuclei[1-4] have predicted half-lives as long as 10^9 yr. Thus, if these nuclei are produced in astrophysical environments, they should be detectable on the Earth and in cosmic rays impinging on the Earth. So far efforts to produce them in the laboratory or to find them in nature have failed.

There has been much interest in whether superheavy nuclei can be produced in the astrophysical r process, which is known to produce many of the naturally occurring neutron-rich nuclei between germanium and bismuth and all of the naturally occurring nuclei heavier than bismuth. The r process, occurring during some catastrophic supernova event, is the capture of neutrons on a time scale much faster than beta decay. Different studies have led to conflicting conclusions[5-15] as to whether superheavy nuclei can be produced by the r process. The important question is where neutron-induced fission terminates the r-process path in the region of heavy neutron-rich nuclei. This termination depends on how rapidly the effective surface tension of a nucleus decreases with increasing neutron excess and on the extra stability against fission gained from single particle effects near the neutron closed shell at $N=184$. The treatment of these two effects depends first on an extrapolation of the surface tension of nuclei along the valley of beta stability to nuclei far to the neutron-rich side of the valley of beta stability. Second, it depends on an extrapolation of the additional binding at known closed shells to the predicted closed shell at $N=184$. The various treatments of these two effects have resulted in the conflicting conclusions.

In this paper, we re-examine the question of the formation of superheavy nuclei by the r process, as well as their possible production in thermonuclear explosions, either of the conventional type or of the multistep type proposed by Meldner[16]. Figure 1 illustrates the path each of these processes would follow in the neutron-rich region in their approach to the island of superheavy nuclei.

Nuclear Potential Energy of Deformation

Since neutron-induced fission plays the critical role in terminating these processes, we calculate the fission barriers and neutron separation energies for a broad region of heavy neutron-rich nuclei, outlined by the dashed lines in Fig. 1. We use an improved version of the macroscopic–microscopic method, in which the smooth trends of the nuclear potential energy of deformation are calculated from a macroscopic model and the local fluctuations from a microscopic model. This method is described completely in recent review articles[17-21].

We pay special attention to the effective nuclear surface tension by using the droplet model of Myers and Swiatecki[22] for the macroscopic energy. This model takes into account higher order terms in $A^{-1/3}$ and in $[(N-Z)/A]^2$ than are retained in the usual liquid drop model, where A is the mass number and $(N-Z)/A$ is the relative neutron excess. To calculate the microscopic corrections to the energy we use a

---

[*] Present address: Department of Astronomy, University of Illinois, Urbana, Illinois 61801.

realistic diffuse surface single particle potential[3,4]. The single particle potential parameters are obtained from statistical calculations[23] and from adjustments to reproduce experimental single-particle levels in heavy deformed nuclei[21]. The approach that we follow here reproduces experimental fission barriers in the actinide region and nuclear ground state masses[21] to within an accuracy of about 1 MeV and is consistent with information from conventional nuclear explosions in the neutron-rich region[24].

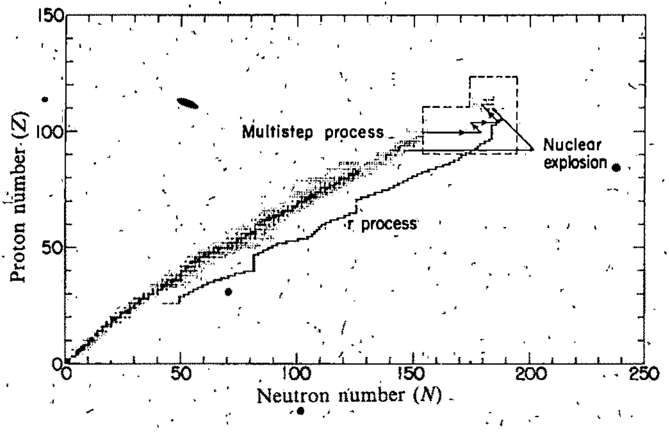

Fig. 1 Plot of known and predicted nuclei as a function of the neutron number N and proton number Z. The heaviest points represent stable nuclei, the medium size points nuclei with halflives greater than one year, and the lightest points nuclei with halflives less than one year. Nuclei with predicted halflives greater than about 5 min are included in the island of superheavy nuclei. The dashed lines outline the region of nuclei where we calculated fission barriers and nuclear ground state masses. Three possible ways to reach the island of superheavy nuclei by the multiple capture of neutrons are illustrated.

The neutron separation energies are calculated from ground state masses that are determined by minimising the potential energy with respect to the nuclear quadrupole moment Q_2 and hexadecapole moment Q_4. The fission barriers are calculated for a prescribed sequence of nuclear shapes relevant to the fission process. These details are discussed elsewhere.

Effective Surface Tension and Neutron Excess

In the liquid drop model for the macroscopic energy, the surface energy of a spherical nucleus is given by

$$E_s^{(0)} = a_s[1-\kappa((N-Z)/A)^2]A^{2/3} \quad (1)$$

where a_s is the surface energy constant and κ is the surface asymmetry constant. For a large value of κ, the effective surface tension decreases rapidly with increasing neutron excess, which results in decreased barrier heights for heavy neutron-rich nuclei. In the liquid drop model of Myers and Swiatecki[25] the surface asymmetry constant was assumed equal to the volume asymmetry constant, or to the value $\kappa = 1.7826$.

In the droplet model the shape dependence of the potential energy is more complicated than in the liquid drop model, and the constant κ no longer enters. But by neglecting the relatively small influence of some of the new shape-dependent energies, the more complicated dependence of the droplet model on the surface energy can be described[26] approximately in terms of an effective value of κ. Unlike in the liquid drop model, this effective value of κ depends on the mass number and the nuclear shape.

With the droplet model parameters of Myers and Swiatecki[22], we obtain $\kappa_{eff} = 2.8$ for the neutron-rich nucleus ^{280}Pu. Thus the effective surface tension decreases much more rapidly with neutron excess than in that liquid drop model. A recent determination of the constants of a truncated droplet model that reproduces both experimental ground state masses and fission barrier heights to within an accuracy of 1 MeV yields a value for ^{280}Pu of $\kappa_{eff} \approx 3.5$ (W. M. H. and P. A. Seeger, in preparation).

Fission-Barrier Heights

Figure 2 is a contour plot of the calculated fission-barrier height for even nuclei. We include a zero-point energy of 0.5 MeV for motion in the fission direction. Notice the large barriers ($\approx$10 MeV high) for nuclei in the superheavy region ($N \approx 184$, $Z \approx 114$). The barriers for these superheavy nuclei are similar to those that others calculate with a diffuse surface potential[3,4,18,20].

The barrier heights for nuclei in the region $176 \lesssim N \lesssim 192$ are largely the result of single particle effects because the macroscopic energy contribution has almost disappeared due to the large effective surface-asymmetry constant. Notice the pronounced enhancement of barrier heights for nuclei with neutron numbers near $N = 184$. In the broad region of nuclei $162 \lesssim N \lesssim 178$, $92 \lesssim Z \lesssim 106$ with relatively low fission barriers the capture of a neutron by these nuclei would lead to disastrous neutron-induced fission.

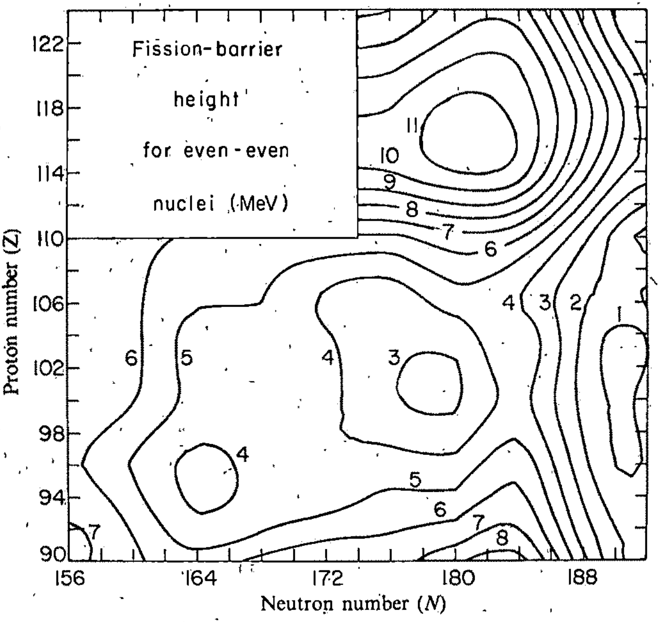

Fig. 2 Contour plot of the calculated fission-barrier height as a function of neutron number N and proton number Z for even nuclei. These fission barriers are calculated with droplet model constants that optimally reproduce nuclear ground state masses and fission barrier heights.

In order to study the sensitivity of the calculated barrier heights to the parameters of the droplet model, we have repeated the fission barrier calculations with two different sets of droplet model constants (W. D. Myers, private communication). These two sets of constants both give a standard deviation between the experimental and calculated ground state masses and fission barrier heights that is 10% larger than the optimum value. The results for these two different sets of droplet model constants are presented in contour plots in Figs 3 and 4. The constants used in the calculation in Fig. 3 yield an effective surface-asymmetry constant for ^{280}Pu of

$\kappa_{eff}=2.6$, while the constants used in the calculation in Fig. 4 yield $\kappa_{eff}=3.3$. As expected, the fission-barrier heights near the neutron closed shell at $N=184$ are almost independent of the droplet model parameters. The same microscopic corrections have been used for all of the calculations. In our consideration of the sequence of shapes for fission, we have not taken into account mass-asymmetric or axially asymmetric distortions. For some nuclei these effects could lower the calculated barriers by a few MeV.

Neutron Separation Energies

Figure 5 is a contour plot of the calculated neutron separation energy for even nuclei. The neutron separation energies decrease monotonically for increasing neutron excess. For a given determination of the neutron separation energy for neutron-rich nuclei, the r-process path can be determined approximately without carrying out a full r process calculation. Because it is a process in nuclear statistical equilibrium, it follows approximately a line of constant neutron separation energy, whose value we determine to be $B_n=3\pm1$ MeV for even nuclei.

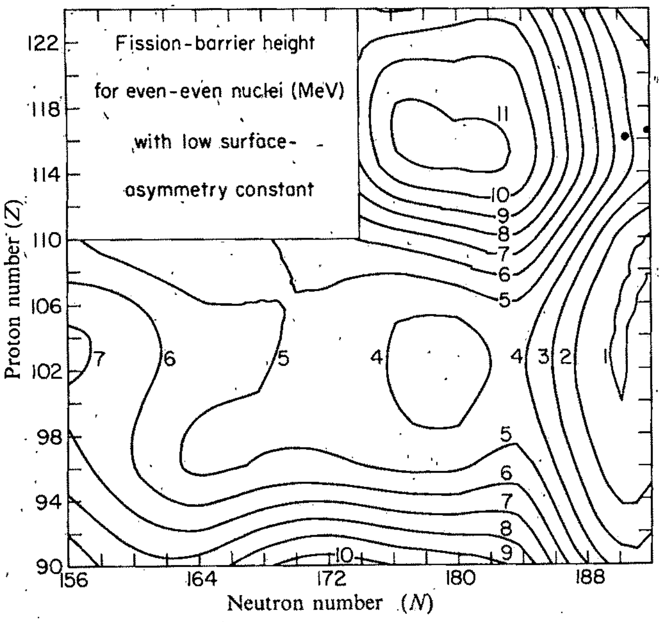

Fig. 3 Analogous to Fig. 2, except calculated with droplet model constants for which the effective surface asymmetry constant is lower. The error in the calculated ground state masses and fission barrier heights is 10% larger with these constants than with those used in Fig. 2.

Termination of Multiple Neutron-capture Processes

Figure 6 presents the essence of our results. When a nucleus captures a thermal neutron, it is excited to an energy equal to its neutron separation energy. When this energy is above the fission barrier height, then the nucleus will undergo neutron-induced fission at a much more rapid rate than the other available decay modes. Figure 6 is a contour plot of the difference between the fission barrier height and the neutron separation energy for even nuclei. From a study of Figs 5 and 6, we find the neutron-induced fission cutoff for the r process to be at $Z=96$ and $N=186$. Since the fission barrier heights in this region are almost independent of the macroscopic energy contributions, this cutoff is strongly dependent on the single-particle effects near the closed shell at $N=184$.

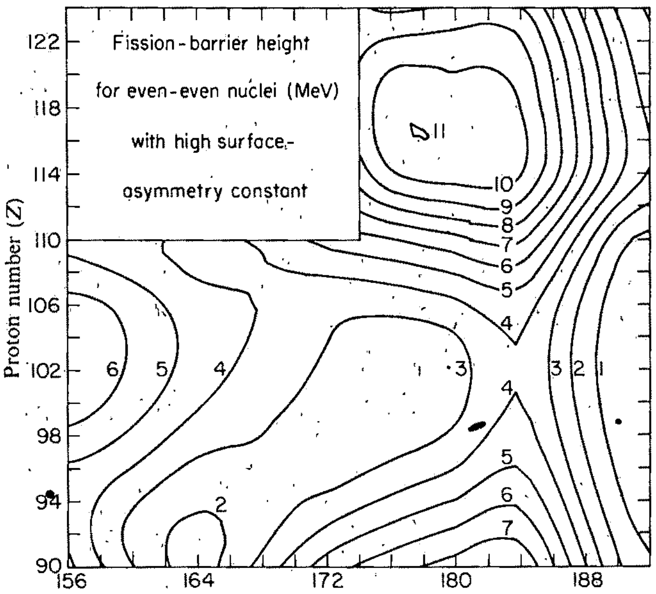

Fig. 4 Analogous to Fig. 2, except calculated with droplet model constants for which the effective surface asymmetry constant is higher. The error in the calculated ground state masses and fission barrier heights is 10% larger with these constants than with those used in Fig. 2.

Thus, we predict that nuclei with mass number $A=281$ will be the last to survive in the r process before neutron-induced fission terminates the path. According to the results of ref. 4, nuclei with mass number 281 would spontaneously fission with halflives of the order of 1 s after a few beta decays. In order for superheavy nuclei to be observed in cosmic rays, their halflives would need to be at least 10^6 yr. This would require the production of nuclei with mass number $A\gtrsim291$, which is 10 mass units higher than the heaviest yield that we predict.

Schramm and Fiset[13] suggest that a small fraction of the material at $N=184$ could climb along this closed shell during

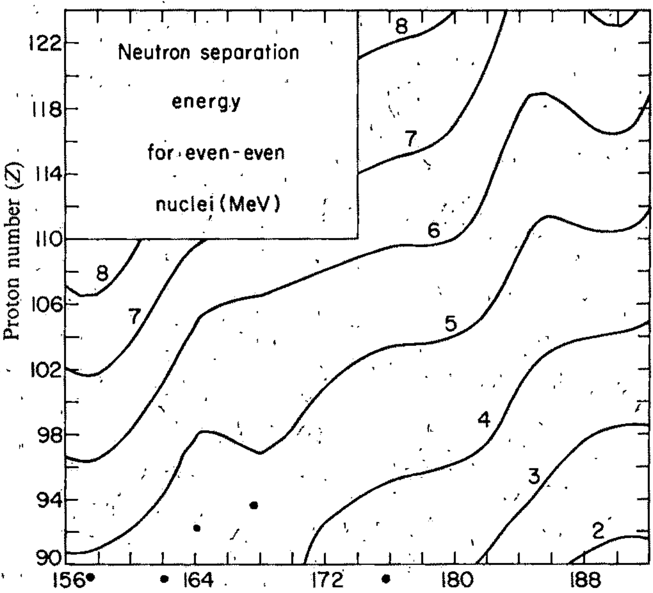

Fig. 5 Contour plot of the calculated neutron separation energy as a function of neutron number N and proton number Z for even nuclei.

a weak freeze out of the r process neutron flux and thereby reach the superheavy island. But as seen in Fig. 6, such nuclei would reach the 'cape' close to $Z=104$ and suffer neutron-induced fission before reaching the superheavy island.

Conventional nuclear explosions yield neutron exposures similar to those in the astrophysical r process; however, the time duration is so short ($\Delta t \lesssim 10^{-6}$ s) that there is no time for beta decays during the neutron-capture process. The thermal photon temperature is much less than in the r process. The neutron captures therefore proceed to a lower neutron separation energy, which extends into a more neutron-rich region. In nuclear explosions to date, targets of various actinide nuclei have been irradiated with intense neutron sources. Independent of the target used or the intensity of the neutron irradiation, the heaviest nucleus recovered from the debris[27] has been ^{257}Fm.

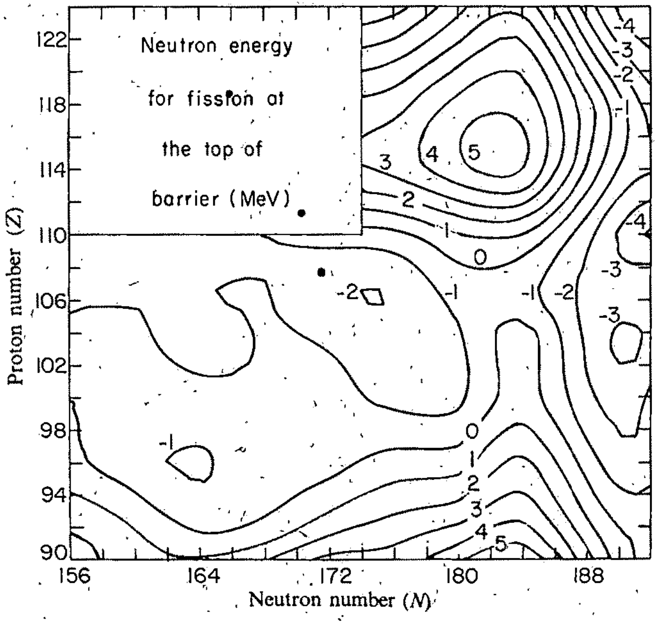

Fig. 6 Contour plot of the difference between the fission barrier height and the neutron separation energy for even nuclei.

We can understand this failure to produce heavier nuclei in terms of our results. From Fig. 6 we see that neutron-induced fission terminates the neutron capture chain on the U isotopes at mass number $A=256$. Actually, neutron-induced fission should occur somewhat before this because we overestimate the barrier for U isotopes in this region by 1 or 2 MeV by not including mass-asymmetric distortions. Thus, we conclude that conventional nuclear explosions have even less hope for producing superheavy nuclei than the r process.

The failure of conventional nuclear explosions to produce superheavy nuclei has led Meldner[16] to propose a multistep explosive process that would allow beta decays between subsequent explosions. But his process seems fraught with the same difficulties encountered in the r process and in conventional nuclear explosions. Certainly odd-mass capture chains would have to be utilised as well as a target lighter than Th to avoid initial termination of the process by neutron-induced fission. It would then be required that beta decay lead to a region of stability against neutron-induced fission before the next neutron burst.

Meldner would like to take advantage of neutron capture along odd-proton chains where the fission barriers could be enhanced relative to the barrier heights of even nuclei. In the actinide region the spontaneous-fission halflives of odd-particle nuclei are systematically about 10^3 times as long as those of neighbouring even nuclei[28]. These hindrances arise from an increase either in the height of the barrier or in the inertia (or in both). If this hindrance factor is assumed to arise only from an increase in the barrier height, then the barriers for odd-particle nuclei are raised by about 0.5 MeV relative to those for even nuclei[1].

An examination of Fig. 6 reveals that after an initial neutron burst and subsequent beta decay into $162 \lesssim N \lesssim 178, 92 \lesssim Z \lesssim 106$, the nuclei would be in a region where a second neutron burst would initiate neutron-induced fission. This conclusion also applies for odd-proton capture chains. But as we have seen, the relatively strong dependence of the fission-barrier heights in the region of $162 \lesssim N \lesssim 178$, $92 \lesssim Z \lesssim 106$ on the value of the effective surface-asymmetry constant makes this conclusion somewhat uncertain.

To summarise, we have used an improved version of the macroscopic–microscopic method to calculate fission barriers and neutron separation energies for a broad region of heavy neutron-rich nuclei. On the basis of these calculations we conclude that neutron-induced fission terminates the three possible multiple-neutron-capture processes well before the superheavy island is reached.

We thank G. A. Cowan, S. E. Koonin, H. W. Meldner, P. Möller, W. D. Myers, S. G. Nilsson, D. N. Schramm, P. A. Seeger and A. J. Sierk for discussions. This work was performed under the auspices of the US Atomic Energy Commission.

Model for Cygnus X-3

CYGNUS X-3 has been identified[1] with the infrared object found by Becklin *et al.*[2] to be within ±2″ of the radio position: the infrared object is found to vary in intensity with the same period as and in phase with the X-ray object. The infrared flux (2.2 μm) varies smoothly by about 15% whereas the X-ray intensity varies by a factor ~3. Cyg X-3 is unique among other regularly varying sources in that the X-ray light curve is smooth and roughly sinusoidal[3], displaying no sudden intensity variations indicative of an eclipse of a compact X-ray source by a larger object (for example, a companion star). We show that nevertheless Cyg X-3 can be interpreted by means of the 'standard model' for galactic X-ray sources in terms of mass loss from a large companion star and accretion onto a compact object.

We assume throughout that the 4.8 h period is due to orbital motion. Kepler's Law (assuming a circular orbit) yields

$$D \approx 10^{11}\ (M/M_\odot)^{\frac{1}{3}}\ \mathrm{cm} \qquad (1)$$

where D is the distance between the two stars and M is the total mass of the system. If this is also the size of the infrared object (or an upper limit to it) we can obtain a lower limit to the brightness temperature at 2.2 μm (see ref. 1)

$$T_B \gtrsim 3\times10^6\ (M/M_\odot)^{-\frac{2}{3}}(d/10\ \mathrm{kpc})^{\frac{1}{2}}\ \mathrm{K} \qquad (2)$$

where d is the distance to the source. From radio data[6] we know that $d \gtrsim 10$ kpc.

If the bulk of the infrared flux is due to radiation from the surface of an ordinary star we need[4] $M \gtrsim 70\ M_\odot$. In this case the 2.2 μm variation cannot be due to tidal effects—this would give two infrared minima per X-ray period—and the most likely explanation would be that it is a reflection effect. For a 15% variation in the infrared, the X-ray source must give a variation in the energy flux over the stellar surface of nearly a factor of two. This is possible, but, if so, the reflection effect could easily give rise to all the infrared emission, obviating the need for such a massive system. I shall therefore assume the standard model: X rays originate from a compact object (I show below how the light curve may be produced) and the infrared flux is due to heating of the companion star (or its extensive atmosphere or wind) by the X-ray star.

The observed mean X-ray luminosity in the 2 to 6 keV range is[5]

$$L_X \approx 3\times10^{37}\ (d/10\ \mathrm{kpc})^2\ \mathrm{erg\ s^{-1}} \qquad (3)$$

If the infrared emission comes from the Rayleigh-Jeans tail of radiation from an optically thin source emitted by a gas at temperature T_B, the total luminosity of the gas is given by

$$L_g \gtrsim 4\times10^2\ L_{IR}(M/M_\odot)^{-\frac{2}{3}} \qquad (4)$$

where L_{IR} is the luminosity at 2.2 μm. Using the dereddened flux at 2.2 μm (ref. 1)

$$L_X \approx 4\times10\ L_{IR} \qquad (5)$$

R373

Thus the total X-ray luminosity must be given by $L_{XT} = f\ L_X$ where

$$f \gtrsim 10(4\pi/\Omega)(1-\alpha)^{-1}(M/M_\odot)^{-\frac{2}{3}} \qquad (6)$$

Ω is the solid angle subtended by the gas from the X-ray source and α is the albedo. Thus to power the infrared source we require a total X-ray luminosity in excess of that observed in the 2 to 6 keV range. That is, the bulk of the X-ray luminosity is emitted either above 6 keV or below the low energy cut-off at about 3 keV. This is similar to what is required in the system Her X-1/HZ Her (ref. 7 and Y. Avni *et al.*, to be published). If the inclination of the orbit i is moderate (say $30° \lesssim i \lesssim 60°$), variation in aspect of the gas and of the amount of gas visible can easily produce the required smooth 15% variation.

I now outline a possible model for producing the X-ray light curve. I suggest that the smooth variation of the X-ray luminosity is produced by a gradual and partial eclipse of the (compact) X-ray object by a stellar wind emanating from its larger companion. This same wind can also give rise to the mass transfer required to power the X-ray source. The 2 to 6 keV spectrum has a variable low energy cut-off, but this variation does not appear to be correlated with the 4.8 h period (P. Sanford, private communication). Thus, and also for simplicity, I assume that the main opacity in the wind is electron scattering. For moderate inclination i we shall see that the electron scattering optical depth τ_{es} can vary by order unity over the orbital period. Thus if $\tau_{es} \sim 1$, the luminosity of the compact source will seem to vary by ~3. If, however, absorption is unimportant everywhere in the wind, backscattering of X rays would provide a diffuse background X-ray luminosity comparable to that of the compact object. So to obtain the required X-ray variation, we need absorption to be important but not dominant.

For the sake of argument I limit discussion to a specific model of the wind. I assume (see ref. 7) that the wind is emitted by the star in a spherically symmetric fashion at about the escape velocity, and that the parts of the wind where absorption and scattering take place are dynamically unaffected by the presence of the X-ray source. Conservation of mass implies that the wind density falls off as the inverse square of the distance from the star. The electron scattering optical depth is given as a function of θ, the angle between the line of sight and the axis of symmetry of the system by

$$\tau_{es} = 0.2\times10^{-24}\ NDg(\theta) \qquad (7)$$

where

$$g(\theta) = (\pi-\theta)/\sin\theta \qquad (8)$$

and N is the number density at distance D from the large star. The unscattered X-ray flux seen at infinity, L_U, is given in terms of the source luminosity L_S by

$$L_U = L_S \exp\{-\tau_{es}(\theta)\} \qquad (9)$$

and the X-ray light curves obtained using this are shown in Fig. 1 for various values of the inclination. For each value of i, $\tau_{es}(\pi/2)$ has been chosen such that the overall luminosity variation is by about a factor of three. Note the similarity between these curves and the actual light curve of Cyg X-3.

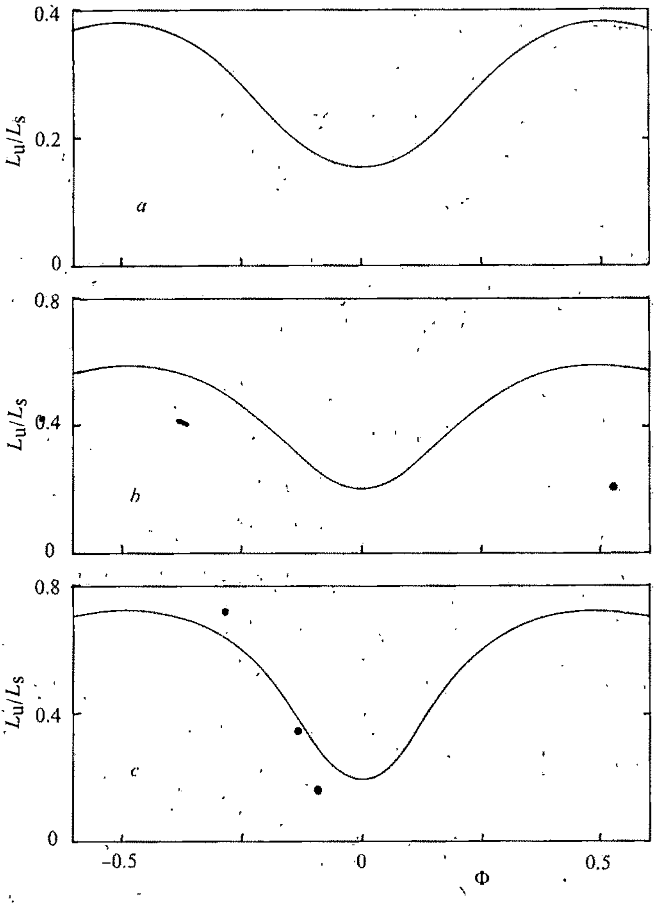

Fig. 1 The fraction of X-ray flux that reaches the observer unscattered, L_U/L_S, is plotted against binary phase Φ for various values of the inclination i and the optical depth to electron scattering $\tau_{es}(\pi/2)$. *a*, $i=30°$, $\tau_{es}(\pi/2)=1.25$; *b*, $i=45°$, $\tau_{es}(\pi/2)=0.75$; *c*, $i=60°$, $\tau_{es}(\pi/2)=0.5$. For each i, the value of $\tau_{es}(\pi/2)$ has been chosen to give an overall variation of about a factor of three.

I argued earlier that absorption in the wind must be important but not dominant. That is, we must have

$$\lambda = F/(4\pi D^3 N^2 a) \simeq 1 \qquad (10)$$

where F is the ionising photon flux and a the effective recombination coefficient (see ref. 7 for a fuller discussion). Using $a \sim 3\times10^{-10}\,.\,T^{-\frac{3}{4}}$, we obtain

$$N \approx 10^{13}(M/M_{\odot})^{-\frac{1}{2}} L_{38}^{\frac{1}{2}} T_6^{\frac{3}{8}}\ \mathrm{cm}^{-3} \qquad (11)$$

where L_{38} is the X-ray luminosity in units of 10^{38} erg s^{-1}, T_6 is the temperature of the wind in units of 10^6 K and I have assumed the typical ionising photon to have an energy of 5 keV. This density implies

$$\tau_{es}(\pi/2) \approx 0.5(M/M_{\odot})^{-\frac{1}{6}} L_{38}^{\frac{1}{2}} T_6^{\frac{3}{8}} \qquad (12)$$

in rough agreement with previous estimates. This density also indicates that the overall mass loss rate from the large star must be

$$\dot{M}_1 \approx 10^{-6}(M/M_{\odot})^{\frac{1}{2}}(M_1/M) L_{38}^{\frac{1}{2}} T_6^{\frac{3}{8}}\ M_{\odot}\ \mathrm{yr}^{-1} \qquad (13)$$

where M_1 is the mass of the large star. So for this model we expect the 4.8 h period to change on a time scale of ~10^6 yr.

I note also that inhomogeneities in the wind and variations of the wind strength can lead to irregular variations in the low energy cut-off. Absorption is more important near X-ray minimum, and so the X-ray curves calculated on the basis of electron scattering alone will be distorted downwards near minimum. Thus the variation will be less pronounced at high energies than at low energies where absorption is more important. I note in passing that a mass loss rate of ~$10^{-3}\ M_{\odot}$ yr^{-1} of the kind suggested by van den Heuvel and De Loore for the source Cen X-3 (ref. 8) would entirely extinguish any X-ray flux from the compact object. Unless the velocity of the wind exceeds the escape velocity from the system by several orders of magnitude, the wind density required would imply $\tau_{es}(\pi/2) \gg 1$ and $\lambda \ll 1$.

This model predicts that a large fraction of the total X-ray luminosity is absorbed in the stellar wind. Basko and Sunyaev[9] show that for stars with a high mass loss rate most of the energy is absorbed by gas with $T \sim 10^6$ K (comparable to T_B). Most of this energy is re-radiated as ultraviolet and as soft X rays from a region whose size is comparable to that of the system. This confirms that the spectrum from the gas will be flat out to wavelengths as long as 2.2 µm, before turning over to Rayleigh-Jeans at longer wavelengths. If this soft X-ray flux were visible we expect it to vary in a similar way to the infrared flux. The hard X-ray flux varies by a much greater amount and so cannot come from the same region. Also, the optical flux predicted here is much less than that expected from a straightforward extrapolation of the infrared flux along the Rayleigh-Jeans curve, as would be the case if the bulk of the infrared flux came from the stellar surface. Finally, I stress again the uniqueness of the system Cyg X-3 and, in a sense, the uniqueness of this model. For the parameters of Cyg X-3 we can have $\tau_{es} \sim 1$ and $\lambda \sim 1$. If the system were larger or smaller we could not satisfy both of these for any wind density, since $\lambda\tau_{es}^2 \propto D^{-1}$, independent of N.

I thank Professor Martin Rees for discussions and Dr P. Sanford for communicating results prior to publication. I acknowledge a Science Research Council studentship.

Close Pairs of QSOs

IT has recently been argued[1,2] that the observation of close pairs of QSOs with very different redshifts provides support for non-cosmological explanations of the redshifts. We show in this note that the pairs observed so far may be comfortably explained as random coincidences and that the small probabilities that are often quoted depend on the use of *a posteriori* statistics.

The expected number of close pairs of QSOs is given by

$$\mathscr{N} = N_Q\ (\pi R^2)\ \rho(\leq m) \qquad (1)$$

where N_Q is the total number of QSOs whose redshifts have been determined, R (in arc s) is the 'region of interest' around any given QSO (or the maximum allowable separation for 'close' pairs), and $\rho(\leq m)$ is the total number of QSOs per square arc s down to a limiting magnitude m. Equation (1) may be rewritten inserting typical numbers[3], as

$$\mathcal{N}(R,m) \approx 7 \times 10^{-2}\ (N_Q/1{,}000)\ (R/10'')^2\ 10^{0.6(m_v-19)} \qquad (1')$$

It should be noted that the typical *a posteriori* probabilities, calculated with the aid of equation (1), for the chance occurrence of a pair of close QSOs are not terribly small; they roughly correspond to 3 σ events.

We recall the basic observational facts. There are now two known 'close' pairs of QSOs: Ton155, 156 (ref. 1) with a separation of $35''$, redshifts $z = 1.7$ and 0.55, and $m_v \approx 16.0$ and 16.6 mag; and 1548+115 a, b (ref. 2) with a separation of $5''$, redshifts of $z = 0.44$ and 1.9, and $m_v \simeq 17$ and 19 mag.

We note that the initial observation[1] of a close pair of QSOs, Ton155 and Ton156, could not be regarded by itself as statistically significant because the typical correlation-separation previously discussed[4] was several degrees (yielding for typical values of R and m in equation (1) values of $\mathcal{N} \gg 1$). But we might legitimately have used the initial observation to define an hypothesis to be tested, for example: QSOs brighter than $m_v = 17$ mag have a much higher chance of appearing close together, $R \leq 35''$, than would be expected from a random distribution. On the basis of this hypothesis, the subsequent observation of the close pair 4C11.50 a, b (= 1548 and 115 a, b) is not remarkable. First, m_v (1548 and 115 b) is ~ 19 mag, much fainter than either of the Ton objects, so that the above defined hypothesis does not even cover this case. If we extend the limiting magnitude down to 19.4 mag (so it comfortably covers the observed pair 4C11.50 a, b), then $P(35'', 19.4) \sim 0.5$ compared with the observed value of 2. Actually even this calculation underestimates the expected number of pairs on the cosmological hypothesis. There is no *a priori* reason to suppose that $m = 19$ mag or even $m = 19.4$ mag is especially significant and one will always get unrealistically small probabilities for events if one calculates after the fact the chance expectation using the already observed parameters to define the experiment. In fact, experience shows that *a posteriori* probabilities at the 1% level are not particularly uncommon for random events; but of course *a posteriori* probabilities at the 10^{-6} or 10^{-10} level still are.

It is interesting to estimate the number of close QSO pairs that one would expect *a priori* on the cosmological hypothesis down to the limiting magnitude (~ 21 mag) of the blue Sky Survey (on which most of the identifications are made). For a total of 10^{-3} QSOs with known redshifts (perhaps a reasonable expectation for the next several years) and a maximum separation of $10''$, we expect one or possibly a few pairs. If we enlarge the maximum separation to $30''$ we expect about ten close pairs. These estimates are of course uncertain by at least a factor of three because we do not yet have an accurate determination of the QSO spatial density at faint magnitudes. Nevertheless, close pairs of QSOs should be rather common when it becomes standard practice to measure redshifts for all faint stars near accurate radio source positions.

Response of Dayside Thermosphere to an Intense Geomagnetic Storm

INCREASES in the density of the neutral thermosphere associated with geomagnetic activity were first noted by Jacchia[1]. Although the thermosphere will not be in equilibrium, and acceleration by electrodynamic forces may be involved, on balance the increased density must reflect additional heating. Further studies[2-4] by orbital drag analysis from observations of artificial Earth satellites have led to a complex and somewhat confusing picture. The heating seems to be slightly greater[3,4] at high latitudes and, for larger disturbances, sometimes much greater[2,3]. Also, the heating seems to be slightly greater[3,4] on the nightside, but possibly with the opposite trend[3] for larger disturbances ($K_p > 5$). Jacchia *et al.*[3] also found that the time delay between the peak of the storm, as measured by the planetary 3-h indices K_p or a_p, and the maximum response was a little shorter at high latitudes; on the other hand Roemer[4] concluded that the time delay was independent of latitude, height or local time.

The low g accelerometer calibration system (LOGACS) experiment[5,6] carried on an attitude-controlled Agena vehicle launched by the United States Air Force on May 22, 1967, provided a unique opportunity to determine the response to an intense storm. As the histogram in Fig. 1 shows, the planetary 3-h geomagnetic index, a_p, started to increase on May 25, reached a peak of 236, then fell slightly before increasing to the conventional maximum of 400 for two successive 3-h periods. Figure 1 also gives the hourly equatorial Dst index[7] which is based only on the horizontal H components at low latitude observatories and effectively measures the strength of the ring current during the storm.

The LOGACS accelerometer provided values of atmospheric density with an estimated accuracy better than 10% and a time resolution of 1 s, although at much longer intervals. Using these values, DeVries[5,6] found that the density in the (northern) nightside auroral regions increased with the onset of geomagnetic activity whereas the density in the (northern) dayside auroral regions initially decreased. The density over the rest of the Earth apparently reached a maximum with a time delay ranging from near zero in the nightside auroral regions to about 6 h at the dayside equator. DeVries concluded that most of the energy was injected in the nightside auroral regions probably, he suggested, by Joule heating[8] at or below 150 km, and transported over the rest of the Earth by convective circulation and atmospheric gravity waves.

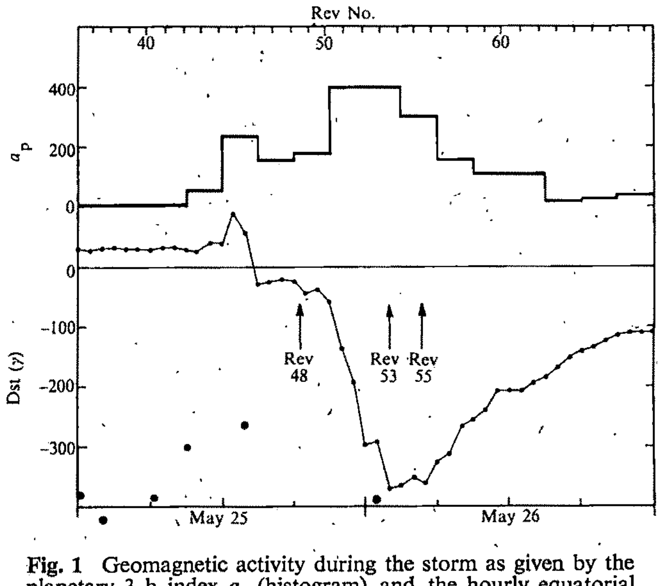

Fig. 1 Geomagnetic activity during the storm as given by the planetary 3 h index a_p (histogram) and the hourly equatorial Dst index. Rev, revolution.

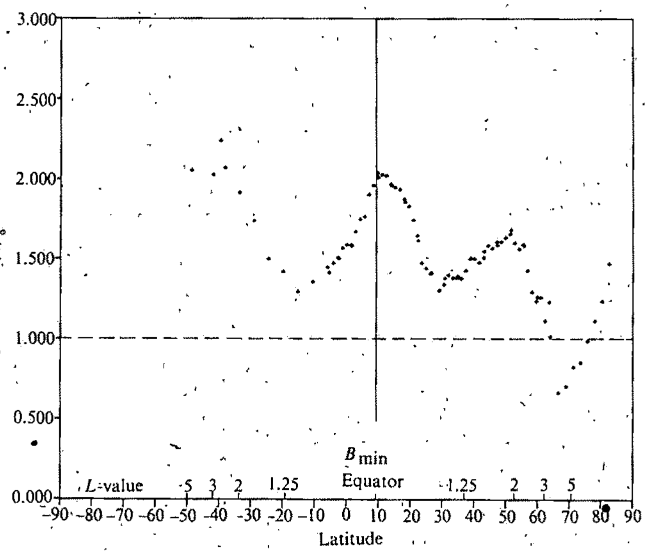

Fig. 2 The density ratio ρ/ρ_0, where ρ_0 is a standard quiet-time density, for the dayside pass on revolution 53 in the LOGACS experiment. The height of the satellite, which is near polar and passes southwards down the dayside at 1030 LT, is 165 km at 80° N falling to a minimum of 140 km at 40° N; then rising to 165 km at the equator and 305 km at 80° S. The magnetic equator and the feet of various L shells are also shown.

At the invitation of DeVries, we have made an independent analysis (R. R. A. and G. E. Cooke, unpublished) of the LOGACS data in which we concentrated on the dayside passes as these are more complete and contain the most clearly defined structures. The orbit is near-polar with the north-going passes on the nightside at about 2230 LT, and the south-going passes on the dayside at about 1030 LT. Perigee, at a height of 140 km, occurred on the dayside near 45° N, and the apogee height was between 300 and 400 km. For the dayside passes the response in both hemispheres can be compared, whereas on the nightside the vehicle is above 300 km, where the density values are much sparser and less reliable, south of the equator. The most clearly developed dayside response appears on revolution 53 just as the Dst index reaches its negative peak. The response is shown in Fig. 2 in the form of the ratio of the density on revolution 53 to a standard quiet-time density ρ_0, which has been derived (R. R. A. and G. E. Cooke, unpublished) from all the quiet-time passes up to revolution 41. Unfortunately, there is a gap in the latitude coverage from 50° S to 80° S in Fig. 2, but revolution 55 is essentially complete and is shown in Fig. 3.

The two figures are very similar; excepting the gap in Fig. 2, they show a wave-like pattern with a central maximum at 10° N, further maxima at 50° N and 40° S, and yet further maxima approaching the polar caps. The pattern is more nearly symmetrical (in form if not in magnitude) in magnetic coordinates, with the central peak on the magnetic equator and the mid-latitude peaks near $L=2$ in the Northern Hemisphere but perhaps nearer $L=3$ in the Southern Hemisphere. This slight asymmetry could result from the greater height in the Southern Hemisphere; alternatively the geometry could be imposing a compromise between geographic and geomagnetic latitudes. On the other hand, the greater magnitude of ρ/ρ_0 in the Southern Hemisphere probably arises simply from the greater height.

Although the gross structure of the response has a wave-like pattern, it is not a propagating wave. The dayside pass on revolution 54 is incomplete, but what there is shows the same latitude dependence and densities intermediate between revolution 53 and revolution 55. There are certainly small-scale wave-like features, such as the double peak at 50° N in Fig. 3, but I hesitate to interpret them as evidence for atmospheric waves.

The appearance of pronounced troughs near ±60° magnetic latitude is in complete agreement with DeVries[5,6]. The northern trough appears in both figures and reveals a minimum density of only 70% of the quiet-time value (at a height of 150 km) on revolution 53, rising to 85% by revolution 55. Two possible reasons might be that the air has been accelerated and displaced by electrodynamic forces or that the air is colder, due to the displacement of part of its normal heat source to lower latitudes.

The response time of the dayside thermosphere must be fairly short because the density at the peaks is at, or nearly at, its maximum on revolution 53. At the mid and high-latitude peaks the density perhaps increases marginally by revolution 55. The equatorial peak, however, has nearly disappeared by revolution 55, possibly because ion drag can offer negligible resistance to an expansion in latitude. On the other hand, the density between the peaks continues to increase for some hours. Eventually the structure collapses in irregular fashion —so irregularly that it might be said to disintegrate. The rapidity of the response and its approximate symmetry in magnetic coördinates indicate that the structure shows simply where the energy is injected into the atmosphere, at least in the morning sector, in an intense storm, namely, near the magnetic equator, near the particle precipitation zones which are displaced equatorwards in the storm and over the polar caps.

Moreover, the peak values of ρ/ρ_0 at the greater heights in the Southern Hemisphere exceed the corresponding peaks in the Northern Hemisphere and seem to be attained just as rapidly. The implication seems to be that a significant part of the energy input must raise the temperature fairly uniformly throughout the height range and is therefore possibly due to particle precipitation rather than Joule heating.

The most interesting feature of the response is the pronounced peak on the magnetic equator on revolution 53. As this pass coincides with the maximum negative excursion (−370 γ) of the Dst index, the obvious conclusion is that the equatorial peak is related to the growth and decay of the storm-time ring current. This conclusion is reinforced (R. R. A., unpublished) by the appearance of a similar, if less marked, peak on revolution 48 soon after the first negative excursion of Dst (Fig. 1). As has been pointed out[9–11], an important loss process for ring current protons will be the charge-exchange collision with neutral hydrogen atoms. The collision results in a fast neutral hydrogen atom which is later stripped at low altitudes (if it goes downwards) to recover a proton, which is then trapped until a third atmospheric interaction removes it, and so on. Subsequently other loss mechanisms, pitch-angle

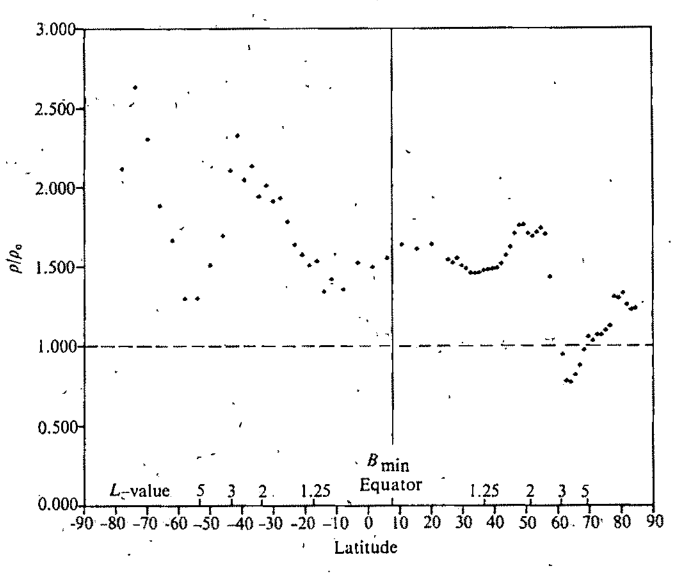

Fig. 3 The corresponding density ratio for the dayside pass on revolution 55, with the details as for Fig. 2.

diffusion due to Coulomb scattering or plasma instabilities, have been extensively discussed and the charge-exchange collision has been somewhat overlooked. Recently, however, new calculations[12] using data on hydrogen densities in the geocorona show that the charge-exchange collision ought to be the dominant loss mechanism below $L=4$. For a large storm, the ring current energy will typically[13-15] peak somewhat above $L=3$ with a sharp cutoff below $L=3$.

This interpretation of the equatorial peak is confirmed by recent particle measurements below $L=1.15$, which is the lower limit for orbits which can drift completely around the Earth. Moritz[16] finds an ever-present flux of protons near the magnetic equator which he interprets as resulting from charge-exchange losses from the quiet-time ring current. The flux is constant at quiet times (which is consistent with both production and loss processes being proportional to atmospheric density) but increases by up to a factor of three during geomagnetic activity; in fact the energy range (250 keV to 1.65 MeV) of the detector is well above the energy (5 to 50 keV) typical[13,14] of storm-time ring current protons. More extensive results[17] are now available from OV1–17 for the energy range 12.4 to 500 keV at about 400 km near the magnetic equator at local midnight. The flux of protons below 100 keV increases sharply at disturbed times, but above 200 keV the flux is relatively stable and in agreement with the AZUR results[16]. Mizera and Blake[17] find that the flux near 40 keV is particularly well correlated with the growth of the ring current.

If the interpretation is correct, the existence of a response sharply peaked about the equator allows one interesting deduction. At this height (~ 160 km) the lifetimes of any charged particles produced by the precipitating neutral hydrogen atoms must be much shorter than their bounce periods so that the response must reflect the energy input. For a dipole field line $r=L\cos^2\Lambda$, the centre of curvature at the equator lies at $2L/3$. Thus, the narrowness of the response cannot result from a geometrical focusing effect unless the source lies below about $L=2$, which seems unlikely, or unless the field is grossly distorted by the currents flowing. It therefore seems more probable that the part of the storm-time ring current responsible for the equatorial peak must be confined fairly closely to the equatorial plane. In support of this view, Frank[14] has noted that his observations "strongly suggest that these protons are injected into the outer radiation zone as an 'equatorial plasma jet' during the initial phase of a magnetic storm". Similarly, Sugiura[18] finds that the quiet-time ring current is closely confined to the equatorial plane.

The near disappearance of the equatorial peak by revolution 55 also calls for further comment. One possible reason would be that the storm-time ring current particles have acquired significant bounce amplitudes, so that the energy is being deposited over a wider latitude band. It seems more likely, however, that the closest part of the ring current has been removed by revolution 55, in line with the estimated[12] charge-exchange lifetime of 3 to 10 h at $L=3$. For a storm of magnitude $-150\ \gamma$ on April 17, 1965, Cahill[13] finds that a large part of the energy between $L=2.5$ and $L=3.5$ (estimated to be $\sim 10^{21}$ erg) is lost in less than 2 h.

The interpretation of the equatorial response as resulting from charge-exchange losses from the ring current is also in agreement with the results of May and Miller[19] on the response of the equatorial atmosphere (at about 310 km near noon local time) from the decay of the spin rate of Ariel 2 in March and April 1964. They noted that the density variations were more closely correlated with Dst than with a_p.

I thank Dr L. L. DeVries for encouragement and assistance.

African Swells, Magmatism and Plate Tectonics

WRIGHT[1,2] has revived Bailey's lateral compression model[3] for the generation of Africa's topographic swells[4-6] and the related igneous activity. Here I discuss some flaws in this approach, many of which persist in spite of its translation into plate-tectonic language.

Bailey regarded the gross "basin and swell" topography of Africa as the result of lateral compression of the continent, and he suggested that such regional updoming of the crust can bring about sufficient relief of lithostatic loading to cause melting in the deep crust (or below), to produce the characteristic East African igneous activity. Wright's variant[1] attempts a marriage between this scheme and modern global tectonics: here the entire lithosphere plate undergoes buckling, which is attributed to lateral stress attending opposed spreading at the mid-Atlantic and mid-Indian Ocean ridges[2].

To propose that pressure relief in the deepest parts of the crust is responsible for melting[3] clearly requires that the crust alone should suffer warping, the layer beneath being relatively free of lateral stress and deformation: pressure relief can only occur at the junction between deformed and undeformed layers. Such a suggestion implies a degree of decoupling between the crust and underlying lithosphere at odds with modern global tectonics, which emphasises the integrity of the entire lithosphere layer, and it is hard to think of a mechanism by which the crust alone could be subject to compression.

If, on the other hand, one considers that the lithosphere layer as a whole undergoes buckling[1], similar arguments restrict the possibility of load relief and melting to the base of the plate, at the lithosphere-asthenosphere interface. To suggest that significant pressure relief can be induced here by plate warping assumes an order of rigidity in the asthenosphere which is questionable. Fennoscandian and Hudsonian postglacial uplift rates are known to be of the order of 1 cm yr^{-1} (ref. 8). It seems, therefore, that asthenosphere flow can be rapid enough to compensate a lithosphere uplift taking place at this rate, which is nearly two orders of magnitude greater than the mean rate of doming uplift in East Africa (5,000 foot in $\sim 1.5\times 10^7$ yr according to ref. 4, page 1056). Since there is no evidence of deep partial melting associated with the postglacial relief of shield areas, one may argue that the probability of its occurring through compressional warping of similar terrains in Africa is insignificant. There is evidence that uplift in East Africa has been a discontinuous process, and it is arguable that intermittent spells of rapid uplift may have sustained melting, but the data above suggest that uplift rates 100 times greater than the observed average are required before melting is remotely possible. Such rates seem unlikely.

There is evidence too that lateral compression is not capable of producing Africa's swells. Ramberg and Stephansson[9] have analysed the effect of gravity on the maximum width of compressional warp structures, and have calculated an upper 'wavelength' limit of the order of 10 km. Comparison with the scale of the African features (200 to 500 km or more) points to the operation of some other mechanism. Moreover, the presence of tensional rift structures astride the swells belies the involvement of compression[10].

There are several petrological observations bearing on partial melting models. Bailey proposed that East Africa's abundant salic lavas derive from the partial fusion of deep-crustal rocks of alkali basalt affinity. Leaving aside the efficiency of pressure relief in producing melting[7], this idea fails to explain the coexistence at the surface of salic and basaltic volcanism, unless locally complete fusion is advocated. The origin of the basaltic reservoir and the reasons for its confinement to deep levels are unexplained.

Wright emphasises the mantle as the source of volcanism. There is, however, little petrological evidence that liquids as fractionated as trachyte or phonolite can form by fusion of ultramafic compositions. (If that were possible, why should the proportion of salic lavas be so much lower in oceanic islands than in the continents?) Rare high pressure xenoliths in trachytic rocks indicate high pressure fractionation[2] but not necessarily an origin by direct partial fusion of mantle rocks[11]. They are equally consistent with fractional crystallisation of bodies of mafic liquid confined near the base of the crust, a model which explains a variety of phenomena[12]. Moreover, any partial fusion scheme predicts that low-temperature melts such as trachyte should be sweated off from the mantle substantially earlier than basaltic liquids, a generalisation which is hard to reconcile with the simultaneous or alternating availability of both end members in many alkaline provinces.

I have assembled arguments showing that warping by lateral compression is at best an improbable cause of continental alkaline magmatism. The topography of Africa is now widely regarded as the product of heat flow anomalies in the upper mantle[6,7], from which the igneous activity where present may also be derived. I have argued recently[12] that the overabundance of salic magmas in the alkaline provinces of Africa and elsewhere, far from indicating highly specialised mechanisms for magma generation beneath the continents, merely reflects the influence of low-density continental crust on the transport of magmas of different types to the surface or present erosional levels. Thus the abundance anomaly which Bailey[3] and Wright[1] seek to explain may only be superficial, and there is little reason to adhere to a model of magma genesis which fits so few of the data now available.

I thank Drs A. D. Edgar and R. G. Park for comments and discussion.

Behaviour of the Earth's Palaeomagnetic Field from Small Scale Marine Magnetic Anomalies

CERTAIN areas of the ocean crust exhibit a high resolution recording of the magnetic field history. A recent survey[1] of the Gorda-Juan de Fuca Rise area in the North Pacific displays short wavelength (10 to 20 km), low amplitude (40 to 80 gamma) features superimposed upon the larger scale (30 to 200 km, 200 to 800 gamma) magnetic anomaly pattern of Heirtzler *et al.*[2]. Many of these small scale anomalies form lineations which are parallel to the major magnetic lineations of Heirtzler *et al.* Sequences of small scale anomalies form characteristic patterns within intervals previously thought to be of constant polarity. We have identified two of these patterns that we observed in the North Pacific on profiles from the South Pacific and South-east Indian Oceans. Because of their global distribution, we conclude that the small scale anomalies are due to time variations of the Earth's magnetic field. That is, these features record either short (less than 3×10^4 yr) polarity reversals or fluctuations in the intensity of the dipole moment, perhaps with periods greater than 3×10^4 yr.

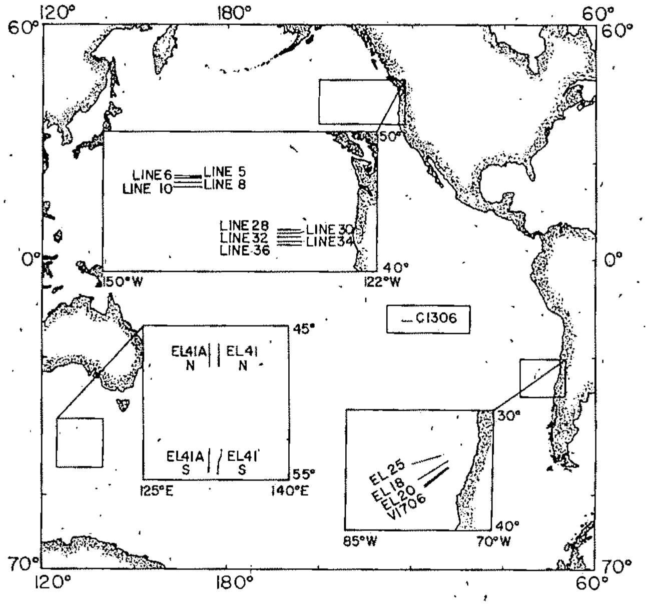

Fig. 1 Locations of profiles in Figs 2 and 3. Track prefixes: C, RV Conrad; V, RV Vema; EL, USNS Eltanin; LINE refers to Surveyor Seamap profiles.

The two sequences of small scale anomalies we studied in the North Pacific survey were between anomalies 12 and 13 (half-spreading rate 4.5 cm yr^{-1}) and between anomalies 5 and 5A (half-spreading rate 3.0 cm yr^{-1}): see Figs 2 and 3. On the east flank of the Chile Rise (half-spreading rate 4.5 cm yr^{-1}) the lineated small scale features between anomalies 12 and 13 show the same character as in the North Pacific survey area (Fig. 2). Similarly, the small scale features between anomalies 5 and 5A in the North Pacific can be recognised on magnetic profiles of both flanks of the South-east Indian Ridge (half-spreading rate 2.8 cm yr^{-1} on north flank; 2.3 cm yr^{-1} on south flank). These features can also be identified on the Conrad 1306 track (Fig. 3) which crosses anomaly 5 and 5A in the Central Pacific in an area of relatively fast spreading (half-spreading rate 6.0 cm yr^{-1}). This profile contains additional detail which may represent actual field behaviour recorded with higher resolution because of the fast spreading rate. It would be beneficial to conduct a survey of this area to determine whether this detail is repeated in other profiles.

To facilitate the correlations, we have phase shifted the various profiles according to the method of Schouten and McCamy[3]. The amount of phase shift is noted by the parameter Δθ in Figs 2 and 3.

The detailed behaviour of the Earth's magnetic field is not well known. The original reversal time scale of Heirtzler *et al.* identified no polarity events of duration less than 3×10^4 yr. Research on the magnetisation of rocks[4,5] and high sedimentation rate cores[6,7] however, suggests the existence of at least six short (less than 3×10^4 yr) polarity events during the past 2.4 m.y. Others[2,8,9] have correlated some of these events with small scale anomalies on marine magnetic profiles. Blakely and Cox[10] identified six additional short (less than 6×10^4 yr) polarity events in the early Cainozoic from magnetic profiles. Blakely[11] is revising the Heirtzler time scale between anomalies 5 and 6. He has identified many of the same small scale features that we have between anomalies 5 and 5A.

McElhinny[12] points out the possibility that some of the events identified from the magnetisation of rocks and high sedimentation rate cores may be due to polar excursions of the dipole field rather than complete polarity reversals. In addition, near-bottom magnetic surveys suggest that there are variations in the magnetisation intensity of the ocean crust due either to fluctuations in palaeomagnetic field intensity or variations in petrology[13,14]. Others[15,16] have noted the existence of dipole field intensity fluctuations with a periodicity of 10^4 yr.

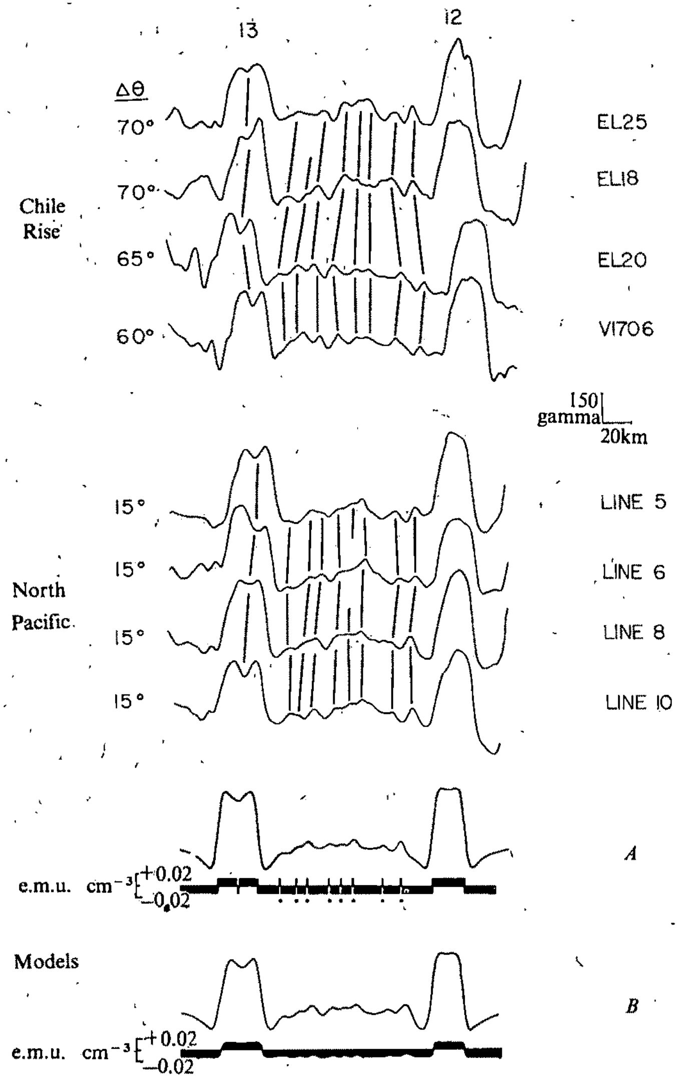

Fig. 2 Correlations of small scale features between anomalies 12 and 13. Models explained in text. Darkened figures represent magnetisation distributions. Dots in model *A* indicate locations of possible new events. Model *A* parameters: depth, 4.5 km; layer thickness, 0.5 km; smoothing (σ), 0.5 km; Δθ, phase shift parameter[3].

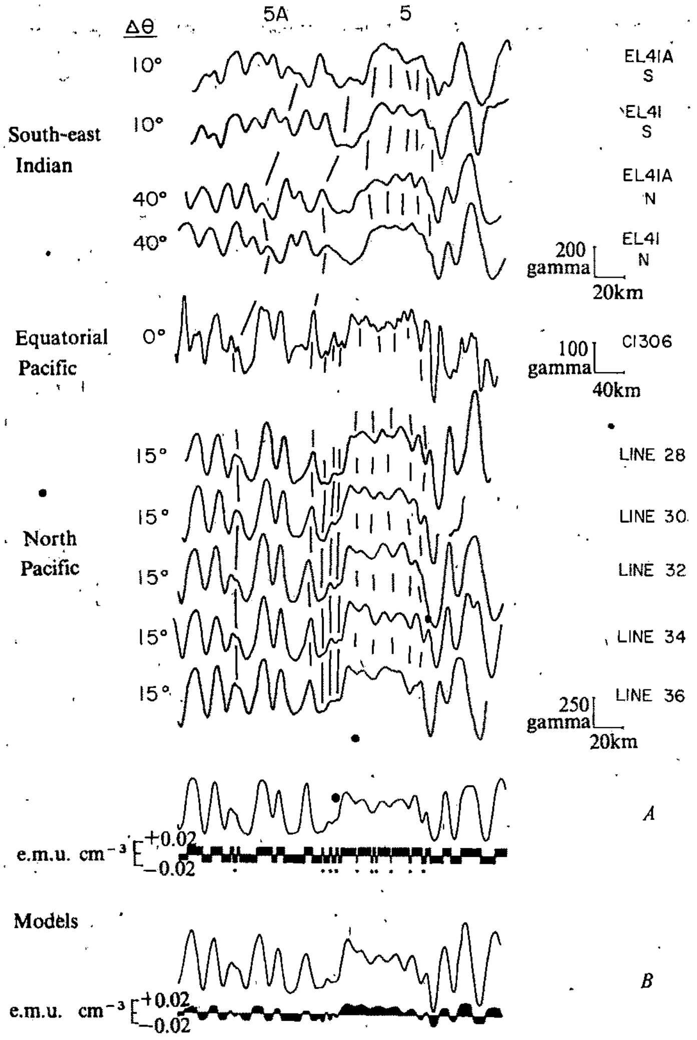

Fig. 3 Correlations of small scale features between anomalies 5 and 5A. Model parameters: depth, 3.5 km; layer thickness, 0.5 km; smoothing (σ), 0.5 km; Δθ, phase shift parameter[3].

Surface marine magnetic profiles lack sufficient detail to discriminate between a crustal magnetisation distribution due to short periods of reversed polarity and one due to intensity fluctuations in the palaeomagnetic field. Models *A* and *B* (Figs 2 and 3) demonstrate that both hypotheses can account for the observed small scale anomalies. Model *A* represents the 'reversal model' in which the field maintains constant intensity during periods of constant polarity. The duration of the polarity transition is assumed to be 5×10^3 yr (ref. 17). Model *B* represents the 'intensity fluctuation model' in which the intensity varies irregularly during periods of constant polarity. The models do not duplicate any one profile exactly. Instead they approximate the general character of all the profiles. The model magnetisation distributions have been smoothed with a Gaussian function to simulate the effect of such processes as dike injection and extrusion of lavas. The amount of smoothing is measured by the standard deviation, σ, of the Gaussian function[3,10]. Based on the results of near-bottom surveys[18,19] we assumed a standard deviation, σ, of 0.5 km.

Model *A* shows the possible location of short polarity reversals required to duplicate the observed anomaly pattern. These new events are almost all less than 3×10^4 yr in duration. We have inserted eight new events between anomalies 12 and 13 and 10 new events between anomalies 5 and 5A.

The existence of additional short period events in the time scale has been predicted by Cox[15] on the basis of a stochastic model. Assuming these features are due only to polarity reversals, the insertion of these new events changes the observed distribution of polarity interval lengths. Since these small scale features are seen throughout the time covered by the North Pacific survey area (40 m.y. BP to present), this suggests that the mean rate of polarity reversals may be considerably greater than previously estimated[2,15], perhaps by a factor of two. During intervals previously thought to be of constant polarity, the field may have behaved like a monostable oscillator, favouring one polarity more than the other. In particular, this behaviour may characterise the early Cainozoic where the Heirtzler *et al.* time scale identifies many long periods of constant polarity. Such monostable behaviour may be incompatible with a simple stochastic model like the Poisson process.

Model *B* demonstrates an alternative hypothesis that these small scale features may be due to intensity fluctuations within periods of constant polarity. The features were modelled by fluctuation with periods of 3×10^4 yr to 2×10^5 yr and amplitudes of 15% or more of the mean field intensity. The magnetisation shown in model *B* is not a unique representation of the actual field behaviour. The small scale features could be modelled by shorter period fluctuations of greater amplitude or the observed features may be artefacts of an even more complicated behaviour.

We considered the possibility that the intensity of fluctuations in model *B* might be explained by variations in the dipole moment of the field, variations in the intensity of the non-dipole field or variations in the pole position of the dipole field. The high coherence of the small scale anomalies recorded in different hemispheres over millions of years eliminates the possibility that they are due to variations in the non-dipole field. Variations in the pole position of the dipole field would have produced a phase difference of 180° between the variations observed in the Northern Hemisphere and Southern Hemisphere. This relative phase difference is not apparent in our profiles. Therefore, we conclude that the intensity fluctuations of model *B* would be due to variations in the dipole moment.

Near-bottom magnetometer profiles in areas where small scale lineated anomalies are observed at the surface may help to resolve the nature of the field behaviour responsible for the anomalies.

We thank W. Pitman, III, for his guidance and E. Herron, R. Larson, W. Lowrie, K. McCamy and P. Richards for their critical review of the manuscript.

North Sea Geothermal Gradients

REGIONAL studies of geothermal gradient patterns obtained from bottom hole temperature measurements in deep oil exploration boreholes have been the subject of several recent papers[1–3]. Harper[1] has produced approximate gradients in a study of the North Sea by the direct use of bottom hole temperatures routinely taken during the logging of exploration wells. These temperatures, which are taken with a maximum mercury-in-glass thermometer at a point typically 30 foot from the bottom of the hole, are, in general, less than the true formation temperature as a result of the cooling effect of the circulating drilling fluid.

The effect of such a thermal disturbance in a borehole may be approximated by a constant line heat source in a uniform infinite medium with a solution as a function of time, as derived by Lachenbruch and Brewer[4]. That solution, for a fixed depth in a borehole, is

$$T(t_2) = K\log(1+t_1/t_2) + T(\infty) \qquad (1)$$

where t_1 is the time of cooling the formation by the circulating fluid, t_2 is the interval from cessation of cooling to temperature measurement, $T(t_2)$ is the observed temperature at time t_2, $T(\infty)$ is the true formation temperature and K is a constant. Thus where multiple values of $T(t_2)$, t_1, and t_2 are known, equation (1) may be applied as a semi-log plot of $T(t_2)$ against $(1+t_1/t_2)$ to produce accurate formation temperatures at the

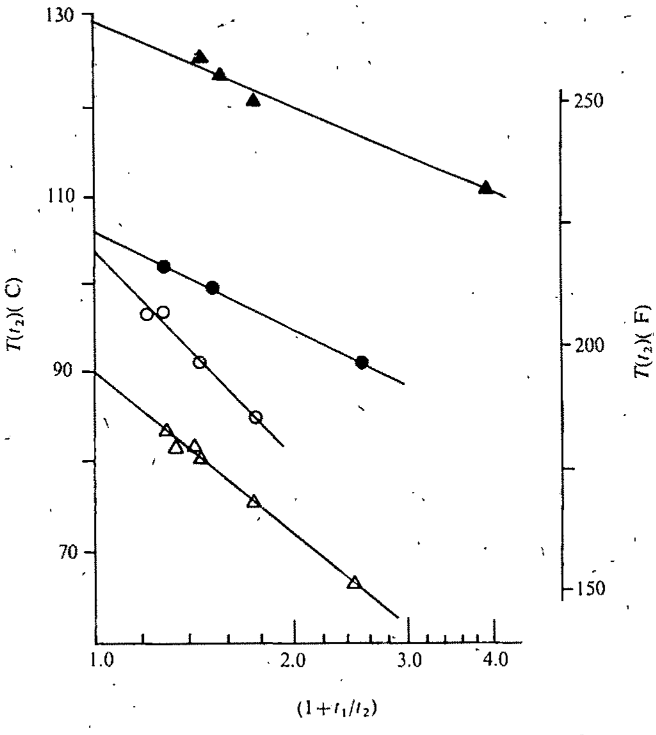

Fig. 1. Thermal recovery of four North Sea exploration boreholes. The temperature intercept is the true formation temperature. ▲, BP, UK; ●, Conoco, UK; ○, Amoco, UK; △, BP, UK.

linear axis intercept as was recently shown by Timko and Fertl[5].

Bottom hole temperatures from fifty-nine North Sea oil exploration wells, forty in the UK sector, fifteen in the Norwegian, and four in the Dutch, were studied and true formation temperatures calculated by the above method. Figure 1 is a semi-log plot for four typical wells. This method was also applied to a further forty-four results from the previous study by Harper[1]. These were additional data without t_1 values and it was, therefore, necessary to estimate this parameter statistically. The interval t_1, the total time of cooling, is the sum of the time taken to drill the final 30 foot of hole plus any additional time during which fluid circulates after drilling ceases. A log linear relation for drilling rate against depth was observed, while circulation time approximated a normal distribution. These results, based on data from forty-six North Sea wells, allow a satisfactory estimation of t_1 and provide a basis for the application of equation (1).

The determination of all geothermal gradients incorporated the subtraction of sea bottom temperatures from the true formation temperatures with all depths being calculated from sea bottom. Defant[6] showed that the bottom temperature of the central North Sea varies both with water depth and season of the year. Figure 2 shows the transformation of Defant's results to a mean annual temperature at sea bottom as a function of water depth. This result was combined with the true formation temperatures for the calculation of gradients. Geothermal gradients calculated from bottom hole temperatures uncorrected for the thermal disturbance of the drilling fluid would typically be lower than true gradients by 10–15%.

A geothermal gradient contour map, Fig. 3, is based on the total one hundred and three determinations with individual results being averaged over petroleum lease blocks which are 8 by 12 miles in the UK sector and somewhat larger in the others. As stated by Harper[1] and confirmed here, the regional trends seem to be governed by the major structural elements. The major sedimentary basins, English, SW Netherlands, German, Norwegian, East Shetlands, Moray Firth, and Midland Valley are all areas of high geothermal gradients with values locally reaching 44° C km^{-1}. Structural highs including Ringkobing-Fyn, Norwegian Platform, Mid North Sea, Mid Netherlands, and Grampian are characterised by low gradients which, south of Norway, approach 18° C km^{-1}. A geothermal high confirmed by four wells, located at approximately 55° N, 00° E, seems to confirm Armstrong's[7] opinion of the probable presence of Carboniferous coal-bearing rocks at a distance of one hundred miles from the Yorkshire coast trending ESE to fifty miles from the Norfolk coast. A thin stratum of coal above the bottom hole temperature measurement point with thickness 2–3% of that of the total formation would lower the overall thermal conductivity by approximately 25% due to its very low thermal conductivity[8], and could thus be a viable explanation of this anomaly. In addition there is a strong correlation, north of 56°, with the recently published Palaeocene isopach and base of Tertiary structure maps[9]. The coincidence of high geothermal gradients with the Tertiary depocentres reflects the lower thermal conductivity of this predominantly marine shale sequence.

North Sea in the positions indicated on Fig. 3 as well as the geothermal gradient, conductivity, and heat flow profiles. Estimates of thermal conductivity (Table 1) were made from published descriptions of the major lithological units of the North Sea together with the measured thermal conductivities of similar materials. Mean estimated heat flows of 75 mW m^{-2} from the southern profile (A-A′) and 71 mW m^{-2} from the northern profile (B-B′) were obtained, thus indicating no significant difference despite the higher gradients observed to the north. The values of heat flow, while slightly higher than the world mean[13], are intermediate in terms of other European basin values[1] and in good agreement with the world-wide mean for marginal seas[14]. A possibly significant aspect of Fig. 4 is that both heat flow profiles show an apparent decrease towards the European continent. This is consistent with world-wide heat flow means of 61.9 mW m^{-2} for post-Precambrian orogenic areas such as Great Britain and 38.5 mW m^{-2} for Precambrian shields such as Norway[14]. Seven recent combined heat-flow production measurements in Precambrian and Permian igneous rocks in southern Norway support such a value[15]. But, in general, the paucity of heat flow data in this area limits any attempt to confirm this trend.

Recent oil discoveries in the North Sea such as the Forties (57° 40′ N, 1° 0′ E) and Ekofisk (56° 30′ N, 3° 10′ E) fields seem to support the theories of Klemme[16] that high geothermal gradients enhance petroleum mobility, that is, migration to structural traps, to a greater degree than they adversely affect reservoir quality.

We thank the following oil companies for permission to use temperature data from their North Sea wells: Amoco, BP, Conoco and Phillips. We also thank Drs M. L. Harper and H. Y. Tammemagi for advice.

Quantitative Tar and Plastic Waste Distributions in the Pacific Ocean

WE report in this letter the first quantitative data on tar and plastic waste distributions in the surface waters of the Pacific Ocean. During the Canadian Transpac-72 cruise, thirty-seven surface tows were made with a neuston net to collect particulate pollutants quantitatively. (The net, a Kahl Scientific model with a mouth 80 cm by 30.5 cm and a 150 μm mesh net, was towed at 4 to 5 knots for 10 to 15 min at a time, covering an average area of 1,800 m^2. It was rigged so that it would tow off to the side of the ship through water undisturbed by the ship's wake.) The research ship, CSS Parizeau (track shown in Fig. 1), left Tokyo on October 10, 1972, proceeded easy along latitude 35° N to near the California coast, then turned north along 125° W to reach Victoria, British Columbia, on November 2, 1972.

The tar distribution is shown in Fig. 2. Tar was present in thirty of thirty-three tows along 35° N as black or brownish-black lumps up to 3 cm in diameter. Its concentration was consistently higher in the Western Pacific from Tokyo to waters north of the Hawaiian Islands with a maximum of 14 mg m^{-2} wet weight and an average of 3.8 mg m^{-2}—the same order of magnitude as the weight of the organisms caught in the neuston net. The concentration of tar in the Eastern Pacific was an order of magnitude lower on average. No tar was found along 125° W. These tar aggregates were inhabited by diverse biological communities: diatoms and bryozoans, usually on the smaller pieces, and blue-green algae and goose barnacles on some of the larger ones. Crabs, mostly still in the megalops stage, and, as in the Atlantic[1–3], the isopod *Idotea metallica* seemed to be living on the lumps. Thus, the tar is apparently not directly toxic to many species, although incorporation of small lumps into the food chain by way of surface-feeding fish and copepods has been suggested as a hazard[1,4].

As shown in Fig. 2, plastic is widespread, although in minute quantities. It was present in twenty-one of thirty-three tows along 35° N as small (0.1 to 0.5 cm), round, colourless pellets weighing 20 to 50 mg each. In contrast to tar, the maximum concentration of plastic was found in the Eastern Pacific (3.5 mg m^{-2}). The average concentration was 0.3 mg m^{-2}. The maximum number of pieces observed was sixty-two, corresponding to 34,000 pieces km^{-2}. None was found along 125° W. Smaller plastic pieces did not appear to support

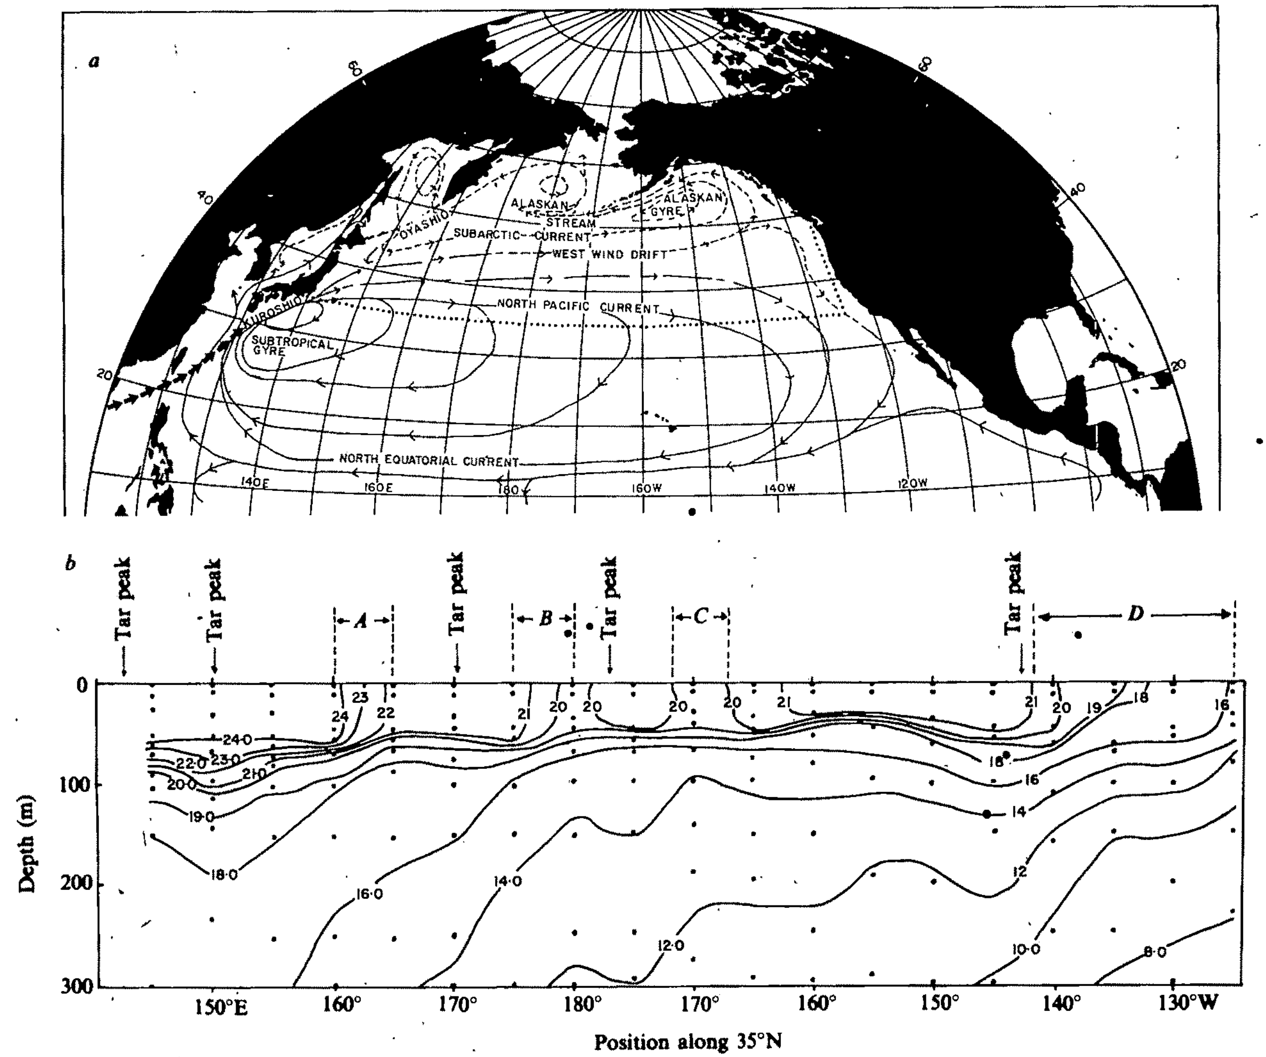

Fig. 1 *a*, Track of the CSS Parizeau on Transpac-72 cruise (···), the surface transport in the North Pacific Ocean[9] (cold currents, - - - ; warm currents, ——), and the Persian Gulf–Japan tanker route (heavy arrows). *b*, Temperature distribution (° C) in the surface waters along 35° N in the Pacific Ocean. The zones of influx of cold subarctic water (*A*, *B*, *C*, *D*) and the locations of the peak concentrations of tar are indicated.

a fouling community, although larger ones had growths similar to that on tar lumps of the same size.

Some paper, elastic bands and wood were present in the first few tows off Japan (up to 500 miles from Tokyo). None was found, however, in the remaining 6,000 mile journey.

The persistent tar distribution may result from several factors: likely sources from marine oil transport, augmented by accidental spills, prevailing wind transport and surface circulation.

First, an order of magnitude difference in 'possible-source' volumes of oil shipments to Japan and the west coast of the United States correlates well with a similar order of magnitude difference in tar for Western and Eastern Pacific waters, assuming that persistent tar originates mainly from tanker washings. In the North-western Pacific, 6,000 t.b.d. (thousand barrels per day) of crude oil were transported by tankers in 1971, 90% going to Japan along the Persian Gulf–Japan tanker route (Fig. 1). In the North-eastern Pacific, only 600 t.b.d. of seaborne crude oil were handled. The locations of the tanker routes do not, however, agree with the detailed distribution pattern of pelagic tar. (Information on oil tanker routes is from ref. 5.)

Second, prevailing winds are most effective in transporting surface pollutants. In general, a high concentration of tar in the Western Pacific between 150° E and 175° W and in the Eastern Pacific at 143° W is consistent with the mean annual wind stress over the North Pacific[6]. The wind stress tends to move surface pollutants eastwards in the Western Pacific to about 170° W where both a change to a southward direction and a weakening in wind stress takes place. The 143° W peaks of tar and plastic are in a region of zero annual wind stress, where accumulation of both tar and plastic is expected. This does not explain the absence of plastic in the Western Pacific, which possibly reflects the liberal input from the Hawaiian Islands relative to Japan.

Third, surface circulation also affects the long term distribution of surface pollutants. The cruise track of Transpac-72 at 35° N crosses an area influenced by both warm subtropical water and colder subarctic water. The fast moving warm Kuroshio Extension current flows east from 36° N, 140° E, in a remarkable meandering path up to about 160° E, where it transforms into the weak, broad North Pacific Current[7]. The waters further east undergo many seasonal and spatial variations due to mixing and incursion of cold subarctic water across the normal boundaries of the warm subtropical gyre water[8]. East of 140° W, the water is mainly of subarctic origin. The probable paths of intrusion of subarctic water can be inferred from a summary of North Pacific transport[9] and from the temperature distribution, both shown in Fig. 1: (*A*) 160° E to 165° E at about 22° C; (*B*) 175° E to 180° W with temperature slightly below 20° C; (*C*) 173° W to 167° W at about 19.5° C; (*D*) east of 142° W with very rapid drop in temperature from 21° C to 16° C at 125° W. (Figure 1 was modified to include recent data on the North Pacific circulation supplied

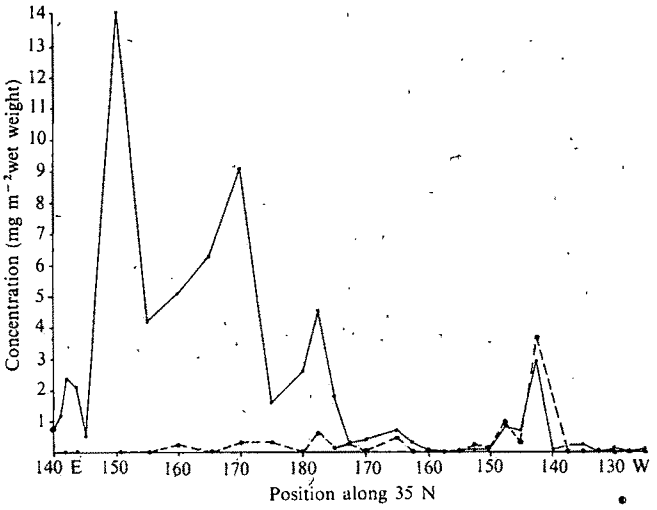

Fig. 2 Distribution of tar (——) and plastics (- - -) along 35° N in the Pacific Ocean. Tows covered an area of 1,800±300 m^2.

by R. E. Thomson.) The tar peaks at 150° E, 170° E, 178° W and 143° W seem to be in the slack, warmer subtropical water separated by the above zones of colder subarctic water, which have a low tar content. It is worthwhile to note that the time series at ocean weather station 'Papa' (145° W, 50° N) in subarctic water shows zero tar values (unpublished data of Ocean Chemistry Division, Marine Sciences Directorate, Pacific Region, Department of the Environment, Victoria, BC, Canada). Our observations are also in agreement with known features in the Atlantic[10] which show much higher concentrations of tar in the subtropical Sargasso Sea.

Due to the highly complex interaction of these three factors in the ocean, we cannot explain the waste distribution satisfactorily from one set of data. Our values in the Pacific, combined with those obtained in portions of the Atlantic and in the Mediterranean by other workers[1,2,10,11], do, however, indicate that the tar and plastic wastes are widespread on the surface of the oceans.

We thank William Heath for biological identifications, the captain and crew of the CSS Parizeau for help with the sampling and Drs R. W. Stewart and R. E. Thomson of Marine Sciences Directorate, Pacific Region, for criticism.

BIOLOGICAL SCIENCES

Replication of Yeast Chromosomal DNA

THE study of replication in higher eukaryotes has been hampered by the large size of the DNA molecules in their chromosomes. The yeast *Saccharomyces cerevisiae* is a eukaryote with very little DNA per haploid nucleus (9×10^9 daltons)[1]. This has facilitated measurement of intact yeast chromosomal DNA by sedimentation velocity[2] and electron microscopy[3]. The results indicate that yeast chromosomes are similar in size to those of viruses and bacteria, each chromosome containing a single DNA duplex ranging from 10^8 to 10^9 daltons. More than 95% of the chromosomal DNA molecules isolated from asynchronous cultures are simple linear structures, but the few branched structures are good candidates for replication intermediates[3]. We have used two experimental approaches which provide evidence that these exceptional molecules are, indeed, replication intermediates. Characterisation of these

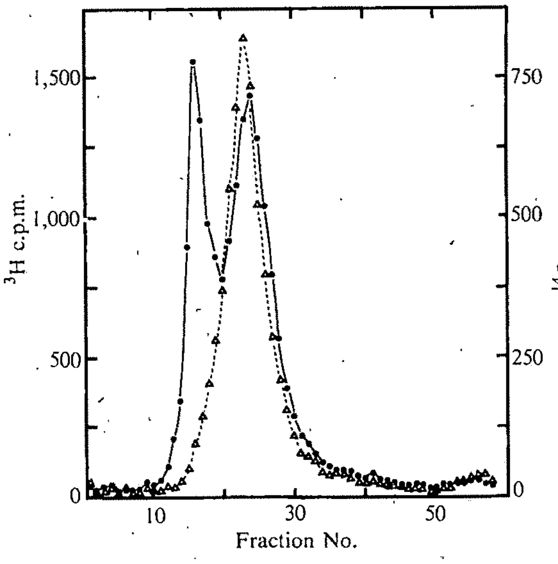

Fig. 1 Density profile of yeast DNA from a culture shifted from dense to light medium. A derivative of A364A D5 (ref. 13), A364A D5 U^+A^+, which does not require uracil and adenine was grown for many generations at 30° C in ^{15}N-D_2O medium containing 0.25 µCi ml^{-1} 2-^{14}C-uracil (New England Nuclear Corp., 0.5 µCi μg^{-1}). The medium contains (per litre) 1.45 g Difco yeast nitrogen base (without amino acids or $(NH_4)_2SO_4$), 10 g succinic acid, 6 g NaOH, 50 mg tyrosine, 20 g glucose, 100 mg $^{15}NH_4Cl$ (Isomet, Oakland, New Jersey) and 1 litre D_2O (Bio-Rad Laboratories, Richmond, California). The cells were filtered on Millipore HA filters and resuspended in Y-minimal medium (6.79 g Difco yeast nitrogen base (without amino acids), 10 g succinic acid, 6 g NaOH l^{-1}) supplemented with 20 g glucose and 50 mg tyrosine l^{-1} and containing 10 µCi ml^{-1} 6-^{3}H-uracil (New England Nuclear Corp., 250 µCi μg^{-1}). After incubation for 100 min, cells were collected by centrifugation and spheroplasted as described previously[2] at a concentration of 10^8 cells ml^{-1}. Spheroplasts were washed by centrifugation at 4° C with a solution containing 1 M sorbitol, 0.1 M sodium citrate and 0.01 M Na EDTA, *p*H 5.8, suspended in the same solution, and 0.3 ml (about 6×10^7 spheroplasts) was layered over 0.1 ml of 10 mg ml^{-1} pronase (previously treated at 70° C for 10 min) on top of 7 ml CsCl (Harshaw Chemical Co., Solon, Ohio) solution ($\eta=1.4040$) containing 0.01 M Tris-Cl (*p*H 8) and 0.01 M Na-EDTA (*p*H 8) in a centrifuge tube. The spheroplasts were lysed by the addition of 0.1 ml 10% sarkosyl. After 30 min at room temperature, gradients were overlayered with mineral oil and centrifuged in a Spinco 50 Ti rotor at 20° C and 33,000 r.p.m. for 60 h. Gradients were collected from the bottom of the tube through a 13 gauge needle, which had been boiled in 0.1 M EDTA, at a rate of less than 0.5 ml min^{-1}. DNA radioactivity was measured on 50 µl portions of gradient fractions as described previously[2]. ●, ^{14}C; △, ^{3}H.

molecules by electron microscopy indicates that yeast DNA replication is similar to higher eukaryotic DNA replication in two important respects. First, most and possibly all initiations are internal. Second, many chromosomes contain more than one replication unit.

Material enriched in replicating structures can be obtained by transferring cells from isotopically dense to isotopically light medium and banding the DNA in a density gradient. Partially replicated molecules have buoyant densities intermediate between unreplicated and completely replicated molecules. Figure 1 shows the buoyant density profile of yeast DNA prepared from a culture grown in dense medium and transferred to isotopically light medium 100 min before collection. The peak containing only ^{14}C radioactivity corresponds to fully dense DNA and the peak containing both ^{3}H and ^{14}C radioactivity contains hybrid density DNA. When DNA from the region between the peaks (fractions 19, 20 and 21) was examined in the electron microscope 31% (thirty out of ninety-seven) of the molecules seen contained either Y-shaped terminal forks or internal 'bubbles' (Fig. 2). These bubbles are similar to structures observed in λ (refs 4 and 5), T4 (ref. 6) or T7 (ref. 7) replicating DNA which result from pairs of diverging replication forks arising from single initiation sites. In molecules which were Y-shaped, two of the arms were equal in length. In the case of bubbles, the two branches between the forks were equal in length. These structures must be almost entirely composed of double stranded DNA because under the spreading conditions used single stranded DNA collapses on itself in 'bushes'[8]. However, small single-strand regions of the sort found in bacteriophage λ (ref. 10), T4 (ref. 6) and T7 (ref. 11) replication structures might not have been detected.

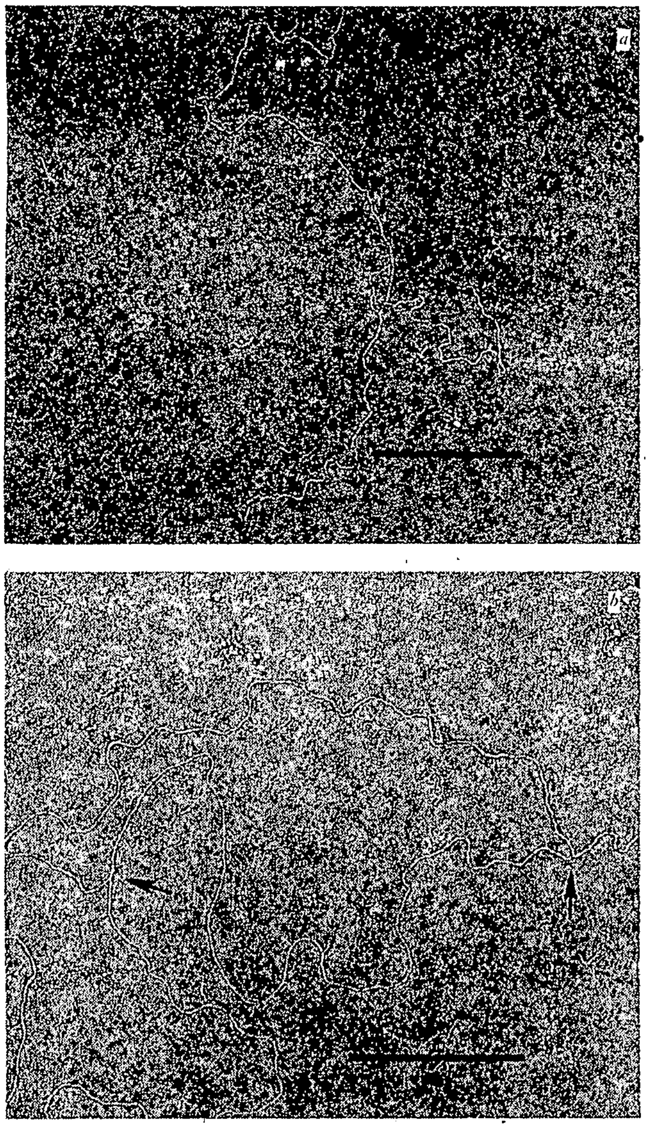

Fig. 2 Electron micrographs of portions of yeast DNA replication intermediates. DNA from CsCl gradients (Fig. 1) or sucrose gradients (Fig. 3) was spread using a modification of the aqueous procedure of Davis, Simon and Davidson[8] which has been described in detail[3]. Molecules were photographed using a Philips EM 300 electron microscope. Contour lengths in cm were determined using a Keuffel and Esser map measurer and were converted to microns by comparing the contour lengths of yeast DNA to the contour length of intact bacteriophage T4 DNA[3] spread under the same conditions. T4 DNA has a well characterized molecular weight (1.2×10^8) and contour length (52 µm)[9]. *a*, A Y-shaped fork with arms 2.2 µm long. *b*, A bubble with branches between the forks 5.5 µm long. The bars represent 1 µm. The arrows indicate forks.

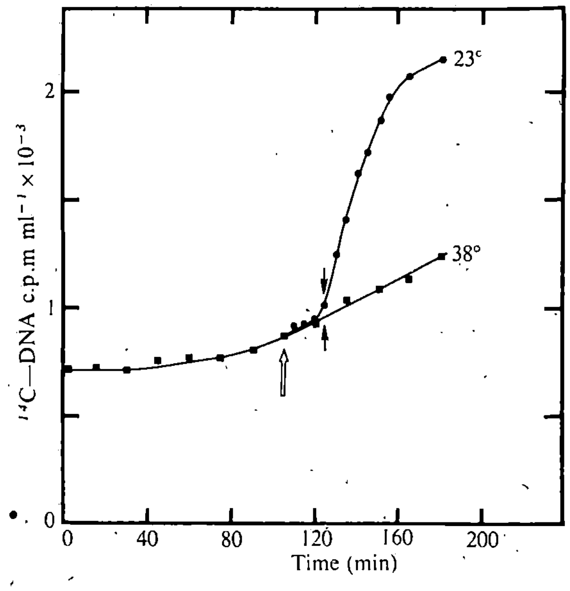

Fig. 3 Pattern of DNA synthesis in a synchronous culture. A culture of the temperature-sensitive cell division cycle mutant *cdc* 7 (strain 4008, obtained from L. H. Hartwell) was grown at 23° C in Y-minimal medium supplemented with 20 g glucose, 0.5 g yeast extract, 20 mg uracil, 20 mg adenine, 50 mg tyrosine, 50 mg histidine, and 50 mg lysine per litre and 1 µCi ml^{-1} 2-^{14}C-uracil (24 mCi mmol^{-1}, Schwarz/Mann) to a density of 2.5×10^6 cells ml^{-1}. To avoid holding cells at 38° C for a long time, the culture was synchronised by treatment with α-factor for one generation (3.5 h) as described previously[12]. To remove α factor, cells were filtered on Millipore HA filters, washed with 200 to 400 ml medium at 38° C and resuspended in the original volume of medium at 38° C ($t=0$). After 105 min at 38° C (arrow), the culture was divided and half was shifted to 23° C. Twenty minutes later samples were taken from each culture (small arrows) and DNA was prepared for electron microscopy by sedimenting it away from smaller cellular components on sucrose gradients as described previously[3]. Incorporation of ^{14}C-uracil into DNA was determined as described previously[13].

If these structures are associated with replication, samples from the fully dense and fully hybrid peaks should contain mostly simple linear molecules. In DNA from fraction 16 (Fig. 1), the peak of the fully dense region, seventy-nine out of eighty molecules examined were simple linear structures.

Replication intermediates should be found in cells in S phase, but not in cells at other stages in the cell cycle. To examine this we used a temperature-sensitive mutant defective in the initiation of DNA synthesis. In a culture of this mutant maintained at the non-permissive temperature (38° C), cells accumulate in the cell cycle just before DNA synthesis (unpublished results of L. M. H. and L. H. Hartwell). Figure 3 shows that when such a culture is shifted to the permissive temperature (23° C), it undergoes a synchronous round of DNA synthesis. The DNA synthesised in the culture maintained at 38° C is primarily mitochondrial DNA (unpublished results of C. S. N.). Twenty minutes after the temperature

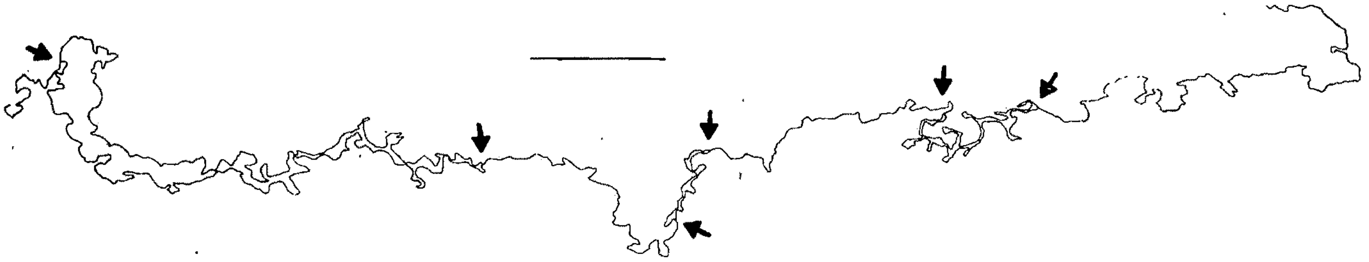

Fig. 4 Tracing of an electron micrograph of a replicating molecule. DNA was prepared and photographed as described in Fig. 2. The molecule shown is 117 μm long and the bubbles (right to left) are 13, 6, and 35 μm. Branch points are indicated by arrows. The bar represents 5 μm.

shift, samples were taken from the culture maintained at 38° C and the culture which had been shifted to 23° C (arrows, Fig. 3) and DNA was prepared for electron microscopy.

In the DNA from the sample collected at 38° C, 149 out of 150 molecules examined were simple linear structures. In the sample collected 20 min after the shift to 23° C, 66% (thirty-nine out of fifty-nine) of the DNA molecules observed contained bubbles or forks of the kind found in the density experiments. The correlation of such molecules, which are not present in the mutant at the restrictive temperature, with the burst of DNA synthesis, as measured by incorporation of radioactive label, is again consistent with the hypothesis that these molecules are replication intermediates. The total amount of DNA replicated in this sample can be estimated from the ratio of the sum of lengths of one arm of all bubbles and forks to the total length of all molecules measured. This ratio is 0.1 and is consistent with the incorporation data (Fig. 3), indicating that about 6% of a round of replication has occurred at the 20 min time point. The replicating molecules isolated from the cells in S phase varied in size from 47 to 250 μm. Thus, they probably represent intact chromosomal DNAs[3], and it is unlikely that extensive double-strand breakage occurs during the isolation of the molecules or during yeast replication.

From analysis of the data obtained in the synchronous culture experiment, a number of general conclusions can be made about yeast chromosomal DNA replication. The appearance of bubbles is most easily explained by internal initiation. Since most (thirty-four out of thirty-nine) of the replicating molecules contained bubbles, it is likely that most yeast DNA molecules initiate synthesis internally. The presence of Y-shaped molecules suggests either that there are some initiation sites at the ends of the chromosomes, or that internal initiations occur sufficiently close to the ends of some chromosomes that, after a small amount of DNA synthesis, a Y-shaped intermediate is formed. Bacteriophage T7 DNA has a Y-shaped intermediate throughout most of its replication although it initiates internally[7].

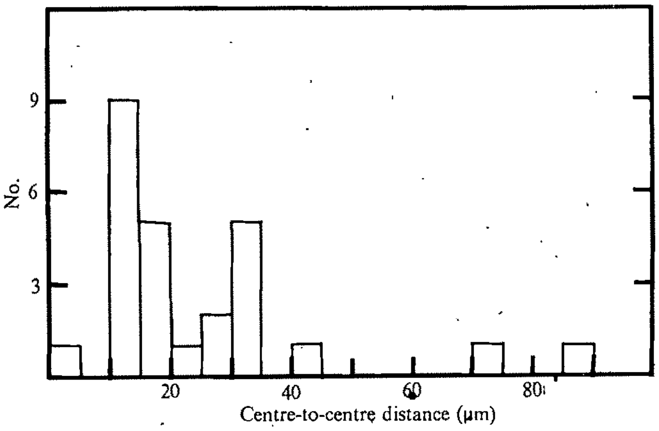

Fig. 5 Distribution of centre-to-centre distances between bubbles in molecules containing more than one bubble. Measurements of the centre-to-centre distances between bubbles in the replicating molecules from the experiment in Fig. 3 were made with a Keuffel and Esser map measurer on photographs at a magnification of 10,000.

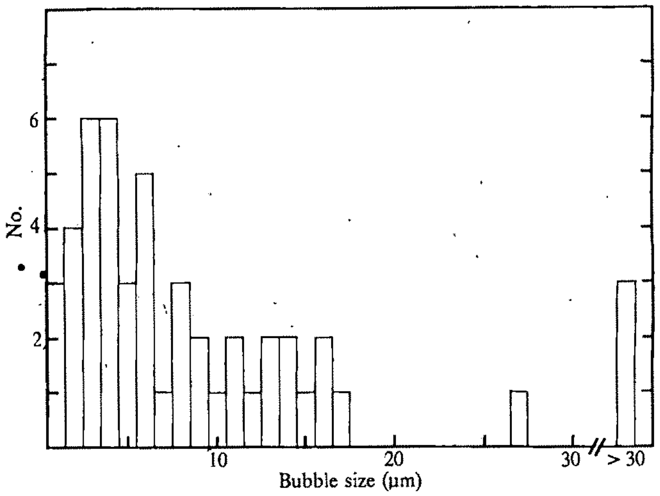

Fig. 6 Distribution of bubble size. Measurements of the size of bubbles in replicating molecules from the experiment in Fig. 3 were made on photographs at a magnification of 10,000 to 23,000.

At least some yeast chromosomes contain multiple initiation sites. In the S phase sample, 31% (twelve out of thirty-nine) of the replicating molecules contained more than one bubble. Figure 4 shows a tracing of a molecule with three bubbles. The size of replication units can be estimated from the spacing of bubbles along molecules. If a replication unit is defined as the amount of DNA replicated from a single initiation site, then a measure of the centre-to-centre distance between bubbles provides an estimate of this size[14]. The centre-to-centre distance between bubbles varied from 3 μm to 86 μm. Figure 5 shows that the distribution is not random; most of the distances fall into two clusters, one at 15 to 20 μm and the other at 30 to 35 μm. These values represent upper limits for replication unit sizes since some units may not have been activated in the observed molecules and some adjacent units may have already fused. Most bubbles are smaller than the smallest replication unit (Figs 5 and 6), so it is unlikely that many bubbles represent fused units. Thus it seems that replication unit size in yeast is more like that of higher eukaryotes[14,15] than that of prokaryotes[16,17].

The replication units on a chromosomal DNA molecule seem to initiate replication at different times. If all units initiated at the same time, then all bubbles on a molecule should be the same size (assuming that the rate of replication at all forks is constant); however, we find bubbles of varying sizes on individual molecules (for example, Fig. 4). The data also indicate that many yeast chromosomes in the synchronised cells initiate replication early in the S phase. This is shown by the fact that 65% of the molecules contained replication structures at a time when only about 10% of the DNA had replicated. Thus, at least 65% of yeast chromosomes initiate within the first 10% of S. This estimate could be in error for two reasons. Any asynchrony in the initiation of DNA synthesis among cells in the population would lead to an underestimate of the number of molecules which initiate synthesis at the beginning of S. In addition, mechanical shear during spreading of DNA could alter the apparent percentage of replicating molecules.

In summary, we find that yeast DNA replication intermediates include bubble-containing structures and Y-shaped structures. DNA molecules containing these structures are found in cultures in S phase, but not in cultures blocked before the initiation of DNA synthesis. In addition, there is at least a thirty-fold enrichment for molecules containing these structures in the region of a CsCl gradient where partially replicated molecules are expected to band. The same kinds of structures have been observed in DNA from asynchronous cultures[3]. Therefore, these structures cannot be attributed to abnormal growth conditions induced by density labelling or to the synchronisation procedure.

DNA replication in yeast is similar to replication in higher eukaryotes in several ways. Most, if not all, initiation sites are internal. Many chromosomes contain more than one replication unit, and the size of replication units is similar to that in higher eukaryotes. Because we can observe molecules which are almost certainly intact chromosomal DNAs, however, experiments which are very difficult to do in higher eukaryotes are possible. For example, replication maps of individual chromosomes can be made which include the location of initiation sites and the sequence of replication of different units.

Preferential DNA Repair in Human Cells

EXCISION repair plays a vital role in the recovery of human cells from ultraviolet irradiation[1], but it does not remove all lesions from DNA, even when they are as potent as cyclobutane pyrimidine dimers. In fact, only about 50% to 75% of the dimers produced by low fluences of ultraviolet light are excised and the remainder persist in the DNA for at least 24 to 48 h[2–4]. We have investigated why some but not all dimers are excised. Our conclusion is that dimers, and possibly other ultraviolet photoproducts, persist in tracts of DNA which are rendered refractory to excision repair by a 'mask' of protein.

Human fibroblasts (WI-38) were grown in culture, labelled with ^{3}H-thymidine, irradiated with ultraviolet light, incubated for various periods and then enzymatically assayed[5] for DNA damage by using a *Micrococcus luteus* extract containing repair endonucleases (see legend to Fig. 1). This assay mimics the first step of *in vivo* excision repair, namely the endonucleolytic nicking of DNA in the vicinity of pyrimidine dimers, so we expected that, if nucleoproteins did indeed interfere with excision repair *in vivo*, they would likewise interfere with the *in vitro* assay for DNA damage. To test this hypothesis the cellular DNA was assayed for damage after exposure to either low (less than 0.15 M) or high (2 M NaCl) concentrations of salt, that is, conditions which ensured that histones, and possibly other proteins, either remained bound to, or were stripped from[6], the chromosomal DNA. We did in fact find that exposing the chromosomal DNA to a high concentration of salt greatly increased the

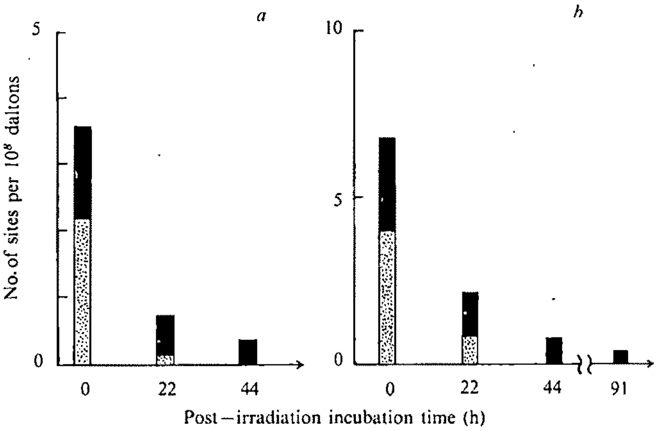

Fig. 1 Disappearance of ultraviolet-induced endonuclease sensitive sites from the DNA of human fibroblasts after 50 (*a*) or 100 (*b*) erg mm^{-2} of 254 nm ultraviolet light. The sites exposed under low salt conditions (dotted) and the additional sites exposed by high salt (black) were assayed essentially by the method described elsewhere[5]. Approximately 100,000 cells (WI-38 originally derived from embryonic lung tissue) were plated into 60-mm plastic dishes and incubated overnight in Eagle's medium with 10% dialysed foetal calf serum and 1 µCi of ^{3}H-thymidine added to label the DNA. After ultraviolet irradiation, cells were re-incubated for various times and then harvested by scraping into ice-cold saline-EDTA solution. For the endonuclease assay the cells were first rendered porous by osmotic shock, that is, they were concentrated to 5×10^6 cells ml^{-1} in 10% sucrose, then diluted six-fold in water and vortexed. The sample was then divided into two, one of which was made 2 M with respect to NaCl and kept at 0° C for 5 min. Both samples were then diluted a further ten-fold with water and then incubated with *M. luteus* extract for 12 min at 37° C. Fifty microlitres of each sample was then layered on an alkaline sucrose gradient so that the cellular DNA content could be sedimented through alkali to detect single-strand breaks produced by endonuclease action, that is, endonuclease-sensitive sites[5]. In control experiments using either unirradiated cells or no *M. luteus* extract, the weight average molecular weight of the DNA was always in the range of 0.9 to 1.1×10^8 daltons, so we normalised all our results to the number of endonuclease-sensitive sites per 10^8 daltons of DNA. These values are accurate to within ±0.1 site.

yield of detectable endonuclease-sensitive sites (Fig. 1). In cells which were assayed immediately after ultraviolet irradiation and had, therefore, no chance to repair DNA damage, over 60% more sites were revealed by the high salt assay. In other words, at least 40% of the chromosomal DNA is normally inaccessible to exogenous repair endonucleases used in the *in vitro* assay. This is a conservative estimate because some reassociation of protein and DNA probably occurs when the 2 M NaCl is diluted ten-fold to perform the assay. We do not believe, however, that much more than 50% of the DNA is inaccessible because in earlier experiments[5] employing low salt concentrations it was estimated that about half of the dimers induced in the DNA did give rise to detectable endonuclease sites.

The sites which are normally inaccessible to the exogenous repair endonucleases also seem to be relatively inaccessible to the DNA repair systems which act *in vivo*. Thus, while all of the ultraviolet-induced sites initially detectable under low salt assay conditions are removed from the DNA of cells during 44 h of post-irradiation incubation (Fig. 1 and ref. 5), many of the additional sites exposed by the high salt assay still persist in the DNA. For instance, 44 h after exposure to a fluence of 100 erg mm^{-2} of ultraviolet light, 28% of these additional sites still remain in the DNA and, even after 91 h, 13% still persist (Fig. 1).

The simplest explanation for our results is that some tracts of DNA are masked from the action of repair enzymes by sheaths of nucleoprotein. *In vitro* this protein can be removed from the DNA by high salt concentrations while *in vivo* it seems that repair systems can slowly gain access to the DNA, possibly because of changes that occur in DNA-protein complexes during DNA replication, or cell division, or both. We estimate that about 40% of the DNA is masked in this way and that the tracts covered with protein are no more than 10^8 daltons long because when using the low salt assay we did not observe any higher molecular weight DNA which was free of endonuclease-sensitive sites. Such conclusions are reasonable because it is known that about half of the DNA in the chromatin of mammalian cells is 'open' and linked together by many short tracts of DNA covered with protein[6].

Two general comments on our results are appropriate. First, it is possible that damage induced by agents other than ultraviolet light could also persist in these masked tracts of DNA and, as mammals age, their cells might accumulate such damage, especially in the absence of cell division. Second, differentiated cells might tolerate considerable damage in these masked, and possibly genetically unexpressed[7], portions of DNA. Thus the de- or re-differentiation of a cell might have a lethal, mutagenic or possibly carcinogenic[8] consequence if expression of this DNA occurred before repair could take place.

We thank J. S. Cook and R. B. Setlow for their comments. R. J. W. was supported by a fellowship from the Damon Runyon Memorial Fund for Cancer Research. This research was supported by the US Atomic Energy Commission under contract with the Union Carbide Corporation.

Note added in proof. Recent work[9,10] using a similar technique also indicates that there are both fast and slow components to the repair system which removes ultraviolet-induced endonuclease sensitive sites from the DNA of human cells.

Histone mRNA and Histone Synthesis during Embryogenesis

PROPORTIONAL contributions of individual histone fractions to total histone and their degree of microheterogeneity change during development. This has now been established for many plants and animals[1,2] including sea urchins[3-6]. The very lysine-rich histones, designated F1, can be fractionated as several proteins of similar amino acid composition[7,9] and as different phosphorylated derivatives[10,11]. These histones in particular show considerable species specificity in primary structure, molecular weight, and microheterogeneity[8,9,12,13]. It has been demonstrated in earlier studies[3-6] that aside from changes in proportion among histone classes synthesised during sea urchin development, synthesis of an F1 characteristic of the morula stage (F1-m) gives way to synthesis of a new and electrophoretically distinct F1 at the gastrula stage (F1-g). Significantly, the F1-m histone is neither degraded nor converted to F1-g during the interval from morula to gastrula[6].

We report here experiments designed to distinguish between two alternative modes of control over these developmentally programmed changes: differences in the template RNA from which histones are translated and

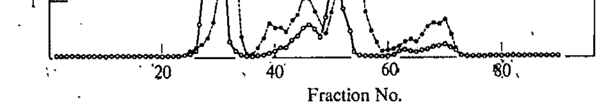

Fig. 1 Acetic acid-urea acrylamide gel electrophoresis of *L. pictus* embryo histones labelled *in vivo*. Two millilitres of morulae (approximately 2×10^6 embryos at about 100 cells) was incubated in 100 ml sterile seawater with 200 µCi ^{3}H-lysine (20.8 Ci mmol^{-1}) for 1 h. Two millilitres of gastrulae (0.5×10^3 to 1.0×10^3 cells) was incubated in a volume of 100 ml with 20 µCi ^{14}C-lysine (260 mCi mmol^{-1}) for 2 h. Histones were isolated[21] and dissolved in 2.5 M urea, 0.9 N acetic acid, 0.2% 2-mercaptoethanol. Electrophoresis was at 2 mA per gel for 5–6 h on 10% acrylamide, 2.5 M urea, *p*H 2.7 acetic acid gels, 14 cm long[18]. The histone-containing portion of the gel was sliced and hydrolysed for counting. ○—○, ^{3}H-lysine morula histones; ● - - - ●, ^{14}C-lysine gastrula histones.

differences in the way histones from an invariant soluble pool associate with DNA in the chromatin. The experiments are designed also to distinguish between primary structure differences and differential modification after synthesis as the chemical basis for the different electrophoretic mobilities of F1-m and F1-g.

Newly synthesised histones of *Lytechinus pictus* morulae and gastrulae were first examined by acetic acid-urea gel electrophoresis of the proteins labelled in a pulse exposure to ^{3}H-lysine[14]. The results are shown in Fig. 1. Morulae synthesise a lysine-rich histone (F1-m) that migrates more slowly in this electrophoretic system than does the F1 made by gastrulae (F1-g). Proportional differences of incorporation among the other four histone classes, particularly in the ratio F2b/F2a2, were observed as usual[6].

Morula and gastrula histones were then separated by electrophoresis on sodium dodecyl sulphate (SDS) gels, according to the method of Laemmle[15]. This analysis shows (Fig. 2) that morulae synthesise only F1-m, with molecular weight ≃20,000. First observed between hatching and gastrulation is the synthesis of F1-g (molecular weight ≃21,000). By the time gastrulation is in progress, incorporation of tracer amino acid into F1-m is greatly reduced and labelled F1-g accounts for most of the new F1. Electrophoretic mobilities of F1-m and F1-g are not altered detectably in either separation system after treatment with alkaline phosphatase (data not shown here). Seale and Aronson[4] report similar findings in experiments with another species, *Strongylocentrotus purpuratus*.

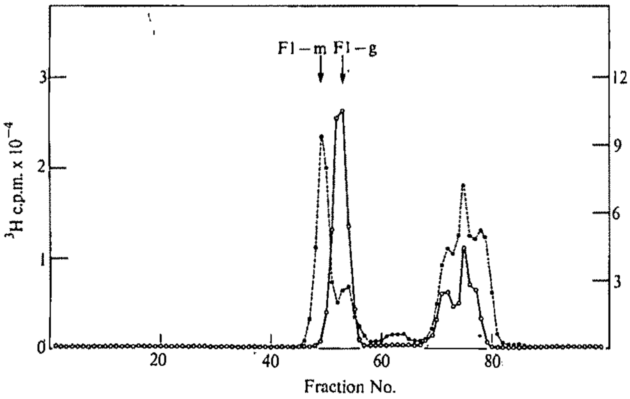

Fig. 2 SDS acrylamide gel electrophoresis of morula and gastrula histones. Histones, prepared as described under Fig. 1, were dialysed against 0.1% SDS, 0.2% 2-mercaptoethanol, and separated on 12.5% acrylamide-SDS gels[19]. ○—○, ^{3}H-lysine morula histones; ● - - - ●, ^{14}C-lysine gastrula histones.

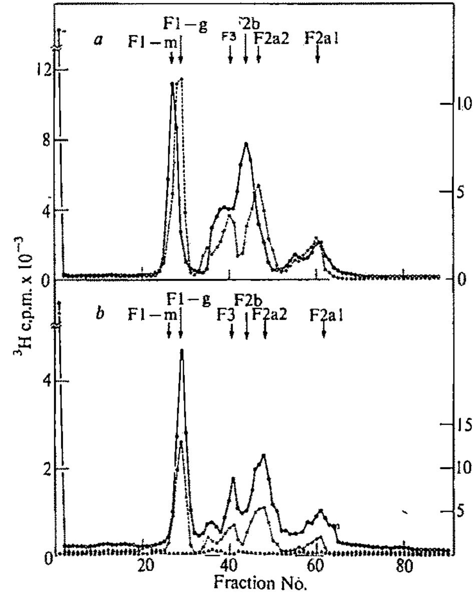

Fig. 3 Electrophoresis of products of cell-free protein synthesis on *p*H 2.7 acrylamide gels. 46 µl of the reaction mixture described in Table 1 was treated with DNase I (50 µg ml^{-1}) at 30° C for 20 min and then dialysed against 2.5 M urea, 0.9 N acetic acid, 0.2% 2-mercaptoethanol at 4° C. ^{14}C-lysine-labelled gastrula histones (*in vivo* marker) were added to the dialysed sample. The mixture was separated as described under Fig. 1. Only the histone-containing region is shown. *a*: ○—○, cell-free products directed by morula RNA; ● - - - ●, product of synthesis *in vivo* at gastrula stage. *b*: ○—○, cell-free products directed by gastrula RNA; ● - - - ●, gastrula marker histones; ▲ - - - ▲, cell-free products, no added RNA.

Total polyribosomal RNA was next prepared, purified, and translated in the ascites cell-free protein synthesis system employed by Gross *et al.*[16] for earlier studies on histone mRNA. Protein products of cell-free synthesis (Table 1), together with marker histones synthesised *in vivo* at the gastrula stage, were subjected to co-electrophoresis on acetic acid-urea gels. As is shown in Fig. 3*a*, RNA from morula polyribosomes directs the synthesis of F1-m. Total histones synthesised *in vitro* under direction of this RNA also give a high F2b/F2a2 incorporation ratio, which is characteristic of labelled histone that associates with chromatin *in vivo* at this stage of development. Gastrula polyribosomal RNA, by contrast, directs the cell-free synthesis of F1-g (Fig. 3*b*). The gastrula RNA-directed histones have the low F2b/F2a2 incorporation ratio characteristic of protein synthesis in the living embryo at this stage. In electrophoresis on SDS gels (Fig. 4), protein products made *in vitro* under the direction of morula RNA are again observed to contain only F1-m, while polyribosomal RNA from gastrulae yields products that separate on these gels as F1-g and a small amount of F1-m.

The postribosomal supernatant fraction of these embryos contains RNA with template activity in the cell-free system. Morula RNA of this kind directs the morula-specific pattern of lysine incorporation; little or no F1-g is labelled. Gastrula supernatant RNA contains sequences that encode and direct the synthesis of F1-g (data not shown here).

Polyribosomal (messenger) RNA from two different stages of development therefore contains sequences that direct histone synthesis *in vitro* according to patterns that match qualitatively, and to a considerable extent quantitatively, the corresponding patterns of synthesis *in vivo*. Mobility differences between the very lysine-rich histones encoded on and directed by the two kinds of template RNA are

Table 1 Cell-free Lysine Incorporation into Proteins Directed by Morula and Gastrula Polyribosomal RNA

Addition	^{3}H-lysine incorporated (c.p.m.)	Stimulation (X blank)
Blank (no RNA)	495	—
Morula RNA	6,126	12.4
Gastrula RNA	3,612	7.3

Polyribosomal RNA was prepared from 6 ml packed morulae and 8 ml gastrulae. Embryos were washed twice with $Ca^{2+}-Mg^{2+}$-free seawater, once with TNM (0.2 M NaCl, 5 mM Mg acetate, 10 mM Tris, *p*H 7.5), and homogenised in 2.5 volumes of TNM. The 12,000*g* supernatant was centrifuged through a 7–47% sucrose gradient for 3 h at 26,000 r.p.m. in a Spinco SW27 rotor. Polyribosomes were collected from appropriate fractions and their RNA extracted. This RNA was translated in the Krebs II ascites-derived cell-free system[16,22,23]. Input RNA was at 22.5 µg, prepared from morulae and gastrulae. The incubation system contained 10 µC ^{3}H-lysine at 20.8 Ci mmol^{-1}, plus 50 µM unlabelled amino acids (less lysine), in a volume of 50 µl. Incubation was for 60 min at 30° C. Two aliquots of 2 µl from each incubation were precipitated with hot 5% trichloroacetic acid and the precipitated radioactivity counted.

very likely to be due to differences in primary structure of the two proteins. The differences can in any case not be due to differential post-translational modification or derivatisation, since the information content of the two mRNA preparations is expressed through a constant enzymatic machinery, the components of the ascites cell-free incorporation system.

We conclude, therefore, that histones F1-m and F1-g of morulae and gastrulae, respectively, co-migrating as they do with corresponding products of cell-free synthesis directed by morula and gastrula RNA, also differ in their primary structures.

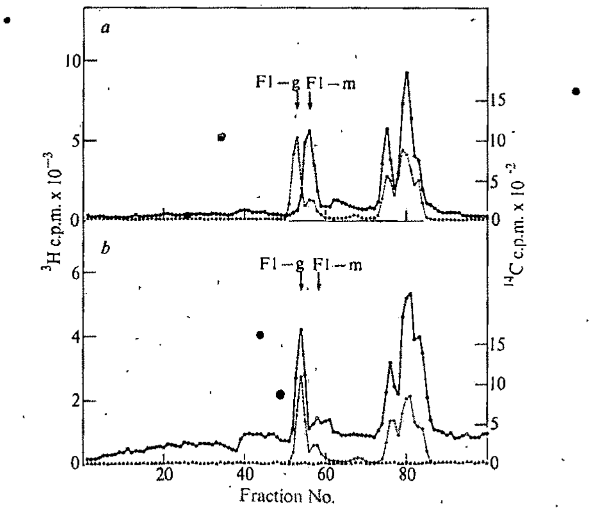

Fig. 4 Analysis of cell-free products on SDS-acrylamide gels. Morula or gastrula RNA was incubated with the cell-free protein synthetic system as described, and co-electrophoresis with ^{14}C-lysine gastrula marker histones was carried out as in the experiments of Fig. 2. *a*: ○—○, morula RNA-directed cell-free products; ●---●, gastrula marker histones. *b*: ○—○, gastrula RNA-directed cell-free products; ●---●, gastrula marker histones; ▲---▲, cell-free products, no added RNA.

Although other cases of histone tissue specificity are known[22,23], histone F1-g, which becomes detectable only after hatching in *Lytechinus* and other sea urchins[4,6], may be an example (so far rare) of a qualitatively new histone appearing in the course of early development. It is possible, of course, that traces of F1-g are present in pre-hatching stages and are not detected by methods such as were employed here, but this hardly affects the argument. Quantitative changes in the fractional synthesis of histones other than the F1 appear also to be regulated, at least in part, by the relative amounts of their corresponding messenger RNA in polyribosomes.

The situation in *Arbacia punctulata*, another species studied by the methods described above, is in essence the same as in *Lytechinus*, but with some minor modifications. Mobility relations between the two *Arbacia* F1 fractions differ from those of *Lytechinus* when the proteins are separated on acetic acid-urea gels. SDS gel electrophoresis reveals that the switch-over occurs earlier than in *Lytechinus*, and it seems to be completed by the late gastrula stage.

The data indicate, in summary, that the kinds and amounts of histones that associate with DNA in chromatin do in fact differ characteristically from one stage of development to the next and that the differences are in large part the result of differential messenger content of the translational machinery.

Geographical Distribution of Australia Antigen Determinants d, y and w

AUSTRALIA antigen (Au) has a group of antigenic determinants on its surface, which may occur in different combinations in the sera of people living in different geographical locations. Several of these determinants have been characterised and given alphabetical designations[1–5]. It has been reported that determinants d and y tend to be mutually exclusive[6] although rarely they occur together (S. M. and S. B., unpublished). Determinants w and r also tend to occur in different samples rather than together and these two determinants have a strongly marked geographical distribution. Determinant w is common in the USA, South America, Europe and Africa, while r is common in Asia and the Pacific area[5,7]. We have tested 893 samples of Australia antigen from locations around the world for determinants d, y and w. Here we present these findings and speculate on factors which may contribute to the geographical distribution of Australia antigen subtypes.

The Australia antigen samples included in this study were all from apparently healthy asymptomatic carriers. They are part of the blood collection of the Division of Clinical Research at the Institute for Cancer Research and had previously been found to contain Australia antigen by immunodiffusion testing. Australia antigen determinants were identified using the standard seven hole immunodiffusion pattern cut in 1.1% agarose in pH 8.2 veronal buffer[8]. Specific typing sera were put in the centre well, control Australia antigen was put in the top and bottom wells, and test samples in the remaining four wells. Human anti-aw was reacted against an aw control antigen adjacent to the test samples. The formation of a line of identity between the control antigen and the test antigen was interpreted as indicating that the test antigen was w^+. When a spur was formed by the control antigen over the test antigen it was considered w^-. The same principle was used in testing for determinant d with guinea pig anti-ad antiserum (NIH V 801–502–058). A few sera which were known to be Australia antigen positive did not react with this serum at all. These will be considered in detail elsewhere, but here they were considered d^-. These and all other d^- sera were retested with a second anti-ad serum for confirmation of their d^- status. Absorbed chimpanzee anti-y and y control antigen were used to test for determinant y. Sera which were negative for both d and y were tested with an additional anti-ay serum.

The antigens have been grouped according to geographical origin of the sera and have been assigned to subtype categories suggested by Le Bouvier[6] according to the presence of determinants d and y (Table 1). Subtype A consists of those antigens which lack both the d and y determinants. This group is designated A because by definition it must have determinant a which is defined as the universal or group determinant. The subtype categories have been further divided into w^+ and w^-. In all but four cases, determinants d and y were found to be mutually exclusive. These are not shown in Table 1. Two of these four exceptions were found on Bougainville and the other two were from people living in the United States who had travelled in Asia.

Australia antigen with determinant d is common in asymptomatic carriers in the United States, North Europe, Asia and Oceania, although subtype y does occur in these areas. All antigen samples from Japan carry the d determinant while none carry y. Antigen with the y determinant occurs almost to the exclusion of d in Africa and in Australian aborigines. Determinant y occurs frequently in India and in the Mediterranean area in Italy and Yugoslavia.

Virtually all antigens from Europe, the United States, Africa, India and Australia carry the w determinant. Antigen without w predominates in the New Hebrides, Micronesia, New Caledonia, Bougainville, Japan, Malaita and Thailand (Table 2). Both w^+ and w^- occur in the population in China, the Philippines, French Polynesia, and New Guinea.

From these data and the data in Table 2, it seems that there are marked geographical separations of subtype. The basic northern European subtype is $adw^+ y^-$ and the African subtype is $ayw^+ d^-$. In the Mediterranean area these subtypes both occur concurrently. The Asiatic type seems to be mostly $adw^+ y^-$ with some $ad^+ wy^-$. Large areas of

Oceania are ad^{+} wy^{-}. Japan is at a geographical interface with both adw^{+} y^{-} and ad^{+} wy^{-}. India and Australian aborigines are mostly ayw^{+} d^{-} and Melanesia is in the interface between Australia (ayw^{+} d^{-}) and the rest of Oceania (ad^{+} wy^{-}).

Figure 1 shows the distribution of dominant subtypes from different parts of the world tested in this study.

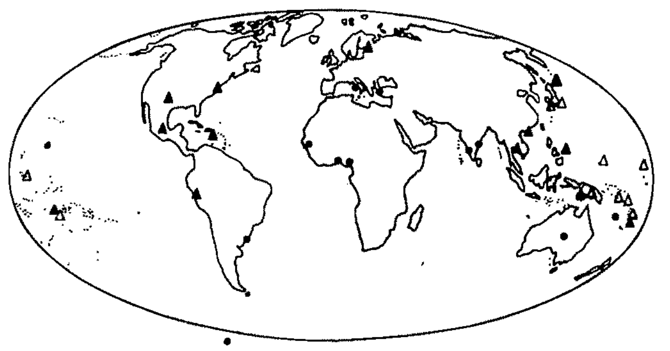

Fig. 1 Distribution of Australia antigen subtypes. Each symbol represents the dominant subtype in that location. Triangles represent subtype d. Circles represent subtype y. Solid figures represent w^{+}; open figures w^{-}.

One hypothesis generated by this study is that the Australia antigen subtypes among asymptomatic carriers could be used as population markers and serve as an indication of human migrations. This would be more likely if women were included in the migration since when women carry the antigen they can transmit it to some of their children who may then become chronic asymptomatic carriers[9-14]. When infants acquire Au from their mothers the subtype seems to be the same in both the mother and child[14,15]. Daughters can then transmit the same subtype to their children and so on through many generations. This could mantain the subtype brought by the migrant population in a new environment. These introduced subtypes might not predominate since there are other mechanisms which produce carriers, but they should persist to some degree.

The subtype ayw^{+} d^{-} is most common in Africa. In all areas tested where African slaves were introduced the ayw^{+} d^{-} subtype occurs but in lower frequency than in Africa. These areas include the USA, Brazil, Jamaica, the Dominican Republic and Surinam. This is in contrast to northern Europe, Japan and Oceania where there are few people of African descent and little ay antigen. In the United States where about 10% (ref. 16) of the population is considered to be of African descent, 15% of the carriers are ay[17]; while in the Dominican Republic where 85% of the people have some African admixture[18], 42% of the Australia antigen is ayw^{+} d^{-}. This hypothesis could be further tested by correlating subtype data with other biological data (blood and serum groups) and linguistic, archaeological and cultural information concerning human migrations. An Au subtype marker would be unique among known biological markers since it behaves as a unit and is passed from mother to child unaltered. In contrast, inheritable human biological markers are subject to Mendelian segregation and the resulting phenotypes can change rapidly from generation to generation.

Two United States chronic carriers were found to have w^{-} antigen. They had both been in Vietnam and were presumed to have acquired their exotic subtype in Asia where w^{-} is more common. We have tested a total of 318 Au samples from both patients and asymptomatic carriers in the United States and all except those two have had the w determinant. It is probable that some veterans of the Pacific theatre returned to the United States carrying ad^{+} wy^{-} at the end of the Second World War. This subtype has not spread in the United States population to any measurable extent. This is compatible with the assumption that maternal transmission is the major mechanism for preserving an introduced subtype in a new environment.

South Central Bougainville is unusual in that there are seven different Au subtypes. It is unlikely that this diversity could be due to chance. The diversity could be related to the fact that Bougainville is located between Australia where the subtype is entirely ayw^{+} d^{-} and Oceania where the complementary subtype ad^{+} wy^{-} occurs frequently. In areas such as Bougainville two subtypes could meet and recombine by a mechanism similar to crossover which may occur in a doubly infected host, either human, animal, or arthropod. For example, if ayw^{+} d^{-} and ad^{+} wy^{-} agents coexist in the same host it is possible that they could recombine and yield four types of Australia antigen; the original ayw^{+} d^{-} and ad^{+} wy^{-}, as well as ay^{+} wd^{-} and adw^{+} y^{-} recombinations. All of these do in fact exist in Bougainville and have not been found together in other locations.

This work was supported by US Public Health Service grants and by an appropriation from the Commonwealth of Pennsylvania. We thank Drs J. Byrne, M. Goldfield, A. Prince and S. Hadziyannis for the antisera used in these studies, and all the investigators who contributed antigen samples.

Silent Maternal Transmission of Australia Antigen

CHRONIC asymptomatic carriers of Australia antigen (Au, hepatitis B antigen, HBAg, HAA and so on) are found in human populations throughout the world and they constitute an important reservoir for the maintenance of the infectious agent. Here we provide evidence which, in combination with previous data, suggests that an important mechanism for the establishment of these carriers is through the 'silent' (that is, without illness) transmission of chronic infections from generation to generation through the maternal line.

There have been several studies related to mothers with Australia antigen and their children. We analysed 109 completed or partially completed families, from five groups [Cebu, Bougainville, Lau and Baegu speaking areas of Malaita, and Sardinian[1] families from Turin]. There was a much higher frequency of Au in the offspring of matings in which the mothers were asymptomatic carriers of Au and the fathers were not, than in matings in which the fathers were carriers and the mothers were not (for all the families combined $P=0.55\times10^{-10}$ (ref. 2). Okochi and his colleagues found that of twelve children born to Japanese mothers who were asymptomatic carriers of Au, seven children became carriers within the first 6 months of life[3]. Papaevangelou found that of eleven asymptomatic Greek mothers who had Au, two had babies who developed the antigen at 6 and 14 months, respectively. The antigen did not persist in these infants (G. Papaevangelou, personal communication). Turner *et al.* made a careful documentation of transmission of antigen from a mother with hepatitis to her infant[4]. Subsequently, the infants of five mothers with Australia antigen positive hepatitis were studied and four were found to be carriers of the antigen without clinical signs of hepatitis[5].

In a larger study of mothers living in California who had Australia antigenaemia during pregnancy, or within two months of the birth of their children, Schweitzer and his colleagues found a significant incidence of vertical transmission. Of twenty-three women who had hepatitis, twelve gave birth to infants who developed Australia antigenaemia, some of which began, not at delivery, but within weeks or months afterwards[6]. In each tested instance the babies had the same subtype antigen as their mothers[7]. The children did not have signs of hepatitis other than mild elevations of serum glutamic pyruvic transaminase (SGPT). Their development was normal although the antigenaemia has persisted for up to 23 months. Of fourteen mothers in this series who were chronic antigen carriers one gave birth to a baby who became a chronic carrier. The frequency of transmission from asymptomatic mothers varies in different locations. In contrast to Japan (7/12), Greece (2/11) and California (1/14), in Denmark[8] none of the babies of eighty-one carrier mothers became positive, and in Pakistan one out of eighteen infants of asymptomatic carrier mothers developed the antigen[9]. These studies indicate that Au transmission from mothers with hepatitis is common and in some places maternal transmission from chronic carriers does occur.

The source of Au infection sometimes can be identified by immunological studies. The surface of the antigen is a composite of determinants which are immunologically distinct[10–15]. Persons infected with material containing Au of a certain immunological combination, or subtypes, will develop those subtypes[16]. The same subtype persists in both hepatitis patients and chronic carriers for as long as they have the antigen, with rare exceptions[17,18]. We have used immunological subtyping to study relationships between Au carried by different members of the same family.

The sera used in this study were collected together with pedigrees in eighteen villages in south central Bougainville[19]. They represented 85% of the healthy residents over the age of 2 yr. It was assumed that asymptomatic people with antigenaemia were chronic carriers. There was an Au carrier rate of 10.2% on Bougainville and family clustering had been observed in the initial testing of these sera. The distribution of Au had previously been subjected to segregation analysis which was compatible with autosomal recessive inheritance[19]. The observed family clustering could also be explained by intrafamily transmission of an infectious agent or maternal transmission as suggested by Turner *et al.*[4]. If this were true, then all members of a family should have the same subtype. The presence of multiple subtypes in the same family would rule against the family infection hypothesis. Sera for testing were selected from families with more than one antigen carrier so that a comparison between family members could be made.

The subtyping was done by immunodiffusion in a standard seven-hole pattern cut in 1.1% agarose in veronal buffer, *p*H 8.2 (ref. 20). In preliminary testing for d and w the antiserum was put in the centre well and a control Au which carried the determinant complementary to the antiserum was put in the top and bottom wells. If a smooth line of identity was formed between the control antigen and the test antigen the test antigen was scored as positive for the determinant in question. If a spur was formed it was considered negative for the determinant. Absorbed antiserum was used to test for determinant y. Serum from a chimpanzee immunised with Au of subtype aywx was absorbed with adwx+y− antigen, leaving anti-y in the antiserum. This was used with a y positive antigen control. Antigens giving a line of identity were considered positive; those giving no line, negative.

A few unusual sera carried neither d nor y. All such d− y− antigens were retested with different dilutions of antisera and an additional anti-ad and anti-ay sera. All plates were dried and stained with azocarmine for better visualisation of precipitin lines.

Table 1 Australia Antigen Subtypes Found in Eighteen Villages on Bougainville

		Subtype D (d+y−)		Subtype Y (d−y+)		Subtype A (d−y−)		Subtype DY (d+y+)	
Village	Total Au.	w+	w−	w+	w−	w+	w−	w+	w−
1	18	0	3	10	4	1	0	0	0
2	4	1	1	2	0	0	0	0	0
3	3	0	2	0	1	0	0	0	0
4	5	0	1	3	1	0	0	0	0
5	5	0	4	0	1	0	0	0	0
6	14	0	9	5	0	0	0	0	0

16	1	0	0	0	0	0	0	1	0
17	20	1	11	0	8	0	0	0	0
18	20	1	7	6	6	0	0	0	0
	174	17	75	42	35	1	2	2	0

All possible combinations of determinants d, y and w except d+y+w− (Table 1) were found in this population. Of the 174 Au samples typed, two contained both d and y. This is a rare event and has not been reported before in normal people who have not received transfusions. These determinants seemed to be on the same particle (S. Mazzur and S. Burgert, personal communication).

Villages 2, 11, 13 and 16 did not contain families in which there were more than one member with Au. The data from families in the remaining villages which have more than one member with antigen are shown in Table 2. Of the thirty-two families tested there were eleven families in which two different combinations of antigens were segregating.

Asymptomatic carriers living in the same household can have different subtypes of Australia antigen (Table 2). This means that these carriers have not been infected by each other nor from the same source. This rules out simple household infection or maternal transmission as an explanation for all the observed family clustering in these families.

A special case of family infection does, however, seem to occur. In families where the mother was an asymptomatic carrier, the twenty-two children who were carriers with a single exception had the same subtype as their mother. Among the twelve families where the mother was positive, one had mixed subtypes, while among the twenty families in which the mother did not have Au, ten families had antigen of different subtypes. These reflected the subtypes in the general population of the village. Among the six families in which the father was positive, there were mixed subtypes in four of the families. Children with Au from families where either the mother but not the father, or the father but not the mother, carried the antigen were compared using Fisher's exact test (two-tailed). The difference in distribution was significant ($P=0.006$). When the families in which either parent was not available for testing were excluded from the analysis, the differences were still significant ($P=0.007$). The same test was used to compare the number of siblings of matching subtype in families with Au carrier and Au negative mothers. This difference was significant ($P=0.005$).

Table 2 Distribution of Australia Antigen Subtypes in Families where More than One Member has the Antigen in the Blood

Village	Father	Mother	Sibs

* Indicates families with mixed subtypes. NA indicates not available.
† Insufficient amount to test for y.

These data indicate that vertical transmission from asymptomatic mothers to their asymptomatic children occurs in this environment. Horizontal transmission with the production of carriers must also occur within this population since maternal transmission cannot account for all of the observed carriers.

Genetic predisposition to the chronic asymptomatic carrier state has been proposed by Blumberg[19,21] and confirmed by Ceppellini[1] on the basis of segregation analysis of the distribution of Australia antigen in several populations. Segregation analysis of the distribution of Au in the same Bougainville sera which were used in this study revealed the segregation pattern expected of autosomal recessive inheritance. The vertical transmission reported in this communication is compatible with the genetic hypothesis since the genetic analysis was applied also to matings in which neither parent was a carrier of Au. There would be no maternal effect in these families. There is not an occult maternal effect due to undetected levels of antigen in the mothers' serum because the subtypes of the children do not, in general, match each other as they would in such a case.

Women who become Au carriers by virtue of genetic susceptibility can be expected to transmit the antigen to some of their children whether or not the children are homozygous for the postulated recessive Au susceptibility gene. Thus, a new maternal transmission line can be established from a genetically susceptible woman whose own mother was not a carrier provided the susceptible woman is exposed to infection. The interaction of the genetic predisposition to the carrier state and maternal transmission could be an important source of Au carriers. Further, the interaction of these two mechanisms, one of which is dependent on the survival and reproduction of women who are carriers, would provide a very rapid amplification of the number of carriers of Au in an environment where such a carrier state is advantageous. Such a selective advantage has been suggested by Blumberg *et al.*[22].

Not all children of mothers who are Au carriers become carriers themselves. There are factors, either genetic or environmental or both, which influence the outcome of the maternal-child relationship. We suggest that other, perhaps undiscovered, human pathogens survive by the mechanisms

described here and are usually expressed as disease when passed horizontally or after long incubation. Techniques developed through the study of Australia antigen as well as epidemiological patterns disclosed by these studies could serve as models for the investigation of these agents. It has been suggested that other infectious agents may exist that have properties similar to Australia antigen. These have been termed Icrons[23].

Silent maternal transmission with the production of asymptomatic carriers seems to provide a reliable mechanism for virus survival particularly in small populations where the number of new susceptible individuals is limited. The carrier state maintains the infectious agent over long periods of time and the maternal-child interaction provides exposure of new susceptibles. In contrast, many acute viral infections spread quickly, exhaust the availability of susceptible hosts and disappear from isolated populations.

This work was supported by United States Public Health Service grants from the National Institutes of Health and by an appropriation from the Commonwealth of Pennsylvania. We thank Drs J. Byrne, M. Goldfield, A. Prince and S. Hadziyannis for the antisera used in these studies as well as all who contributed antigen samples to the study.

Lethal Effect of Near-ultraviolet Irradiation on Mammalian Cells in Culture

THE lethal and mutagenic effects of ultraviolet light of wavelength below 300 nm on bacterial and mammalian cells have been the subject of many research projects, and several laboratories are investigating the action of near-ultraviolet irradiation provided by black light (300 to 420 nm) on bacterial cells[1]. There are, however, only a few studies on the effect of black light (near-ultraviolet) on mammalian cells[2,3]. Several laboratories have reported effects of both visible fluorescent light, which does produce a significant amount of emission in the near-ultraviolet region, and black light on mammalian cells after the incorporation of bromodeoxyuridine (BUdR) into the cell nucleic acid[3–7].

Experiments were initiated in this laboratory to study the effect of black light on mammalian cells in culture. Here we report that when mammalian cells in tissue culture medium were irradiated with black light, the cells were killed both reproductively (as evidenced by measuring clone-forming ability) and physiologically (as evidenced by staining with trypan blue dye).

The cells used were mouse 3T6 (ref. 8), Chinese hamster V79 clone 753-B-3M (ref. 9) and human D98/AH$_2$ (ref. 10). The cells were cultured in Dulbecco's modification of Eagle's medium[11] supplemented with 10% calf serum but without addition of antibiotics. The CO$_2$ tension for cell growth and light exposure was held at 10%. The light sources used were two General Electric F15T8 BLB integral filter black light tubes with emission in the 290 to 420 nm range peaking at 365 nm[12]. Light exposures were carried out in covered Falcon 3002 60 mm dishes containing 3.5 ml medium with no phenol red or serum. The culture dish lids excluded irradiation below 300 nm[13]. Exposure intensity was 5 μW mm^{-2} on the culture dish lid and 4 μW mm^{-2} at the cell surface as measured by a Blak-ray meter J-221 (Ultraviolet Products, Inc.). Temperature was monitored and regulated to avoid any effect due to heating by the light source.

When mouse 3T6 fibroblast cells plated at 120 and 10^4 cells per 60 mm dish were exposed to the BLB lights, 90% and 99% of the cells lost the ability to form clones during exposure times of 90 and 130 min respectively (Fig. 1*a*). The plating efficiency decreased less rapidly if the initial inoculum was 10^5 cells. When 10^6 cells were plated, no appreciable loss of plating efficiency was detected.

Similar density-dependent loss of plating efficiency was found with Chinese hamster V79 and human D98/AH$_2$ cells (Fig. 1*b* and *c*). V79 cells were inactivated at a slower rate than 3T6 cells when 120 and 10^4 cells were plated per dish. No loss of plating efficiency was detected in dishes plated with 10^5 or 10^6 cells. D98/AH$_2$ cells were as sensitive to BLB as 3T6 except that the loss of plating efficiency was more rapid when 120 cells were plated per dish.

It seems that the final slopes of the inactivation curves, where loss of plating efficiency did occur, were similar for each cell line. The shoulders in the curves became more pronounced as cell density was increased.

The above experiments measured the loss of the cells' ability to form clones, that is, the amount of reproductive death. In order to ascertain whether black light killed the cells physiologically as well, we measured the ability of the cells to exclude the dye trypan blue which stains physiologically non-viable cells. Dishes containing 3,000 cells each were exposed to black light at 4 μW mm^{-2} for 90 min and returned to a dark incubator. At various intervals after the exposure, trypan blue was added and the number of cells without dye was counted.

When 3T6 cells were used, approximately 90% of the cells lost their ability to exclude the dye during a 2 to 4 h period (Fig. 2*a*). For V79 cells the loss occurred between 6 to 8 h

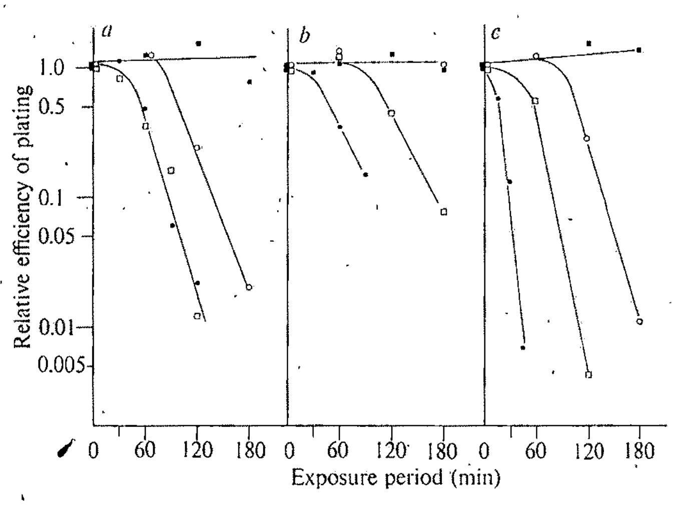

Fig. 1 The cells were trypsinised and plated in medium containing serum, but no phenol red, 18 h before exposure to 4 μW mm^{-2} black light. Twenty minutes prior to irradiation, the medium was removed and replaced with medium free of both phenol red and serum. The dishes were placed in the exposure chamber under 10% CO_2 for 20 min before the light was turned on. At various intervals dishes containing 120 cells were removed from the light and medium was replaced with fresh medium with serum. Dishes with 10^4, 10^5 and 10^6 cells were subcultured and diluted into dishes containing fresh medium with serum. The subculture procedure itself does not alter the viability of the cells. All dishes were incubated at 37° C for 7 to 10 d in the dark. The dishes were then stained with haematoxylin and colonies counted. The result is expressed in relative efficiency of plating, or the number of colonies formed divided by number of cells inoculated initially, with the zero time value set equal to 1. ■, 10^6; ○, 10^5; □, 10^4; ●, 120 cells plated per 60 mm dish and exposed to black light. *a*, 3T6 cells; *b*, V79 cells; *c*, D98/AH_2 cells.

(Fig. 2*b*). We expected that at least 99% of the 3,000 D98/AH_2 cells would be killed after the 90-min exposure period (Fig. 1*c*) and the same proportion of cells (>99%) actually did lose the ability to exclude trypan blue within a 10-h period after exposure to black light (Fig. 2*c*).

Our results showed that black light killed human, mouse and Chinese hamster cells in Dulbecco's medium. Human and mouse cells were killed when up to 10^5 cells were plated per 60 mm tissue culture dish, and Chinese hamster cells were killed at densities up to 10^4 cells per dish. The killing effect was density dependent. When 10^6 cells were plated, no decrease in viability was observed.

At the molecular level, the effects of far-ultraviolet (< 300 nm) and near-ultraviolet (300 to 420 nm) on biological systems are quite different[14]. Far-ultraviolet leads to lethality by directly altering the DNA through dimer formation. Near-ultraviolet, at the dosage used in these experiments, does not produce dimers in bacterial systems[1]. A possible chromophore may be present in the respiratory chain which absorbs energy in wavelengths above 300 nm[14]. Recombinationless bacterial mutants are highly sensitive to near-ultraviolet, suggesting that DNA may be an indirect target of the action of near-ultraviolet[1]. One cannot rule out other possible chromophores which may act indirectly to produce the results reported here. It is also conceivable that toxic photoproducts are produced in the medium which when taken up by the cells leads to lethality. Our finding that the cell killing effect is density dependent could be due to the fact that when more cells were present, the amount of photoproducts absorbed by each cell was correspondingly less. This possibility is compatible with the shoulders observed in the inactivation curves (Fig. 1). No cell killing would be observed until the increase in toxic products was adequate to saturate each cell to a level sufficient to inactivate it. In a separate manuscript (unpublished) we shall show that after components of tissue culture medium are exposed to near-ultraviolet, toxic photoproducts are formed which are primarily responsible for the type of mammalian cell inactivation as reported here.

The black light tubes used in this study emit in the 290 to 420 nm region. Although the peak of emission is relatively sharp[12], the responsible wavelengths for the killing observed here remain uncertain. Experiments are currently in progress with monochromatic light to determine the wavelengths which are most effective.

A better understanding of the effect of light irradiation in the 300 to 420 nm region on mammalian cells is needed. Visible fluorescent light, which illuminates virtually every laboratory, contains a significant amount of emission in this region. Puck and Kao[4] devised a technique utilising BUdR and visible fluorescent light for the selection of auxotrophic Chinese hamster mutant cells after treatment with mutagens. Chu *et al.*[3] reported that such selective techniques had highly mutagenic action. Visible fluorescent light increased the amount of polyoma virus induction nine-fold[7]. The near-ultraviolet region of visible fluorescent light can kill mammalian cells in culture (unpublished). The finding that near-ultraviolet produced by black light can effectively kill mammalian cells in tissue culture medium, as reported here, further emphasises the fact that considerable caution should be exercised in experiments involving the irradiation of mammalian cells with visible fluorescent light or black light. In addition, since black light is widely used outside the laboratory, the possible mutagenic and carcinogenic action of 300 to 420 nm radiation also needs to be carefully examined.

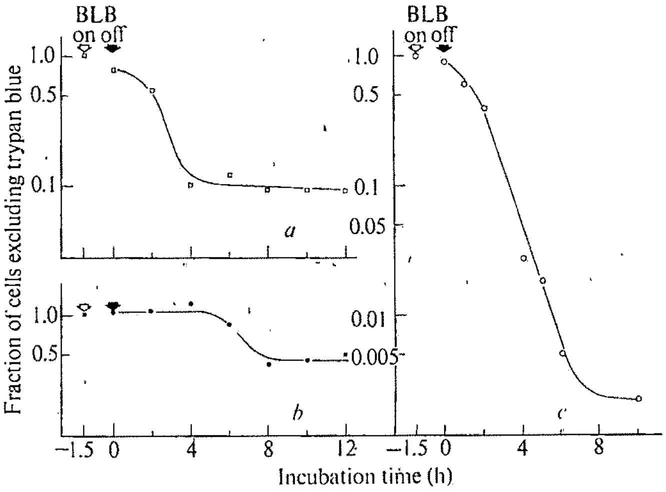

Fig. 2 3,000 cells were plated per 60 mm dish and exposed to 4 μW mm^{-2} black light as in Fig. 1. The cells were exposed to light for 90 min before being returned to incubation in the dark. At various intervals, trypan blue (0.5%) was added to the dishes for 5–7 min and the number of cells containing no dye was counted under ×40 magnification. Symbols as in Fig. 1; *a*, 3T6 cells; *b*, V79 cells; *c*, D98/AH_2 cells.

We thank Dr H Green for 3T6 and D98/AH_2 cells, Dr M. M. Elkind for V79 cells, Dr A. Burdick for advice on the use of trypan blue, Dr A. Eisenstark for encouragement and reviewing the manuscript. This work was supported by grants from the American Cancer Society and the National Science Foundation, and by a Public Health Service Research Career Development Award from the National Institute of General Medical Sciences to R. J. W.

Control of Cell Surface Topography

According to the fluid mosaic model of membrane structure[1], surface proteins are free to diffuse in a lipid matrix and thus to assume a random or homogenous distribution over the cell surface. In support of this model it has been shown that the distribution of glycoprotein receptors for the plant lectin concanavalin A (con A) is random in all cell types studied. In a variety of living systems it has also become clear that surface elements can be induced by exogenous agents to assume a non-random or heterogeneous distribution; for example, in virus transformed cells con A induces a clustering of con A binding sites. Recently, we and others have shown that cellular components sensitive to colchicine alkaloids (microtubules and perhaps other structures with similar pharmacological specificities) can affect the topography of certain surface elements. We shall review here the experimental evidence for systems in which topographical heterogeneity of specific surface elements (lectin binding sites and membrane transport carriers) can be induced and can be altered by colchicine. We shall then advance a general hypothesis involving specific interactions between surface proteins and intracellular colchicine binding proteins (CBP), which rationalises some apparent contradictions in this evidence and which indicates a molecular process at the level of the plasma membrane by which cells may respond to extracellular substances.

(1) When virus transformed fibroblasts are fixed with paraformaldehyde, the distribution of con A binding sites is random, as it is in non-transformed cells and as predicted by the fluid mosaic model. When con A is adsorbed to cells before fixation the distribution of con A binding sites in non-transformed cells is, however, still random, whereas in transformed cells the binding sites are gathered into clusters[2]. These clusters are withdrawn from the edges of the cell but otherwise are themselves disperse (T. E. U., R. D. B., J. Z. Borysenko, and M. J. Karnovsky, unpublished). Incubation of transformed cells with 1 μM colchicine before con A does not affect the formation of clusters, but the clusters are now loosely grouped into a large circumnuclear surface aggregate. These data suggest an enhanced mobility of con A binding sites after transformation which is further increased by alkaloid treatment.

(2) Treatment of lymphocytes with low concentrations of con A at 37° C leads to movement of con A binding sites into large aggregates known as "caps". At high concentrations of con A, however, no caps are formed during incubation at 37° C[3,4]. Thus, con A binding sites seem to be immobilised after addition of the high concentrations of lectin. In parallel experiments where lymphocytes are cooled to 4° C (presumably dissolving microtubules) or treated with colchicine, con A leads to capping even at high concentrations[5], indicating an increased mobility of con A binding site clusters in these cells.

(3) During phagocytosis particles are enveloped by cytoplasmic membrane which is then withdrawn into membrane-bound intracellular vesicles. Under suitable conditions more than 50% of the surface of polymorphonuclear leukocytes or alveolar macrophages can be internalised in this fashion. Using initial rates of purine and amino acid transport to assay the numbers of specific carrier proteins in the membrane, it has been shown that the same number of transport carriers are present before and after removal of a high proportion of the plasma membrane by phagocytic ingestion of latex beads[6]. Other experiments[6] rule out the insertion of new carriers into the surface membrane. This preservation of transport sites indicates their separation into a topographically distinct area which does not undergo internalisation. When leukocytes are pretreated with colchicine, however, phagocytosis leads to a decrease in transport rate which parallels the degree of membrane internalisation[7]. Thus, it seems that the forces which exclude transport carriers from phagocytic areas do not operate after colchicine treatment.

(4) Morphological studies of non-phagocytosing leukocytes show that con A binding sites are distributed randomly on the cell surface (J. M. O., R. D. B., J. Z. Borysenko, and M. J. Karnovsky, unpublished). When con A and *Ricinus communis* agglutinin (RCA) receptors are titrated after the phagocytic ingestion of droplets of a paraffin oil emulsion it can, however, be shown that the specific activity of surface binding sites (defined as μg lectin bound per 100 μg membrane protein) is reduced by 40–60% (the reverse of case (3) above for transport proteins[8]). Thus, during phagocytosis lectin binding sites are removed from the surface, apparently by concentration in the regions undergoing internalisation. After colchicine treatment, the removal of specific populations of lectin binding from the surface is greatly reduced, indicating an uncoupling of the process which links the concentrative movement of con A binding sites with the internalisation of phagocytic particles[9].

The effects of colchicine on (1) and (2) as compared with (3) and (4) on movement of specific surface elements are in apparent contradiction. Thus, movement of con A binding site clusters induced by con A, as in cap formation, occurs only after colchicine treatment whereas the concentrative movements of transport carriers and lectin binding sites induced by phagocytosis do not occur after colchicine. This paradox can be resolved simply by the following hypothesis: for cross-linking by con A (1) and (2), clusters of con A binding sites must have sufficient mobility to be approximated by the lectin. This requires release from cellular restraints which tend to separate and/or direct them. Colchicine abolishes these restraints. On the other hand, the directed movements which occur during phagocytosis ((3) and (4)) require the attachment of receptors (or transport proteins) to these restraining cellular structures which themselves direct specific movement. Colchicine abolishes these attachments and thus the cell-directed movement of con A binding sites into (and probably certain transport proteins out of) membrane internalised by phagocytosis. Thus, in all cases colchicine abolishes the attachment of membrane proteins to mobile cellular structures, permitting their association by exogenous cross-linking agents on the one hand, but abolishing cell-directed movements on the other.

What is the nature of these colchicine-sensitive linking structures? In the cases so far examined their pharmacological specificity parallels that of microtubular proteins: sensitivity to colchicine, colcemid, and the chemically unrelated vinblastine, and insensitivity to the photochemical derivative, lumicolchicine. Operationally, therefore, the 'linkage element' behaves like a microtubular protein, but it is not yet proven that colchicine treatment alters membrane properties through its interaction with structures identified morphologically as microtubules. It is possible that contractile structures, perhaps microfilaments, may interact with these colchicine-sensitive elements in order to facilitate movements of the surface proteins.

Our hypothesis represents a synthesis of the fluid mosaic theory, which suggests a random distribution of surface proteins, with data from several experimental systems in which topographical heterogeneity can be produced. It is proposed that con A-receptor complexes can be aggregated into large caps if the receptors are not restrained in their movement patterns by colchicine-sensitive elements; and in addition that movement of con A binding sites can be directed into local regions by exogenous agents such as phagocytic particles if these linkage elements are intact, that is, cell-directed movements of con A binding sites and cross-linking by bound con A are in this sense mutually exclusive. Experiments which test this theory may allow more precise definition of the mechanisms by which changes in cell surface topography can be directed by intrinsic cellular structures in response to extrinsic forces.

Immune Complexes induce Selective Release of Lysosomal Hydrolases from Macrophages

IMMUNE complexes contribute to tissue damage in a variety of experimental and human diseases. Immune complexes induce arthritis[1] and nephritis[2,3] in laboratory animals while lupus glomerulonephritis[4] and possibly rheumatoid arthritis[5] are examples of their effects in man. The mechanisms by which damage is initiated and perpetuated are poorly understood. In the acute stage of inflammation resulting from immune complexes many granulocytes are present. These cells have abundant lysosomes rich in acid hydrolases which when released can degrade various tissue components. Enzyme release may result from cell death or exocytosis of granules from viable cells. Henson[6] and others[7,8] have shown that granulocytes exposed to immune complexes *in vitro* release lysosomal enzymes while remaining viable, and presumably the same happens in Arthus reactions *in vivo*.

After the initial phase of immune complex-induced tissue injury, neutrophils are no longer prominent and other cells may play a role in the continuation of the inflammation.

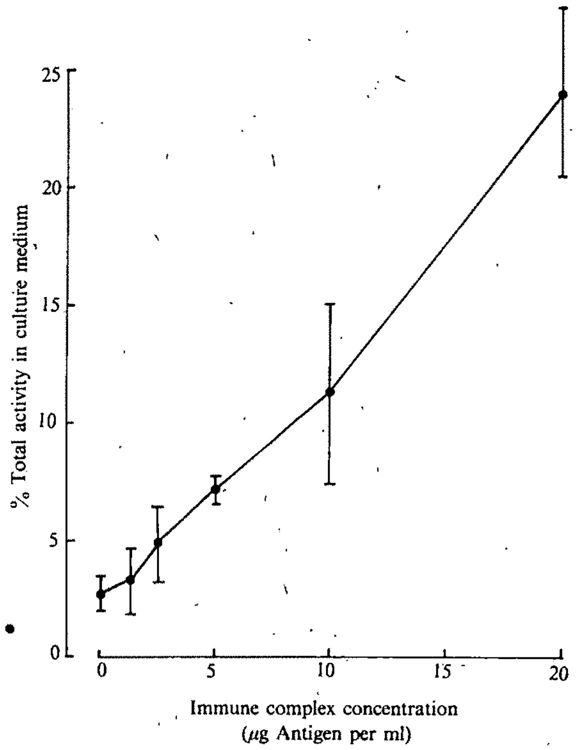

Fig. 1 The release of β-glucuronidase from macrophages exposed to increasing concentrations of immune complexes. Macrophages were collected by peritoneal lavage of outbred Swiss mice (LACA strain, SACI, London Road, Braintree, Essex) with 5 ml M199 (Grand Island Biological Co., Grand Island, New York)+10% swine serum (Biocult Laboratories, Glasgow). 2 to 2.5×10^6 cells were plated in 48 mm plastic Petri dishes (Nunc, Jobling Laboratories Division, Stone, Staffordshire). After 30 min the cell sheets were washed four times with phosphate-buffered saline and then cultured in M199 +10% swine serum at 37° C in a 5% CO_2 in air atmosphere for 48 h. Immune complexes were formed by interacting ferritin (Miles Laboratories) and rabbit anti-ferritin serum (Miles Laboratories). The point of equivalence was determined by quantitative precipitation[16]. The cells were exposed to increasing amounts of immune complexes for 6 h. At this time the culture medium was removed, centrifuged at 1,000 r.p.m. for 10 min in a No. 59548 swing-out head of a Mistral 6L centrifuge to pellet detached cells. The cell sheet was washed once with 0.9% NaCl (w/v) and then removed in 2.5 ml 0.9% NaCl (w/v) containing 0.1% Triton X-100 (w/v). All fractions were assayed for β-glucuronidase activity by the method of Talalay *et al.*[17]. Each value represents the mean ± s.d. of four separate plates.

Phagocytic cells such as blood-borne monocytes, tissue macrophages, mesangial cells of the kidney and A cells of synovium are present at sites of tissue damage in chronic inflammation associated with immune complexes. Moreover, mononuclear phagocytic cells are known to interact with immune complexes. Human monocytes have receptors for the Fc portions of IgG1 and IgG3[9]. Mouse peritoneal macrophages and rabbit alveolar macrophages take up immune complexes[10,11], as do renal mesangial cells[12] and A cells of rheumatoid synovium[1]. The interaction of these phagocytic cells with immune complexes may also result in tissue damage. These cells contain lysosomal enzymes which can not only digest immune complexes but degrade connective tissue constituents when released from the cells[13]. Lysosomal hydrolases may again be released from macrophages by cell death[14] or selectively discharged from viable cells (ref. 15 and P. D., R. Page, and A. C. A., unpublished). It has already been reported that macrophages take up and digest immune complexes *in vitro*[10]. We now present evidence that this process is accompanied by a selective release of macrophage hydrolases from viable cells into the culture medium.

Figure 1 shows the effect of increasing concentrations of an immune complex on the release of lysosomal enzymes from macrophages. After 6 h incubation in medium containing 5 $\mu g\ ml^{-1}$ of immune complex, the concentration of β-glucuronidase in the medium is significantly greater than controls ($P<0.01$). There is a dose-dependent release of enzyme rising to 24.0±3.5% with 20 $\mu g\ ml^{-1}$ of immune complex.

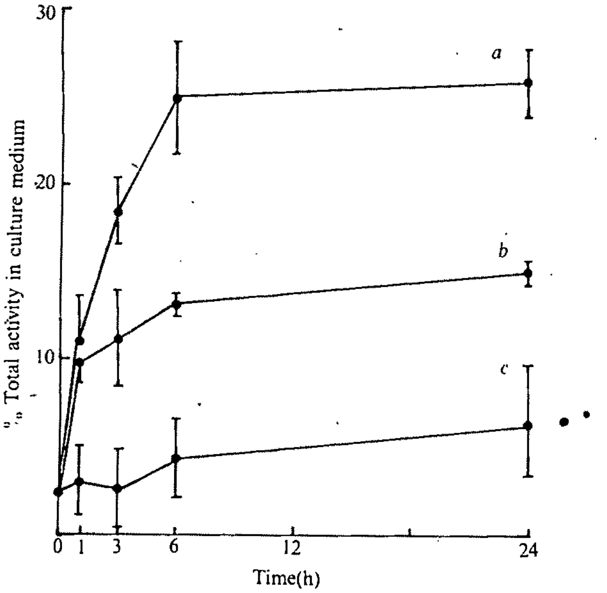

Fig. 2 The time dependence of macrophage β-glucuronidase release induced by immune complexes. The experiment was carried out in similar conditions to those described in Fig. 1 except that immune complexes were formed at equivalence from bovine serum albumin, Cohn Fraction V (Sigma Chemical Co., London) and rabbit anti-bovine serum albumin (BSA–anti-BSA). The latter was prepared by intramuscular inoculation of New Zealand White rabbits with 15 mg of antigen followed 3 weeks later by injection of 5 mg antigen intravenously. The animals were bled 10 d later. Each value represents the mean ±s.d. of four separate plates. *a*, 20 $\mu g\ ml^{-1}$; *b*, 10 $\mu g\ ml^{-1}$; *c*, control.

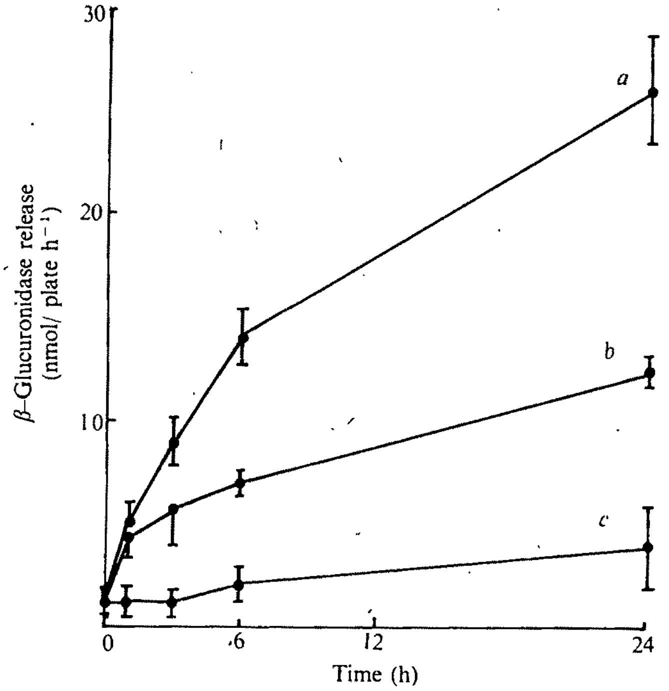

Fig. 3 The release of increasing amounts of β-glucuronidase from macrophages exposed to immune complexes for 24 h. Experimental conditions were identical to those described in Fig. 2. Each point represents the mean ±s.d. of four separate plates. *a*, 20 $\mu g\ ml^{-1}$; *b*, 10 $\mu g\ ml^{-1}$; *c*, control.

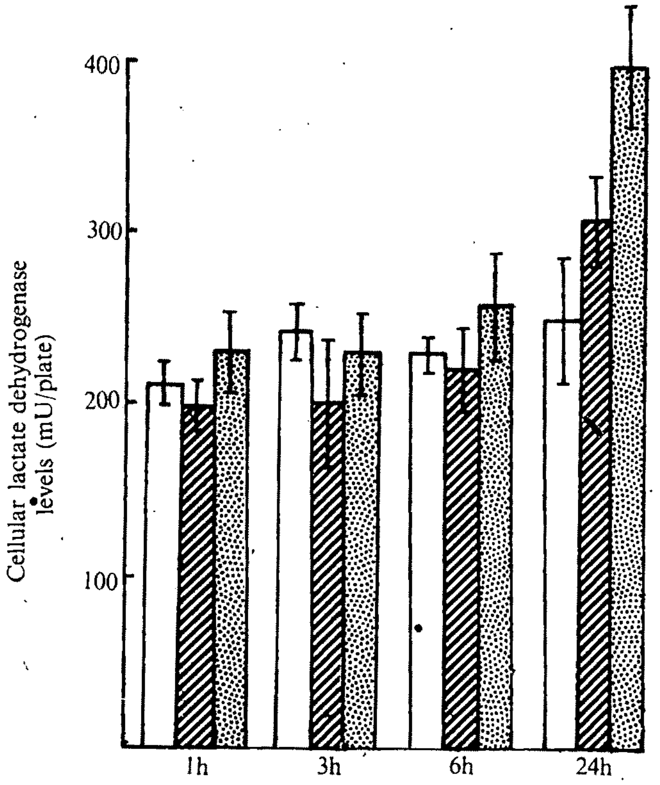

Fig. 4 The levels of lactate dehydrogenase (LDH) in macrophages exposed to immune complexes. Experimental conditions were identical to those described in Fig. 2. LDH was assayed using Biochemical Test Combination LDH-UV (Boehringer Corp. (London) Ltd). □, Control; ▨, immune complexes (20 $\mu g\ ml^{-1}$); ▒, immune complexes (10 $\mu g\ ml^{-1}$).

Release of the lysosomal enzyme is time dependent. In Fig. 2, the release of β-glucuronidase into the culture medium over 24 h with 10 $\mu g\ ml^{-1}$ and 20 $\mu g\ ml^{-1}$ of immune complex is shown. Release is demonstrable 1 h after contact and continues over the subsequent 23 h. Although the percentage of total β-glucuronidase activity in the culture medium plateaus after 6 h, the absolute amount continues to increase because of enzyme synthesis by the cells (Fig. 3). This indicates that depletion of intracellular acid hydrolase may act as a signal for increased enzyme synthesis.

Figure 4 shows that at no time during the 24 h period is there a significant decrease in cellular lactate dehydrogenase levels, compared with controls, of cultures exposed to immune complex ($P>0.01$) in all instances. Moreover, cultures exposed to 10 $\mu g\ ml^{-1}$ of immune complex for 24 h show a statistically significant ($P<0.01$) increase in cellular LDH level compared with its control.

For the sake of brevity we have only presented data for β-glucuronidase, but a similar pattern of selective release has been demonstrated for other lysosomal hydrolases such as N-acetyl-β-D-glucosaminidase and β-galactosidase; this information will be published in detail elsewhere.

It is now clear that both granulocytes and macrophages, phagocytic cells associated with acute and chronic inflammation respectively, can selectively release lysosomal hydrolases with no detectable loss of viability. This phenomenon may provide an explanation for the ability of macrophages to cause tissue damage and degradation at sites of chronic inflammation while retaining their viability over prolonged periods of time. This interpretation is supported by evidence that other agents inducing chronic inflammation, such as Group A streptococcal cell walls, also cause selective release of lysosomal hydrolases from viable macrophages *in vitro* (P. D., R. Page, and A. C. A., unpublished).

As immune complexes and macrophages are both present in the joints of patients with rheumatoid arthritis, release of macrophage hydrolases could play an important part in degradation of cartilage and other connective tissue changes observed in this disease. The role of immune complexes and macrophages in other chronic inflammatory conditions also deserves further study.

Vitamin A Deficiency enhances Binding of Benzo(*a*)pyrene to Tracheal Epithelial DNA

THE relationship between carcinogen action and the state of cellular differentiation in target tissues is still unclear. Vitamin A controls the state of differentiation in many epithelial tissues[1], including those of the respiratory tract[2,3]. Vitamin A can also modify the process of carcinogenesis in many tissues; in a variety of experiments, the results obtained have often been influenced by experimental variables such as the animal species, the time and route of vitamin A administration, and the morphological type and the tissue site of tumour induced[4-10]. In the respiratory epithelium[3] vitamin A deficiency causes basal cell hyperplasia and squamous metaplasia. In order to study the possible relationship of the altered state of differentiation of respiratory epithelium to chemical carcinogenesis in this tissue, we have studied the binding of tritiated benzo(*a*)pyrene (^{3}H-BP) to DNA in tracheal epithelial cells of normal and vitamin A deficient hamsters. The binding of carcinogens to DNA has been indicated as a potentially crucial step in the carcinogenic process[11-13]. For polynuclear hydrocarbons such as benzo(*a*)pyrene, this binding is presumed to be the ultimate result of metabolism to reactive carcinogenic forms[14-16]; the extent of binding may be a measure of the carcinogenic potential towards a given tissue.

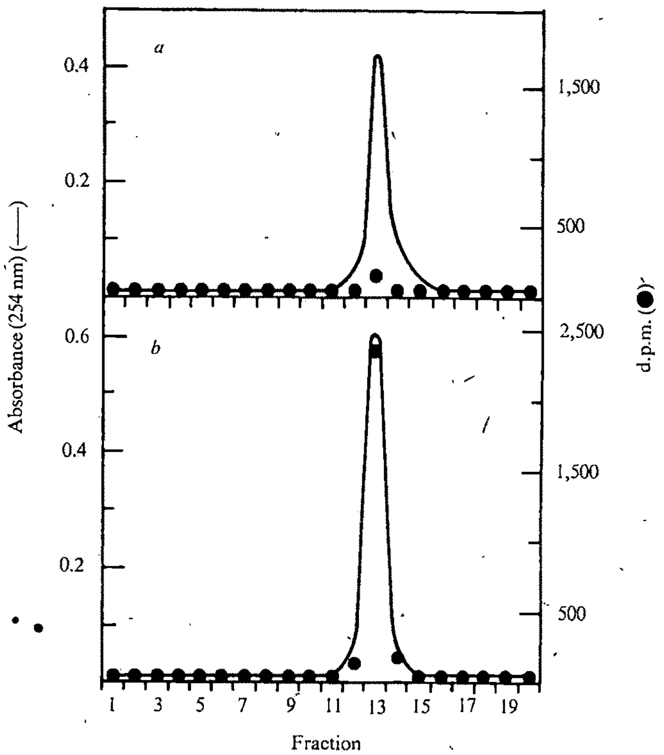

Fig. 1 CsCl gradient profiles of DNA purified from tracheal epithelium isolated from, *a*, normal and, *b*, vitamin A deficient hamsters. Isolated tracheas were maintained *in vitro* in L-15 medium containing 8.0×10^{-7} M ^{3}H-BP (20 μCi ml^{-1}, specific activity 25 Ci mmol^{-1}, Amersham-Searle). Following 3 h incubation, the tracheal epithelial cells were scraped from supporting structures and a crude preparation of DNA was obtained by phenol extraction and precipitation with 50% ethanol. The precipitate was extracted with ether, benzene, and chloroform-methanol (3 : 1), and then sequentially digested with RNase (Worthington Biochemicals) and Pronase (Calbiochem). The aqueous solution of DNA was extensively dialysed and then banded on CsCl gradients (Beckman SW56 rotor, 35,000 r.p.m., 66 h, 25° C). Gradients were fractionated into 0.2 ml portions, and absorbance and radioactivity were determined on each fraction. The absorbance of the gradient effluent was continuously monitored at 254 nm, as shown by the continuous line; radioactivity (d.p.m.) is indicated as points.

We report here the relative binding of ^{3}H-BP to tracheal epithelial DNA of vitamin A deficient and pair-fed normal hamsters under conditions in which isolated tracheas were incubated *in vitro* in the presence of ^{3}H-BP. Hamsters were made vitamin A deficient by maintenance on a vitamin A deficient diet starting at day 10–14 after birth; controls were pair-fed with the same diet supplemented with vitamin A (100 μg *all-trans* retinyl acetate, twice a week, by stomach tube)[3]. Tracheas were removed from the vitamin A deficient and pair-fed control hamsters and the isolated tracheas were incubated *in vitro* in L-15 medium containing ^{3}H-BP under conditions which preserved biochemical function and morphology[17]. Following incubation, the tracheas were washed extensively with phosphate buffered saline and the tracheal epithelial cells were scraped from supporting structures. DNA was isolated from the epithelial cells, and the purified DNA was banded in CsCl gradients as previously reported[18]. The results are shown in Fig. 1 and Table 1. Substantially greater quantities of radioactivity were associated with DNA prepared from vitamin A deficient tracheas. When isolated tracheas were incubated *in vitro* in the presence of ^{3}H-BP and equimolar amounts of 7,8-benzflavone (7,8-BF), an inhibitor of the aryl hydrocarbon hydroxylase system[19,20], the binding of ^{3}H-BP to DNA was reduced (Table 1). This result strongly suggests that the extent of benzo(*a*)pyrene binding to DNA depends largely on the ability of tracheal epithelial cells to metabolise it. The extent to which the increased binding of benzo(*a*)-pyrene to tracheal DNA in vitamin A deficient animals depends on altered activity of microsomal aryl hydrocarbon hydroxylase enzymes or on other altered cellular conditions, such as altered cellular membrane permeability or increased DNA synthesis, has yet to be established.

Table 1 Specific Activity of ^{3}H-BP bound to DNA of Tracheal Epithelial Cells during *in vitro* Incubation

Vitamin A status of animals	Addition to incubation medium ^{3}H-BP Exp. 1	^{3}H-BP Exp. 2	^{3}H-BP and 7,8-BF Exp. 2
Normal	6.0	13.4	1.3
Deficient	25.0	76.2	1.3

The data are expressed as d.p.m. per µg DNA. The µg of DNA and d.p.m. was determined from the peak DNA fraction of CsCl gradients. For each value presented in the table, DNA was prepared from two tracheas and pooled before purification on CsCl gradients. The animals were made vitamin A deficient by maintenance on a vitamin A deficient diet, starting on day 14 after birth in Exp. 1 and on day 10 after birth in Exp. 2.

The cellular location of the increased binding of benzo(*a*)-pyrene in vitamin A deficient tracheal epithelium has recently been demonstrated by quantitative light microscope autoradiographic studies. C. C. H. *et al.* (unpublished observations), using quantitative techniques[21], have demonstrated that in vitamin A deficient tracheas there is a higher binding of ^{3}H-BP to macromolecular structures of basal cells located in squamous metaplastic areas than to basal cells located in normal areas. These studies will be reported elsewhere in full detail.

The aim of the above experiments was to study the effects of a potentially co-carcinogenic condition, namely vitamin A deficiency, on the extent of binding of benzo(*a*)-pyrene to hamster tracheal DNA. It has not yet been shown in parallel long term animal studies, however, that vitamin A deficiency determines a state of high carcinogenic susceptibility in this tissue and in this species. In an analogous *in vivo* experiment conducted on rats which had been treated with the carcinogenic hydrocarbon 3-methylcholanthrene, preliminary results suggest that there is a higher incidence or an earlier appearance of respiratory tract tumours in animals fed a diet with a subnormal vitamin A content, compared with animals maintained on a normal vitamin A diet (P. Nettesheim, personal communication). Similar results have also been reported for colonic tumour induction in rats maintained on diets with subnormal vitamin A content[22,23]. The above results suggest that determination of the extent of binding of benzo(*a*)pyrene to DNA during short term organ culture of isolated tracheas may be applicable as a method for screening potential states (or potential individuals) with increased susceptibility to respiratory carcinogenesis.

We thank Mr William R. Henderson for assistance with the pair-feeding of experimental diets.

Evidence for a Junctional Effect of Lead on Neuromuscular Function

The peripheral neuromuscular pathology of lead has been extensively described in the clinical literature, but the mechanism of lead toxicity which results in neuromuscular impairment is not known[1]. Early work attempted to locate the site of a toxic lesion in the muscle and showed changes in muscle inorganic phosphate and creatine phosphate levels after lead treatment[2,3]. Experiments on the superior cervical ganglion, however, suggested that lead affected synaptic transmission by lowering the amount of acetylcholine released on preganglionic stimulation[4]. In order to separate the effects of lead on nerve from effects on muscle we have carried out experiments using the isolated phrenic nerve-diaphragm preparation.

Male Sprague-Dawley rats, weighing 120 to 135 g, were anaesthetised and the diaphragms with both phrenic nerves attached were removed and separated into two hemidiaphragms, each with a nerve trunk attached. The nerve-muscle preparation was similar to that originally described by Bulbring[5], modified so that preparations could be stimulated separately through either the nerve or muscle. One hemidiaphragm with its phrenic nerve was exposed to lead, as lead chloride, in a range of concentrations from 1×10^{-5} M to 1×10^{-4} M. Its pair was run simultaneously as a control. (Krebs–Ringer bicarbonate solution was used in all experiments, with the following composition: $CaCl_2$, 2.5 mM; KCl, 3.5 mM; NaCl, 117 mM; $MgSO_4$, 1.2 mM; KH_2PO_4, 1.2 mM; $NaHCO_3$, 56 mM; glucose, 11 mM.)

Maximum force of contraction of an isometric twitch for nerve and muscle stimulation was measured by a force transducer throughout the experiment. (Maximum force of contraction was found to be developed when the hemidiaphragm was 0.5 to 1.0 mm longer than resting length. Preparations were stimulated with a square wave pulse at a frequency of 12 c.p.m. and a duration of 0.2 ms.)

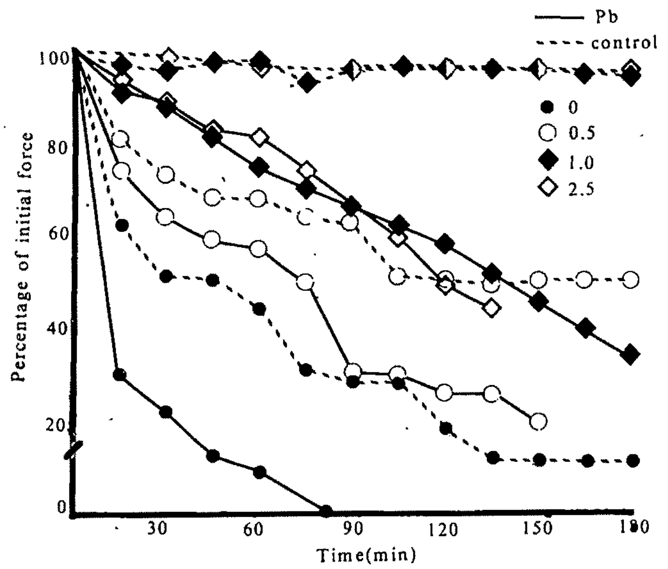

Fig. 1 Change in force of contraction (as percentage of initial force) over 3 h with varying concentrations of calcium, in lead-treated (8×10^{-5} M Pb) and control preparations. Points are means of three experiments.

All experiments were terminated after 4 h. Control preparations showed no significant decline in force of contraction nor significant changes in resting tension for the duration of the experiments.

Table 1 Effect of Lead on the Force of Contraction on Nerve and Muscle Stimulation after Treatment for 2 h

Concentration of lead ($\times10^{-5}$ M)	n	Percentage of initial force of contraction on stimulation through: Nerve	Muscle
0	15	97.5±2.5*	98.0±2.0
1	4	97.5±2.5	98.0±2.0
5	3	77.8±9.7	97.5±2.5
8	6	60.8±5.4	97.5±2.5
10	1	47.7	96.5

* Mean±s.e.m.

Preparations exposed to lead for 2 h showed significant decreases in the force of contraction when stimulated through the nerve (Table 1). The results are expressed as percentage of the initial force of contraction for nerve and muscle stimulation of each preparation. There was no decrease in the force of contraction in controls or in preparations treated with 1×10^{-5} M lead. At 5×10^{-5} M lead, however, the force of contraction on nerve stimulation was reduced significantly to 78% of the initial force (Student's t test[6]). When the same preparations were stimulated through the muscle, no significant decreases in force of contraction were seen at concentrations of lead up to 1×10^{-4} M.

In a separate series of experiments, calcium was added to for preparations after exposure for 2 h to 8×10^{-5} M lead. All preparations demonstrated a decrease in nerve-stimulated force of contraction to a mean of 58% of the initial force. Calcium, when added to produce a final concentration of 3×10^{-3} M, restored the force of contraction to a mean of 91% of initial force for 28 min.

A second series of experiments was done to determine the effect of the concentration of calcium in the bathing medium on the time required for lead to affect nerve-stimulated force of contraction. The concentration of calcium was varied from 0 to 2.5 mM (isotonicity was kept constant by appropriate adjustments in the concentration of NaCl). Isometric twitch tension was measured over 3 h for controls and preparations treated with 8×10^{-5} M lead. Increasing the concentration of calcium from 0 to 1 mM significantly increases the time for equivalent impairment of nerve-stimulated force of lead-treated preparations (Fig. 1). That is, for a given time of exposure to lead, the extent of impairment was inversely related to the calcium concentration. At calcium concentrations above 1 mM, however, no further protection against lead treatment was found.

The motor endplate was tested for possible site of lead action by the addition of exogenous acetylcholine in a range of concentrations from 1×10^{-7} to 5×10^{-6} M to the preparations after treatment for 2 h with 8×10^{-5} M lead. The contraction produced by equimolar additions of acetylcholine was identical in control and lead-treated preparations. These results tend to eliminate the motor endplate as a possible site of the primary toxic actions of lead.

The calcium experiments demonstrated that additions of calcium to normal Krebs–Ringer solution reversed the effects of treatment for 2 h with lead. Additional experiments demonstrated that the time course of impairment of neuromuscular function by lead was related to the concentration of calcium in the bathing media of the preparations. An apparent discrepancy arises between the protective and the reversing effects of calcium. Increasing the concentration of calcium from 1 to 2.5 mM did not significantly change the time course of impairment by lead. In lead-poisoned preparations, however, the addition of 0.5 mM calcium after treatment for 2 h caused a significant recovery of neuromuscular function for 28 min. The timing of calcium addition may be important in producing this reversal. These experiments indicate that calcium and lead may interact in some manner at a site important in neuromuscular function.

The experiments demonstrated that lead, in concentrations greater than 1×10^{-5} M, significantly decreased the force of contraction of the rat hemidiaphragm muscle on phrenic nerve stimulation. Over the same range of concentrations, force of contraction was not affected when the muscle was stimulated directly. Since muscle was not directly involved in the lead toxicity seen in these experiments, the effects of calcium are probably confined to junctional sites. This suggests that lead interferes with either the release of acetylcholine or the uptake of choline and subsequent synthesis of acetylcholine, processes known to have a requirement for calcium (ref. 7 and C. Pert and S. H. Snyder, personal communication).

Absence of Significant Chromosome Damage in Males Occupationally Exposed to Lead

THE hazard to man of environmental contamination by certain metals is of considerable importance and in this context the organic and inorganic compounds of lead are the subject of much current interest. The clinical effects on the individual of accidental overexposure to lead are well known. What is perhaps not so widely realised, however, is that there is the possibility that high lead levels may be hazardous to the foetus of exposed parents. "Intoxication with lead" is often quoted as "reducing fertility and increasing the frequency of abortions and miscarriages" in man[1–5], and some animal studies have shown[6] that administration of lead salts may result in an increase in congenitally malformed offspring. These findings, the reported carcinogenicity of lead salts in rats[7], and the earlier reports that salts of a variety of heavy metals induce aberrations in plant chromosomes[8,9], have stimulated a number of *in vitro* and *in vivo* studies into the possible mutagenic effects of lead which have yielded conflicting results.

Schwanitz *et al.*[10] reported a three- to four-fold increase in chromosome aberration frequency in human lymphocytes treated *in vitro* with lead acetate as compared with control cells exposed to sodium acetate. In contrast, an extensive *in vitro* study on cultured Chinese hamster fibroblasts by Bauchinger and Schmid[11] showed no difference between control (sodium acetate) and lead acetate treated cells.

In vivo studies on mice fed on a diet containing lead acetate were reported to reveal an increased incidence of chromatid damage in cultured bone marrow cells from treated as compared with control animals. But other investigations[12] on the effect of tetraethyl lead and lead acetate in the mouse showed that neither compound, even at the maximum tolerated dose levels, promoted a dominant lethal response. In man, an increase in chromosome aberrations, particularly chromatid breaks and gaps, was reported by Schwanitz *et al.*[10] to occur in the peripheral blood lymphocytes of eight male workers in a lead oxide factory.

In view of these conflicting reports our study was set up to examine the extent of chromosome damage, and any correlations between the level of damage and the lead levels in blood and urine, in a population of men occupationally exposed to oxides of lead.

The population, described in greater detail in the accompanying paper[13], consisted of seventy male workers employed by a shipbreaking yard. Thirty-five men (Group 1) were engaged as burners to cut the hulls and all metal structures of ships, and their lengths of exposure ranged from 3 months to 43 yr. Their age range was 21–63 yr and the average weekly exposure time was 50 h. The remaining thirty-five men were of comparable age, were not actively engaged in burning, and formed a control group (Group 2).

All the men were medically examined and a full medical and occupational history taken[13]. Each worker had a periodic mass chest X ray and many had also received further radiation exposure for investigations of bone fractures and stomach ulcers. None of the men had undergone radiotherapy, and none were receiving drugs considered to produce chromosome damage. Blood samples from the men were analysed for lead content and routine haematology, and urine samples for lead and coproporphyrins[13].

The sample of blood obtained from each individual for chromosome analysis was coded by a person not concerned in the study, before being set up in culture. The lymphocytes were cultured in Hams F10 medium with 14% bovine serum and colcemid added for the last 3 h of culture. For slide preparation, the cells were subjected to a brief hypotonic treatment with KCl[14] before fixation in 3:1 (methanol-acetic acid) and preparations were made by air drying. To minimise any culture artefacts and to ensure that the majority of the dividing lymphocytes were examined at their first *in vitro* metaphase, the total culture time was either 45 or 48 h. One hundred mitoses with forty-five centromeres or more from each individual were studied by one person. The first two cells were fully analysed to ascertain the chromosome constitution of the individual and all cells were scored for aneuploidy and chromatid and chromosome aberrations.

The blood of sixty-six of the seventy workers was cultured successfully but the cultures from the four remaining individuals, all of whom were in Group 2, yielded few mitoses of good quality and were not scored for aberrations. One of these men was found to have a 47,XYY chromosome constitution, but the remainder had normal male karyotypes.

After the scoring was completed, the slides were decoded and the cytological results obtained from the burners (Group 1) compared with those from the intended controls (Group 2). At the same time, the results from the toxicological studies were made available and from these it was apparent that a large proportion of men in the intended control group had elevated lead levels in blood and urine at the time of sampling due, presumably, to their working in the vicinity of the burners. The cytogenetic results summarised in Table 1 have therefore been divided into the four classes, A to D, based on lead levels in blood[13], and further subdivided into results obtained on individuals in Groups 1 and 2 within each class.

Analysis of the data presented in the form shown in Table 1 did not reveal any consistent and significant differences between the incidence of chromosome-type and chromatid-type aberrations between Groups 1 and 2 or between classes A, B, C and D. Moreover, the results within any class were similar to those obtained from previous surveys of adult males from a variety of groups that were not considered to be unduly exposed to known or suspected mutagens (Table 1).

In considering the comparisons made between groups having different blood lead concentrations, it should be remembered that both blood and urine samples for lead estimations were obtained at the same time as blood for culture, so that these lead estimates relate only to the levels in those individuals on that particular day. The lead level in blood depends on the degree of exposure over the few days before sampling and may therefore vary considerably. On the other hand, chromosome damage in human peripheral leukocytes can reflect damage sustained many years before blood sampling (for example, in individuals exposed to ionising radiations, see below). For this reason, although we had not found any significant differences between the different blood lead-level classes, or between Groups 1 and 2, further comparisons were made within the Group 1 population. Attention was paid to the duration of exposure (number of years worked in the yard and any previous occupational history) and also to the presence of any physical or clinical (including haematological) symptoms which, however mild, could be indicative of lead poisoning. These analyses did not reveal any bias of the distribution of aberrations within the subgroups.

Although the data from the workers exposed to lead fume showed very small increases in the frequencies of chromatid breaks, and in the total number of cells with chromosome-type aberrations, the aberration frequencies were very low and were not significantly different from either control population, despite the fact that the burners, as a group, had possibly received more diagnostic X-ray exposure. There was, however, a significant difference (χ^2 (1 degree of freedom) = 31.4, $P < 0.01$) between burners and controls from the general population (but not shipyard controls) in the total number of cells which had chromatid-type aberrations. This was due to an increased incidence of chromatid and isochromatid gaps and chromatid breaks in the Group 1 men (Table 1). The scoring of these particular aberrations is extremely subjective, and whereas the cells from the Group 1 individuals were scored by a single observer, the figure derived from the 'general population' is a combination of results from several observers. These parameters of chromosome damage may be unreliable indicators due to the difficulties of distinguishing achromatic non-stained regions (gaps) and of confusing them with chromatid and isochromatid discontinuities (breaks). These can only be reliably distinguished by observing the cells at metaphase and anaphase and thus following the types of metaphase aberrations which produce fragments at anaphase. We must therefore conclude that our results do not point to an increased chromosome aberration frequency in the peripheral blood lymphocytes of individuals chronically exposed to high levels of lead oxides.

While our study was in progress, Bauchinger and Schmid[15] reported on results obtained on lymphocyte chromosomes of twenty industrial workers who had been exposed for several years to lead dust, and on twenty-nine policemen "employed in the Munich areas with the highest traffic density" and who showed a 20–30% increase in blood lead levels as compared with the average population. In this work cells were cultured for 46 h and in neither of these groups was there any increase in aberration yield levels over controls.

In recording our negative findings, it is important to ask what value can be placed on the earlier reported positive result of Schwanitz *et al.*[10]. In that study no information is given on the duration of culture and on whether blood cultures from control and exposed individuals were set up in the same way and at the same time. The authors recorded approximately twice as many mitoses in cultures from exposed as from control individuals and if, as seems probable, the cells from the exposed individuals were cultured for 3 d, then a large proportion of the metaphase cells may have been in their second or later mitosis in culture[16,17]. It is well known, from studies on normal and irradiated human blood cells, that the incidence of gaps and chromatid aberrations in lymphocyte chromosomes is increased if cells are allowed to proceed through two or more cycles in culture, as also is the incidence of polyploid mitotic figures and of "derived" chromosome-type changes[18]. The fact that Schwanitz *et al.*[10] observed some eighteen tetraploid metaphases in a total of 800 scored in the exposed individuals (compare the 0 in 3,500 scored in the present work) and that the excess aberrations in this group were "secondary aberrations", that is, largely chromatid and isochromatid gaps, suggests that most of these aberrations were not present in these cells *in vivo*, but developed during culture. This suggestion raises the very important general question of interpretation in the case of chromosome damage in lymphocytes obtained from individuals who may or may not have been exposed to an environmental mutagen.

Many of the lymphocytes in human peripheral blood are long lived and a significant proportion rarely undergo mitosis *in vivo*[19]. Chromosome damage sustained by these cells at the time of their exposure to a mutagen may therefore be detectable for many years after exposure, as in the case of the Japanese A-bomb survivors who show high aberration yields some 25 yr after their original exposure[20]. Circulating lymphocytes are in a G_1 state so that exposure to ionising radiations induces chromosome-type changes where the unit of breakage and exchange is the whole chromosome giving the characteristic dicentrics, rings and chromosome fragments. Irradiation of the S or G_2 phases of the cell cycle gives chromatid-type aberrations where the unit of breakage or exchange is the single chromatid. In contrast with ionising radiations, many chemicals produce only chromatid-type aberrations in the first and subsequent mitosis following exposure, even though the cells may have been exposed to the mutagen while in the G_1 phase of the cycle[18]. The less frequent chromosome-type changes seen in second, or later, divisions following treatment with these chemical mutagens result from the duplication of chromatid aberrations that were transmitted to daughter cells, and are thus 'derived' chromosome changes[18].

In the case of chronic *in vivo* exposure to a chemical mutagen, one might expect to observe both chromatid and derived chromosome damage in lymphocytes at their first mitosis in culture. The incidence of such damage will, however, be dependent not only on the accumulated dose, but also on the interval between exposure and time of sampling for culture. With increasing time there would be an increasing probability of obtaining derived chromosome changes due to cell turnover *in vivo*, but a corresponding reduction in the incidence of chromatid-type changes due to cell, and aberration, loss and possibly also to repair of lesions in G_1 chromosomes. Chromatid damage observed at the first mitosis in culture will therefore be heavily influenced by the amount of mutagen present in the body over a relatively short time before sampling and also by the amount of mutagen inevitably carried over in the blood into the culture medium.

Table 1 Cytogenetic Findings in Cultured Lymphocytes from Shipyard Workers with an Occupational History of Lead Exposure (Group 1), and from Shipyard Controls (Group 2) and Other Adult Males

					Cells with chromatid aberrations					Cells with chromosome aberrations

* Number of structurally abnormal monocentric chromosomes observed which were not associated with an acentric fragment.

† Data obtained from previous MRC surveys of other adult male groups with no history of undue exposure to known or suspected mutagens (lymphocyte culture time <50 h).

‡ Includes non-modal cells.

In terms of potential genetic hazard to a population, the production of a low level of damage in a large number of individuals is of greater consequence to the population than the induction of large amounts of damage in a small number of individuals. The human peripheral blood lymphocyte offers a convenient means of detecting low levels of chromosome damage which might be caused by an environmental agent and may provide a useful screening system. But, apart from the considerable technical labour involved, there may be difficulties both with the interpretation of chromosome aberration data and with the extrapolation of results from somatic to germ cells. Problems of interpretation are further complicated by mutagens which produce chromatid-type aberrations, since similar changes may also develop in cultured cells as a consequence of infection or of non-specific 'adverse culture conditions'. In such work it is obviously of paramount importance to use optimum culture conditions and to obtain proper control specimens matched not only in terms of donor characteristics but also with regard to culture conditions.

Lead Over-absorption in a Population of Oxy-gas Burners

Pliny (AD 23-79) observed that in the second century BC the ancients painted their ships with native ceruse (white lead), that lead poisoning was known in his day and that the workers in lead products tied up their faces in loose bags lest they should inhale the pernicious dust[1]. In a survey of 228 men in nine shipbreaking yards in Scotland and NE England, McCallum[2] focused attention on the health hazard resulting from burning lead-painted metal with a high temperature flame. He found 36% of the burners with a haemoglobin content less than 12.5 g per 100 ml of whole blood. In this operation, in which oxy-gas torches have been used at the work face, temperatures are in the region of 3,000–3,500° C. Iron melts at 1,535° C and is found in vapour form at 3,000° C. Lead melts at 328° C and boils at 1,740° C. This produces a risk of excessive exposure in compartments and between decks of ships, of which lead from paintwork is the principal risk[3]. In the breathing zone of the burner, with maximum concentrations of fume at torch level, may also be found zinc (zinc metal fume fever), copper from piping and cadmium from protective coatings[4].

The limitation of statutory control measures and the difficulty of clinically detecting lead absorption (as opposed to lead poisoning) have led to ineffective control in shipbreaking processes compared with other industries with a known lead risk (as, for example, in lead accumulator manufacture). The evaluation of the degree of lead absorption and the identification of lead overexposure is clearly the right objective in modern conditions, rather than the identification of lead poisoning[5]. It is not yet known what levels of lead absorption are tolerable but Lane *et al.*[6] have proposed four arbitrary categories, (A) absorption found in the 'normal' population (blood lead <40 μg per 100 ml; urinary lead <80 μg l^{-1}); (B) increased but acceptable absorption (blood lead 40–80 μg per 100 ml; urinary lead 80–150 μg l^{-1}); (C) excessive and unacceptable absorption (blood lead 80–120 μg per 100 ml; urinary lead 150–250 μg l^{-1}); and (D) dangerous absorption, suspend automatically from work with lead (blood lead >120 μg per 100 ml; urinary lead >250 μg l^{-1}).

This paper is concerned with the examination of a population of oxy-gas burners in a shipbreaking yard exposed to lead fume in their work environment. In the accompanying paper[7] cytogenetic studies on this population are described.

In one shipbreaking yard thirty-five males engaged on oxy-gas burning (Group 1) and a control group of thirty-five men of comparable age employed as labourers, crane drivers, and so on (Group 2) were investigated. The age distribution of the population and the length of time the oxy-gas burners had been actively burning are shown in Tables 1 and 2.

Table 1 Ages of Burners and Controls in Ten-yr Age Groups

Age (yr)	No. of burners, ship and shore (Group 1)	No. of controls (Group 2)
15–24	6	6
25–34	11	3
35–44	2	9
45–54	8	9
55–64	8	8
Total	35 (Mean age 41 yr)	35 (Mean age 43 yr)

Table 2 Length of Time Employees (Group 1) had been Burners

Oxy-gas burning (yr)	Number of Men	%
Up to 5 yr	20	57
5 yr and over	15*	43
Mean 8.8	35	100

* Two of these men had 42 and 43 yr continuous burning.

A full occupational and medical history, including previous spells of burning at other yards, was obtained for burners and controls, with emphasis on the symptoms of lead absorption, which are colic, dyspepsia, lassitude and loss of appetite, constipation, muscle aches and headache. The physical signs of lead over-absorption, such as paresis, pallor and blue line on the gums, were then looked for. In the first survey a sample (20 ml) of venous blood was taken from each man and divided into two equal parts, one being used for lymphocyte culture for chromosome analysis and the other for blood lead content and haematological studies. In addition, urinary lead determinations were carried out by the Central Reference Laboratory of the Department of Employment. In order to obtain a more accurate picture of the extent of lead absorption of this population previous to and at the time of the cytogenetic study, four additional burner population surveys for blood and urine lead were made at three-monthly intervals. An environmental survey was carried out by the Industrial Hygiene Laboratory of HM Factory Inspectorate. Samples were taken from the breathing zone of burners cutting heavily painted panels of a merchant ship and of a naval frigate.

The mean figures obtained for the burners and controls from the first survey for lead levels in blood and urine are shown in Table 3, together with the positive findings of the clinical examination. It should be noted that the thirty-five burners sampled gave a mean haemoglobin value of 14.8 g per 100 ml with seven under 14.0 g and one under 12.5 g per 100 ml.

Table 3 Survey 1. Lead Levels of Blood and Urine, and Clinical Symptoms

Population	Blood lead (μg per 100 ml)	Urine lead (μg l^{-1})	Colic	Constipation	Pallor	Lassitude	Blue line
Group 1*	mean=91.0 (35 men)	median=144 (32 men)	4	3	4	4	5
Group 2†	mean=49.7 (34 men)	median=24 (32 men)	–	–	–	–	–

* Oxy-gas burners.
† Controls.

The difference in mean blood lead levels between Group 1 and the Group 2 controls is significant at the 0.1% level. A number of urine lead estimations were below the lower limit of detection of the chemical method, so that the urine lead results were analysed by non-parametric tests where medians were used instead of means. The difference between the oxy-gas burners and the control population was once again significant at the 0.1% level. The detailed data, together with the results from subsequent surveys on the burner population, are summarised according to the classification of Lane *et al.*[6] in Tables 4 and 5.

Table 4 Lead Absorption Categories[6] in Blood in the Four Surveys of a Population of Oxy-gas Burners

Survey	Date	Absorption category (μg per 100 ml) A Normal (<40)	B Acceptable (40–80)	C Excessive (80–120)	D Dangerous (>120)	Total No. of burners
1	November 1971	14	19	2	0	35 controls
1	November 1971	0	16	15	4	35
2	April 1972	0	9	17	12	38
3	July 1972	3	24	7	0	34
4	November 1972	12	24	2	0	38

The results of the environmental survey showed that from heavily painted plates of a merchant ship and hull sections of a warship, concentrations approaching 4.0 mg and 14.0 mg m^{-3} lead-in-air respectively were produced in the breathing zones. These values are very much higher than the threshold limit value for a 40 h week of 0.2 mg m^{-3} (ref. 8). There is, however, no accurate method of computing actual lead intake from concentrations of lead-in-air which vary over very wide limits dependent on the presence or absence of lead paint, constantly varying air movements, and variable absorption due to voluntary use of respirators.

Table 5 Lead Absorption Categories[6] in Urine in the Four Surveys of a Population of Oxy-gas Burners

Survey	Date	Absorption category (μg l^{-1}) A Normal (<80)	B Acceptable (80–150)	C Excessive (150–250)	D Dangerous (>250)	Total No. of burners
1	November 1971	28	5	0	0	33* controls
1	November 1971	6	11	10	7	34*
2	April 1972	10	16	6	6	38
3	July 1972	15	15	4	0	34
4	November 1972	23	12	3	0	38

* Excluding samples that were contaminated and not recorded.

The results of biological tests on the thirty-five oxy-gas burners in this study confirm the views of McCallum[2,3]. In our initial survey, high blood lead levels were found in some of the selected controls, but all individuals in Group 1 had more than 40 μg of lead per 100 ml of blood, with four men in the dangerous (D) category (Table 4). In the second survey carried out three months later, a greater proportion of the exposed population had higher blood lead levels, with twelve men in the D category. These burners with the highest blood lead levels were then removed from burning where there was any risk of lead in the fume and subsequent surveys (Table 4) showed a marked reduction in blood lead levels. The urine lead values (Table 5), while not correlating with the blood values, showed the same degree of improvement over one year's monitoring. The data obtained in these surveys show that by close supervision of the work situation, it is possible to achieve a degree of lead absorption which is acceptable by today's arbitrary standards.

A number of questions remain unanswered in the present shipbreaking work environment. One is the permanence or long-term medical effects of lead absorption in which Rieke[9] has recently expressed concern, particularly with regard to the detection of so-called 'susceptible' burners. A second is the possibility of chromosome damage and this is the subject of the accompanying paper[7].

Clonal Restriction of the Immune Response to Phosphorylcholine

THE antibody response to most antigens is chemically heterogeneous, reflecting clonal heterogeneity of the responding cells. This heterogeneity may arise in part from the number of different epitopes present in the structure of complex antigens, although the antibody response even to chemically simple haptens (which may contain more than one epitope) is often very heterogeneous. For example, the dinitrophenyl hapten on a protein carrier elicits many different anti-hapten antibodies which are distinguished by isoelectric focusing[1]. Also, individual mice respond to the *p*-azobenzoate and to the *p*-azophenylarsonate haptens by producing a population of serum antibodies with many idiotypic specificities[2]. Certain carbohydrate antigens, however, seem to induce relatively homogeneous antibody responses[3,4]. One of these antigens, the C-polysaccharide from the rough strain of pneumococcus R36A, induces a restricted antibody response directed against phosphorylcholine[5], a structural component of the C-polysaccharide[6].

We have examined the antibody response of Balb/c mice to phosphorylcholine by testing various inhibitors for their capacity to interfere specifically with antibody activity. These inhibitors include (*a*) phosphorylcholine and phosphorylcholine analogues to determine the epitopic specificity of the antibodies and (*b*) antisera raised against myeloma proteins which have antibody activity against phosphorylcholine. These anti-idiotypic sera provide a measure of the idiotypic, and thus clonal homogeneity of the response. By these methods we find that the antibody response is remarkably homogeneous and has the characteristics of a so-called "monoclonal" response. In fact, the antibody response is equally homogeneous whether immunisation is with the C-polysaccharide or with phosphorylcholine coupled to various protein carriers. Furthermore, when this response is suppressed, other clones of cells producing antibody to phosphorylcholine do not appear.

p-Diazophenylphosphorylcholine was synthesised according to the method of Chesebro and Metzger[7]. This compound, in *p*H 9.2 borate buffer, reacts with tyrosyl residues of proteins to yield the conjugated hapten, *p*-azophenylphosphorylcholine (PC). Balb/c mice were immunised with PC conjugated to keyhole limpet haemocyanin (PC-KLH) or PC conjugated to *Salmonella* flagella (PC-FLA). The synthesis of antibodies by individual spleen cells was demonstrated by the haemolytic plaque technique, using as target cells sheep erythrocytes conjugated with PC (PC-SRBC)[5].

Table 1 Response to *p*-Azophenylphosphorylcholine Conjugated to Different Carriers

Antigen	Carrier priming	PFC per spleen $\times 10^3$
10^9 cells R36A	—	78.4± 6.3
200 μg FLA	—	2.3± 1.2
200 μg PC-FLA	—	287.3±27.0
20 μg PC-FLA	—	162.0± 7.2
200 μg KLH	—	0.9± 0.2
200 μg PC-KLH	—	151.0±18.0
20 μg PC-KLH	—	95.0±13.0
200 μg PC-FLA	5 μg FLA	269.0±20.8
20 μg PC-FLA	5 μg FLA	148.3±16.0
200 μg KLH	5 μg KLH	1.8± 0.6
200 μg PC-KLH	5 μg KLH	439.8±52.4
20 μg PC-KLH	5 μg KLH	328.4±24.3

8–12-week-old Balb/c mice were immunised intravenously with antigen 4 d before being assayed for their splenic PFC response. PC-KLH and PC-FLA were in saline solution while the R36A vaccine was a saline suspension of the formalin-killed bacteria[5].

The magnitude of the IgM plaque-forming cell response is given in Table 1; about 8×10^4 plaque-forming cells (PFC) per spleen were detected in mice immunised with the R36A pneumococcal vaccine while immunisation with either 200 μg of PC-KLH or of PC-FLA induced about 15×10^4 and 30×10^4 PFC per spleen respectively. Immunisation with either carrier alone caused an insignificant response to PC. Thus, the hapten on either carrier elicited a splenic PFC response slightly greater than that induced by the vaccine. When mice were primed with a small dose of KLH 3 d before immunisation with PC-KLH, the anti-hapten response was about three times greater than the response obtained from unprimed mice. No such carrier priming effect was observed with the PC-FLA antigen.

While the effect of carrier priming was demonstrable for PC-KLH, the effect of priming is even more pronounced for other carriers. For example, PC coupled to bovine gamma globulin (BGG) induces a very low response in Balb/c mice; however, the response is comparable with that reported here when mice are primed with BGG (W. L., unpublished results). Thus, carrier-specific cells are required, at least for some PC-carrier conjugates; and, by inference, the magnitude of responses to these conjugates is a function of the number of carrier-specific cells present.

Indirect plaques were not detected during the primary or the secondary response to PC induced by immunisation with either PC-KLH or PC-FLA. The developing serum used for enhancement of IgG PFC was a goat anti-mouse IgG serum which was effective for demonstrating indirect plaques against sheep red blood cells (SRBC)[8]. Apparently, the response is restricted to production of IgM antibodies.

The specificity of the PFC response to PC was studied using analogues of *p*-azophenylphosphorylcholine to inhibit plaque formation by spleen cells from mice immunised with different PC-carrier conjugates; 10^{-2} mg ml^{-1} PC-BSA or 10^{-2} M phosphorylcholine solutions inhibited formation of plaques. In contrast, choline alone, acetylcholine alone or 2-dimethylaminoethylphosphate alone, at the same molarity, failed to inhibit plaque formation, Table 2*a*. Thus, it seems that the intact zwitterionic phosphorylcholine molecule is required to inhibit the binding of anti-hapten antibodies to the PC-SRBC. None of the above compounds inhibited plaque formation by spleen cells from mice immunised with

Table 2 Inhibition of Plaque Formation

Inhibitors	% Inhibition of anti-hapten plaques from mice immunised with			
	PC-FLA	PC-KLH	PC-KLH (KLH-primed)	TNP-KLH
(*a*) Hapten analogues				
—	0±3%	0±4%	0±2%	0±4%
10^{-2} M phosphorylcholine	98±2%	98±3%	99±2%	4±3%
10^{-2} mg ml^{-1} PC-BSA	97±2%	97±2%	97±3%	2±4%
10^{-2} M choline	0±2%	2±4%	4±3%	0±4%
10^{-2} M acetylcholine	1±4%	1±4%	4±2%	0±4%
10^{-2} M 2-dimethylaminoethyl phosphate	1±4%	3±3%	2±3%	2±7%
10^{-2} mg ml^{-1} BSA	−6+5%	−2±4%	0±4%	2±5%
(*b*) Anti-idiotypic sera				
anti-TEPC-15	97±3%	99±3%	96±2%	−2±4%
anti-MOPC-167	−2±3%	−7±5%	0±4%	−5±4%
anti-McPC-603	5±3%	4±4%	7±4%	2±4%

The anti-hapten PFC were from Balb/c mice immunised intravenously with antigen 4 d before assay. Inhibition of plaque formation was carried out as described previously[5]. The effect of each inhibitor was assayed in triplicate. Inhibition is presented as the % inhibition of plaques±s.e. by each agent. Anti-TNP plaques were used to test for the non-specific inhibitory activity of the agents used. Anti-TNP PFC were assayed using TNP-SRBC as target cells[9]. The anti-idiotypic sera used for plaque inhibition were absorbed with normal Balb/c serum, heat-inactivated and diluted 1 : 100 in Hanks balanced saline solution before use in this assay. The concentration of phosphorylcholine required for 50% inhibition is the same for PFC from PC-FLA, PC-KLH or R36A immunisation. Furthermore, the inhibition curve for plaques from animals immunised with PC-KLH indicates homogeneity of binding affinities among the PFC (W. L., unpublished results).

the trinitrophenyl hapten conjugated to KLH (TNP-KLH) and assayed against TNP-SRBC[9]. From these findings, we conclude that the anti-PC response measured by this assay is directed to phosphorylcholine itself and not to determinants introduced by the conjugation of phosphorylcholine to carriers.

The idiotypic homogeneity of the response to the PC hapten was studied by the plaque inhibition technique[5] using antisera raised against the myeloma proteins TEPC-15, MOPC-167 and McPC-603. Although these Balb/c myeloma proteins bind phosphorylcholine, each possesses a different idiotype[10]. The antisera, raised in A/He mice[5,10] to these three proteins, were used to determine the idiotypic specificity of the PFC response to PC, Table 2*b*. Anti-MOPC-167 and anti-McPC-603 had no inhibitory effect while anti-TEPC-15 inhibited plaque formation by cells from mice immunised with either of the PC-carrier conjugates. None of the antisera inhibited plaque formation to the TNP hapten. Thus, the response to phosphorylcholine is of an idiotype identical to or cross reactive with the idiotype of the TEPC-15 myeloma protein.

Mice given anti-TEPC-15 serum before immunisation have reduced responses to phosphorylcholine[11]. Suppression is due to inhibition of immunisation rather than to inhibition of plaque formation, since no suppression occurs when the antiserum is given 1 d after immunisation[11]. In our experiments, anti-TEPC-15 sera were administered to Balb/c mice 1 d before immunisation with PC-carrier, Table 3. The response of these mice, after immunisation with PC-FLA or PC-KLH, was less than 5% of the response of normal mice immunised with the same antigen. The idiotypic specificity of suppression was demonstrated by the failure of anti-MOPC-167 or of anti-McPC-603 to suppress the responses induced by PC-KLH. That the suppression was specific for the PC hapten was shown by the inability of anti-TEPC-15 serum to diminish the response to the TNP hapten. In fact, when mice were immunised with both PC and TNP conjugated to the same carrier molecule (PC-KLH-TNP), anti-TEPC-15 serum suppressed only the response to PC, Table 3; obviously carrier-specific helper cell activity for TNP is not affected by suppression of the response to PC.

Table 3 Specific Suppression of the Response to Phosphorylcholine by Anti-idiotypic Serum

Antigen	Antiserum	PFC per spleen × 10^3 PC	TNP
50 µg PC-FLA	—	112.9 ± 12.1	
50 µg PC-FLA	anti-TEPC-15	1.6 ± 0.9	
200 µg PC-KLH	—	140.5 ± 11.7	
200 µg PC-KLH	anti-TEPC-15	3.1 ± 1.3	
200 µg PC-KLH	anti-MOPC-167	136.3 ± 8.2	
200 µg PC-KLH	anti-McPC-603	154.2 ± 13.5	
200 µg TNP-KLH	—		283.9 ± 15.4
200 µg TNP-KLH	anti-TEPC-15		294.0 ± 23.9
200 µg PC-KLH-TNP	—	99.6 ± 12.9	120.3 ± 4.0
200 µg PC-KLH-TNP	anti-TEPC-15	1.9 ± 1.3	106.8 ± 10.3

Balb/c mice treated with anti-idiotypic sera were given 0.3 ml of the appropriate antisera intravenously 1 d before immunisation with antigen, and their spleens assayed for anti-hapten PFC 4 d after immunisation. Anti-PC PFC were assayed using PC-SRBC as described in Table 1. Anti-TNP PFC were assayed using TNP-SRBC[9]. The anti-hapten PFC per spleen are the mean from groups of three mice ± s.e.m.

Whereas suppression of induction of the response to PC by antibody to TEPC-15 is considerable, it is not complete. The PFC still detectable in suppressed mice were analysed to determine whether the antibodies secreted by these cells were directed to phosphorylcholine and if so whether they bear the TEPC-15 idiotype. The results, Table 4, indicate that about 50% of these residual plaques are no longer inhibited by free phosphorylcholine. Of the plaques that are inhibitable by phosphorylcholine, apparently very few, if any, are of the TEPC-15, MOPC-167 or McPC-603 idiotypes, since the antisera to these myeloma proteins did not significantly inhibit the residual plaques. Thus, the epitopic specificity and the idiotypic composition of the residual response after suppression with anti-idiotypic serum to TEPC-15 are different from the normal anti-PC response.

We have shown that Balb/c mice respond as well to phosphorylcholine whether they are immunised with the R36A pneumococcal vaccine or with *p*-azophenylphosphorylcholine-carrier conjugates. The inhibition studies demonstrate that the measured response to *p*-azophenylphosphorylcholine is directed to the phosphorylcholine moiety of the hapten. The response to phosphorylcholine is also restricted to the idiotype present in the TEPC-15 myeloma protein regardless of the carrier used to induce the antibody response. Furthermore, priming with carrier does not affect this idiotypic restriction. These findings lead us to conclude that the same B cell clone or clones having receptors for phosphorylcholine are stimulated regardless of the carrier used. Apparently the carrier has no effect on the selection of the B cell clone responding to PC.

Table 4 Analysis of the PFC Remaining after Suppression by Anti-Idiotypic Serum

Inhibitor	% Inhibition of anti-PC plaques from mice immunised with PC-FLA	PC-KLH (KLH-primed)
—	0 ± 5%	0 ± 7%
10^{-2} M phosphorylcholine	54 ± 7%	45 ± 9%
10^{-2} mg ml^{-1} PC-BSA	96 ± 4%	95 ± 6%
anti-TEPC-15	7 ± 4%	6 ± 6%
anti-MOPC-167	−4 ± 7%	−4 ± 8%
anti-McPC-603	13 ± 6%	1 ± 10%

The plaques studied here were from animals suppressed with anti-TEPC-15 and immunised with 200 µg of PC-carrier intravenously 1 d later. PC-KLH-immunised mice had been primed with 5 µg KHL 3 d before immunisation. The assay technique and the statistical analysis were the same as those used for the data in Table 2.

The residual response in suppressed mice is not of the TEPC-15 idiotype. Furthermore, this response may involve the chemical bridge between PC and the carrier, since plaque formation is suppressed by PC-carrier but not by phosphorylcholine alone. Whether this residual response is present as a minute and hence undetectable fraction of the normal response, or whether it arises only after suppression of the dominant TEPC-15 idiotype, remains undetermined.

The possibility existed that, on immunisation of mice with PC, expression of the dominant TEPC-15 idiotype might be responsible for suppressing the expression of other idiotypes. For example, in the heterogeneous responses to haptens such as DNP and *p*-azophenylarsonate, the loss of expression of one idiotype or clone is followed by compensatory activation of other clones, some of which were previously silent[12,13]. When the clone or clones of cells expressing the TEPC-15 idiotype are suppressed, however, other clones fail to expand appreciably, if at all. This makes it unlikely that expression of the dominant TEPC-15 clone is actively suppressing the other clones. Furthermore, mice suppressed with anti-TEPC-15, and then challenged several times with PC-carrier until a PFC response to PC is again detected, still expressed only the TEPC-15 idiotype (unpublished results of W. L.). This recovery from suppression with expression of the suppressed idiotype strongly suggests that the response of Balb/c mice to PC is restricted to the TEPC-15 idiotype. Presumably, this restriction in the adult Balb/c mouse is due either to clonal selection during ontogeny or to the absence or genetic deficiency of other clones. The study of the response to phosphorylcholine in mice which have been idiotypically suppressed at different stages of ontogeny may indicate the origin of this clonal restriction. In addition, the natural occurrence of a response which is restricted to the expression of one dominant idiotype may provide an experimental system for the study of the senescence of a repeatedly stimulated clone in the same animal. These possibilities are under investigation.

We thank Dr Donald A. Rowley for support and advice, Dr Ferenc J. Kezdy for advice and help in the synthesis of *p*-diazophenylphosphorylcholine, and Miss Ingrid Nebl and Mrs Helga Hong for technical assistance. This work was supported by US Public Health Service grants.

Lacunae in Erythrocyte Monolayers induced by Adherent Leukocytes

POLYMORPHONUCLEAR leukocytes are capable of migration, aggregation, adherence, and phagocytosis as well as the intracellular destruction of bacteria[1]. The observations reported here suggest yet another facility, namely that of repulsion. These experiments indicate that surface adherent leukocytes, whether polymorphonuclear or other types, repel erythrocytes from the immediate zone about them, thus creating lacunae.

Buffy coat fractions were obtained from fresh heparinised human blood by centrifugation in plastic tubing[2]. These were mixed in a vortex shaker with an equal aliquot of red cells diluted ten-fold in 0.9% sodium chloride solution. Ten microlitres of this was added to a siliconised glass slide, covered with an 18 mm circular coverslip, and the edges sealed with paraffin oil. After incubation at 37.5° C for between 30 min and 4 h, the slides were viewed at varying intervals over several days, magnification of 150 to 450, with ordinary phase, interference phase and darkfield phase illumination.

The usual preparation was a uniform monolayer of erythrocytes with a variable number of distinct, round, clear lacunae. In some instances, twin lacunae were seen, and in particularly thin preparations the "lake" pattern could be distorted. These lacunae in the erythrocytes developed early, increased in number and size on standing overnight, and persisted for days. Many were near the edge of the preparation, but they were also seen scattered uniformly throughout. In thick preparations, the lacunae appeared only as light areas in the diffuse redness of multilayered erythrocytes.

Most of the lacunae were acellular except for a single central cell identifiable as a polymorphonuclear leukocyte (Fig. 1), or occasionally as a monocyte, basophil, or lymphocyte. Occasionally, a few platelets or one or two red cells could be seen intruding into the lacuna. A few lacunae were completely devoid of even a central cell. Under phase microscopy[3] many lymphocytes could be identified among the erythrocytes, without any circumcellular space or lacunar formation. Similarly, platelet clumps were seen among the erythrocytes but again without any surrounding clear spaces.

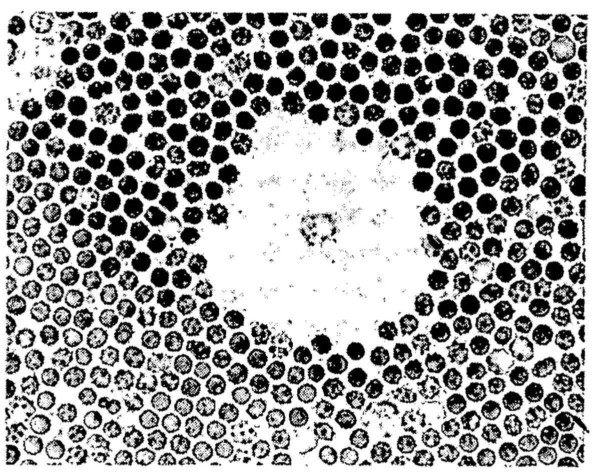

Fig. 1 View of lacuna which appears around an adherent polymorphonuclear leukocyte. In lower part of field, a lymphocyte floats freely in the erythrocytes, failing to show lacuna formation. Unstained, ×419.

The phenomenon of lacuna formation seems not to be limited to human blood, being similarly observed in rabbit, rat and mouse blood. It occurred on plain glass and plastic, as well as on siliconised glass slides, since the serum proteins present seemed to render the surfaces essentially the same[4]. Lacuna formation was also observed in blood contained in a capillary tube. It took longer for the lacunae to appear after incubation at room temperature than at 37.5° C. At 5° C lacuna formation was inhibited, in keeping with the known reduction in leukocyte adherence[5] at this temperature. Both heparinised and EDTA-treated blood were used and the red cells could be suspended successfully in a variety of diluents including Tyrode's and colloidal solutions. Using 1% phosphate buffered saline solutions it was found that acidic preparations were unsatisfactory but those at or above *p*H 7 were satisfactory. Use of borate buffers at *p*H 9 and 10 favoured early formation of lacunae. Red cell dilution was optimal between 1/6 and 1/32, the critical determinant being the achievement of a monocell layer of erythrocytes.

Individual differences in lacuna formation were noted, some of the most rapidly formed lacunae being found in patients with acute infectious disease. The use of vital stains to differentiate the cells did not interfere with lacuna production (Fig. 2*a*, *b*).

It was possible to induce streaming of the ambient red cells by applying gentle pressure on the coverslip. Although this resulted in an elliptical distortion of the lacuna it did not dislodge the central leukocyte, indicating that it is adherent. The significance of this adherence in the formation of lacunae was demonstrated in thick preparations, in which free floating non-adherent leukocytes could be seen unassociated with lacuna formation (Fig. 2*a*), at the same time that deeper focus on the same field (Fig. 2*b*) disclosed a single adherent leukocyte within each lacuna.

The mechanism of lacuna formation remains obscure. Although it can be argued that the weight of the coverslip[6] compresses the leukocyte to balloon dimensions, or that during adherence its hyaloplasm[7] extends to fill the entire lacuna, the cell body as seen with thiazine red R supravital staining, as well as with phase, is significantly smaller than the lacunar space. At first glance, these lacunae also resemble plaques of immune haemolysis[8] but the lacunae we observed are much smaller and phase microscopy reveals

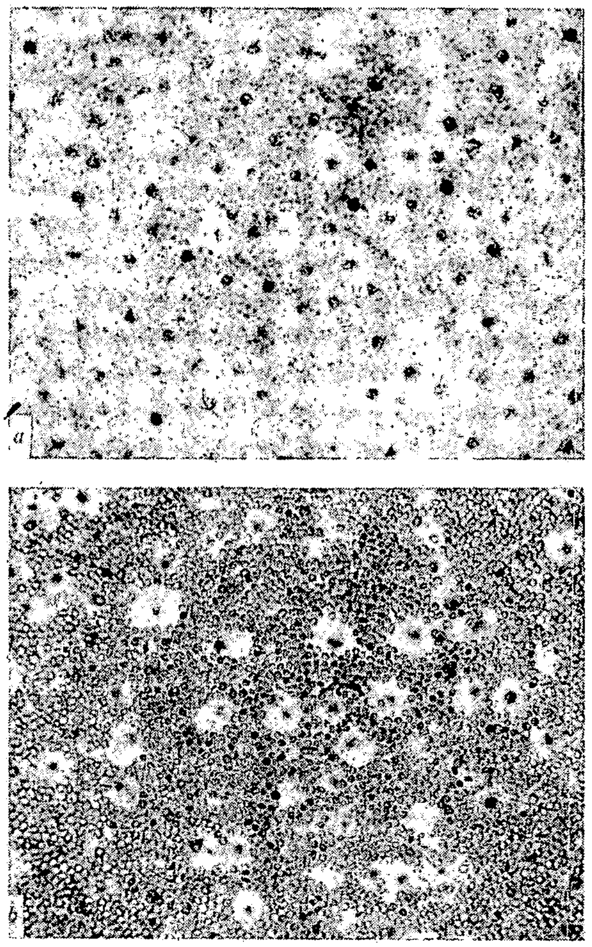

Fig. 2 Lacuna formation with leukocytes stained supravitally with iodonitrotetrazolium. Exactly the same field is seen at two levels. *a*, At higher level non-adherent floating leukocytes are seen with no relation to lacunar spaces. Lacunae are not in focus. ×174. *b*, At deeper level lacunae with central adherent leukocytes can be seen.

no haemolytic ghost cells within them[9]. Further, no foreign mixture of cells was used. Electrostatic forces could be deemed responsible for the erythrocyte repulsion, but changing the charge on the red cell by the addition of formalin or salmine sulphate (10^{-4}) to the diluent had no effect.

It seems more likely to me that the adherent leukocyte secretes a substance which produces a territorial space about it. In support of this is the fact that lacuna formation is accentuated by suspending erythrocytes in a borate buffer at *p*H 10 which could be expected to produce cell irritation. Rosenberg[10] has demonstrated by ellipsometry that the leukocyte can secrete a micro-exudate when in contact with glass, and this material can spread out to several cell diameters. Taylor later visualised such a cell exudate by immunological means[11] and observed that, by virtue of such liberated products, human conjunctival cells inhibit the spreading and contact relations of themselves and nearby cells[12].

In the monocellular layering technique described here, precisely such a leukocyte exudate may be responsible for the lacunae, the absence of erthrocytes indicating a secretion which inhibits their regular distribution and movement. I have been uniformly unsuccessful in staining or visualising any such material in the lacuna. Nonetheless, fixed slides, subsequently washed, show no cells but show clear lacunae by negative contrast when Giemsa stain is used and the slide viewed under phase. Further supporting the view that a secretion could be responsible is the fact that slides with lacunae, washed and resurfaced with red cells, show reformation of lacunae. Finally, it should be pointed out that lacuna formation was not dependent on the presence of erythrocytes, but rather on the adherent leukocyte. Thus, lacunae could be seen when either carbon particles (India ink 1/12), polystyrene latex particles (1.011 μm diameter, 10%, Dow), or colloidal silica (Ludox S 1/30, Dupont) was used in place of erythrocytes as a field indicator.

Further study of lacuna formation seems warranted since these lacunae may provide another source of information of the behaviour of the leukocyte in disease states and in the immune response.

Is the Area Postrema a Control Centre of Blood Pressure?

SEVERAL antihypertensive drugs have a central site of action[1]. The anatomical structures involved are unknown but there is evidence that some areas in the vicinity of the fourth brain ventricle mediate their effects[1]. Also in the region of the fourth ventricle noradrenaline[2–6] and γ-aminobutyric acid[7] bring about a depression of the cardiovascular system.

Recently it has been reported that the area postrema, which lies outside the blood-brain barrier[8] and protrudes into the fourth ventricle, mediates the central cardiovascular response to angiotensin II in the dog[9]. The area postrema bears a close histological resemblance to the carotid body[10] and has been shown to act as a chemoreceptor[11]. We have destroyed the area postrema of the rat and report here the effect of this operation on the blood pressure.

Male Sprague-Dawley normotensive rats and spontaneously hypertensive (SH) rats of the strain developed by Okamoto and Aoki[12] were used. The destruction of the area postrema was performed by sight through the occipital foramen by thermocoagulation. The procedure has been described in detail previously[13]. With the exception of thermocoagulation, the sham operation was exactly similar to the true operation. The blood pressure in unanaesthetised rats was measured indirectly by a tail cuff method[13] and in anaesthetised animals (pentobarbital, 40 mg kg^{-1}, i.p.) directly from the carotid artery.

In 1 week the ablation of the area postrema induced an elevation of blood pressure both in initially normotensive (Fig. 1) and in SH rats (Fig. 2). Five weeks after the operation the blood pressure of animals with the area postrema destroyed was still greater than that of the controls. Although the rats were accustomed to the blood-pressure measurements before the operation, most of them were somewhat excited at the start of each measurement, that is for the first 2 to 3 min. At 1 week the first recordings in normotensive controls were 7±2 mm Hg ($n=15$) higher than the stabilised values 3 to 4 min later (Fig. 1), whereas in the area postrema ablated rats, the initial values were 17±3 mm Hg ($n=18$) higher than the stabilised ones. In SH rats, the corresponding differences were 9±4 mm Hg ($n=14$) and 30±5 mm Hg ($n=19$), (Fig. 2). In sham-operated rats the greatest difference between the first recordings and the stabilised value was 15 mm Hg, but in rats with the area postrema destroyed differences up to 60 mm Hg were measured. The initial pressure recordings remained higher than the later ones for at least 2 weeks. During the first measurement procedures, some of the operated rats died of pulmonary oedema. Shortly before death in SH rats, values up to 270 mm Hg, and in initially normotensive rats up to 200 mm Hg, were measured. No such blood pressure elevations or sudden deaths occurred in the sham-operated rats.

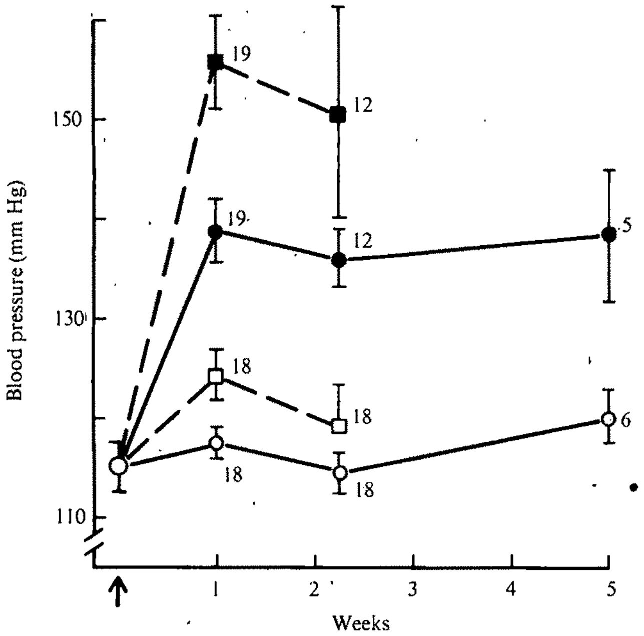

Fig. 1 Influence of the ablation of area postrema (■,●) and sham operation (□,○) on the blood pressure of normotensive rats. – – –, Values recorded during the initial 2 to 3 min period of the measurement procedure; ——, the following, stabilised values. Vertical bar, s.e.m. The number of rats is given on the figure.

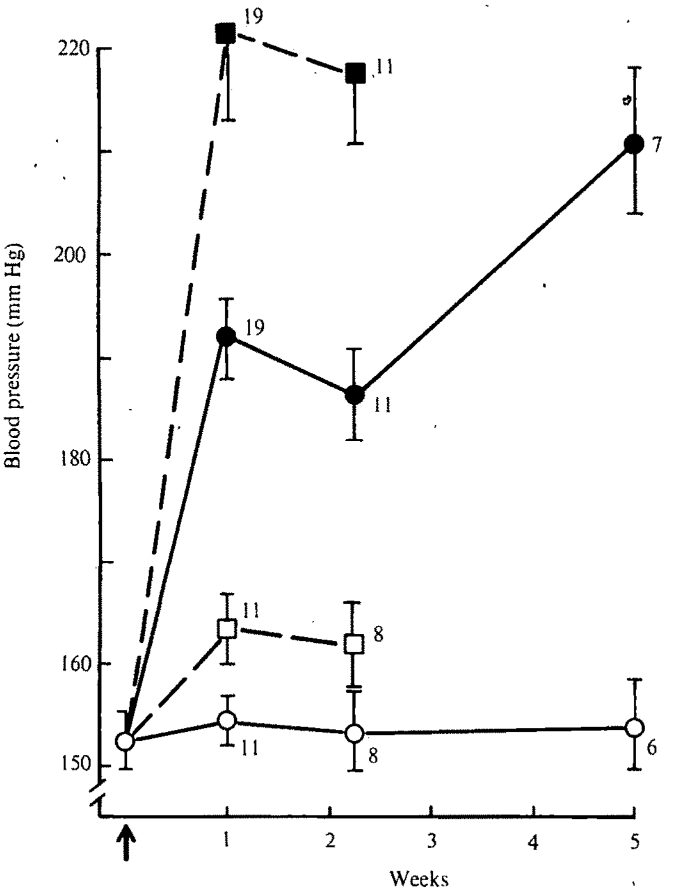

Fig. 2 Influence of the ablation of area postrema (■,●) and sham operation (□,○) on the blood pressure of spontaneously hypertensive rats. Symbols as in Fig. 1.

About 3 weeks after the destruction of the area postrema the initially normotensive rats also showed an elevated blood pressure during anaesthesia (sham operated, 126±8 mm Hg ($n=9$); area postrema ablated, 147±6 mm Hg ($n=11$), $P<0.05$).

The area postrema may exert a tonic inhibition on the blood pressure in the rat as its ablation induced an elevation of the blood pressure lasting at least 5 weeks. The area postrema might also be involved in the feed-back control of blood pressure as, in the absence of this region, very high blood pressures were induced by a stress situation, that is, by the recording of blood pressure.

Mechanism of the Viscoelastic Deformation of Collagenous Tissue

THE purpose of the experiment reported here was to examine the striking observation of Rigby *et al.*[1] that for collagenous tissue the thermally activated process controlling mechanical relaxation changes abruptly at the body temperature. For rat tail tendon it was observed[1] that below 37° C the process is entropy activated: the activation energy $\Delta H=0$. Above 37° C, Rigby *et al.*[1] conclude that ΔH is large although their

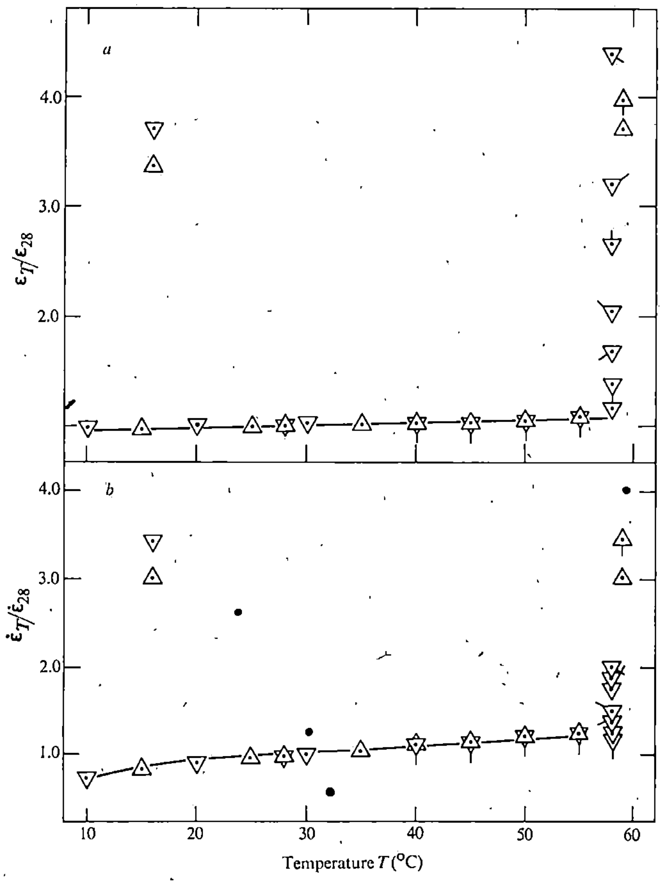

Fig. 1 Temperature dependence of normalised isochronal strain (*a*) and isochronal strain rate (*b*) at $t=20$ s for two specimens of digital tendon. Repeated experiments at a given temperature are indicated by the pips on the triangles, beginning with pip downwards for the second experiment and progressing clockwise by 60° for each successive experiment. Tendons studied under constant loads of 0.72 kg (male, 55 yr) and 0.30 kg (female, 89 yr). *a*: ▽, Male, $\varepsilon_{28}=1.40\%$; △, female, $\varepsilon_{28}=1.42\%$. *b*: ▽, Male, $\dot{\varepsilon}_{28}=5.81\times10^{-3}\%\ \text{s}^{-1}$; △, female, $\dot{\varepsilon}_{28}=4.00\times10^{-3}\ \%\ \text{s}^{-1}$.

experiment does not yield a quantitative result. The result is paradoxical in two ways. First, entropy activation, although feasible conceptually, is essentially unknown in nature. Second, is it plausible that the rate process should change in such a profound way right at the body temperature? We have now resolved both paradoxes.

The measurements were made on human flexor digitorum sublimus tendon *in vitro*. The specimen was mounted in a creep apparatus in which it could be subjected to a constant tensile load, and the tensile strain measured as a function of time of application of load, *t*. The specimen was immersed in 0.9% saline solution buffered to *p*H 7 which was maintained at a constant temperature in the range 10° C to 60° C. Figure 1 shows data for two specimens, one from a male of age 55 yr and the other a female of age 89 yr. The strain at $t=20$ s observed at *T*, ε_T, is divided by the strain at $t=20$ s observed at 28° C, ε_{28}, and plotted against *T* in Fig. 1*a*. It will be seen that (1) there is no discontinuity in the region of 37° C; (2) the data for both specimens are in excellent agreement; and (3) there is a transition at 58° C. The temperature dependence of the creep rate $\dot{\varepsilon}_T$ supports these conclusions. This is illustrated in Fig. 1*b* in which $\dot{\varepsilon}_T/\dot{\varepsilon}_{28}$ is plotted against *T*.

It may be concluded that for digital tendon there is no clear evidence for a change in rate process at 37° C; however, in order to test further the conclusion of Rigby *et al.*[1] that $\Delta H=0$ below 37° C we measured ΔH at 28° C by observing the change in creep rate induced by a small abrupt change of temperature (*T*-jump experiment). It follows from the theory of reaction rates[2,3] that if during a creep experiment the temperature is changed abruptly from T_0 to T at time t' and if $\dot{\varepsilon}_{T_0}$ and $\dot{\varepsilon}_T$ are the measured strain rates at T_0 and T at time t', then

$$\dot{\varepsilon}_T/\dot{\varepsilon}_{T_0}=\exp[(\Delta H/R)\,(1/T_0-1/T)] \tag{1}$$

Hence,

$$\ln\,(\dot{\varepsilon}_T/\dot{\varepsilon}_{T_0}) = (\Delta T/RT\,T_0)\,\Delta H \tag{2}$$

in which $\Delta T=(T-T_0)$ and R is the gas constant. In our experiment a number of *T*-jumps were performed from a fixed $T_0=28°$ C. According to equation (2) a plot of $\ln(\dot{\varepsilon}_T/\dot{\varepsilon}_{T_0})$ against $\Delta T/RT\,T_0$ should be linear and of slope ΔH. In each experiment the temperature was changed at a time $t'=60$ s after application of the stress. Fig. 2 shows results for the two specimens already described and a specimen taken from a male of 21 yr. It will be seen that the data for all three specimens are in good agreement and yield a finite value of ΔH, 12 kcalorie mol^{-1} at $T_0=28°$ C.

It follows from this result that for human digital tendon the conclusion of Rigby *et al.*[1] does not hold. The discrepancy between the two experiments is difficult to explain. It is certainly not due to the use of different mechanical techniques, stress relaxation[1] as opposed to creep. It is quite possible that since ΔH is low, and since Rigby *et al.*[1] studied many specimens (rat tail tendon breaks easily in saline solution and for this reason was not used in our experiments), the random scatter of results obscured the small temperature dependence of the stress relaxation modulus. This would explain the conclusions of Rigby *et al.* below 37° C. The cause of the sudden increase in the temperature dependence of stress relaxation modulus above 37° C observed by Rigby *et al.*[1] in rat tail tendon is unexplained. It could be due to the age of the tendon, since their specimens were taken from animals of age approximately 3 months.

A complete description of our work will be presented elsewhere including a study of the shrinkage transition at 58° C using the *T*-jump technique. This transition is rate activated with $\Delta H\sim250$ kcalorie mol^{-1}. It is our belief that for pseudo-first order transitions of this type and also for mechanical relaxation the *T*-jump technique is of considerable potential

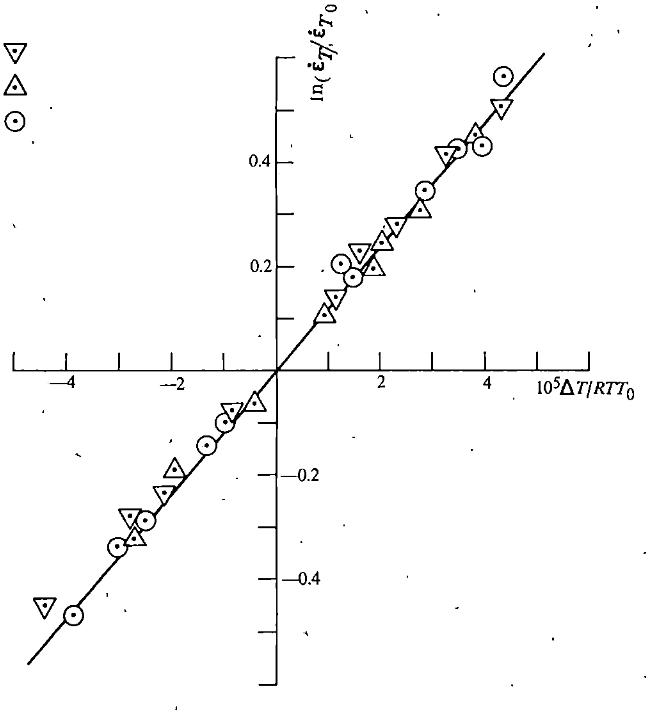

Fig. 2 Dependence of ln $\dot{\varepsilon}_T/\dot{\varepsilon}_{T_0}$ for three specimens of digital tendon on $\Delta T/RT\,T_0$. Straight line drawn according to equation (2) with $\Delta H=12$ kcalorie mol^{-1}. Tendons studied under constant loads of 0.72 kg (male, 55 yr (▽)), 0.30 kg (female, 89 yr (△)) and 0.76 kg (male, 21 yr (⊙)). $T_0=28°$ C.

for the study of biological systems. The linear viscoelastic techniques such as time–temperature superposition, which have found wide application for determining ΔH in synthetic polymers[4,5], are not applicable to biological systems. The strength of the *T*-jump technique is that even when the structure of the specimen changes during the deformation process (as it does in tendon[6]) the activation energy may still be determined since the creep rates $\dot{\varepsilon}_{T_0}$ and $\dot{\varepsilon}_T$ are determined at the same structure: that which occurs at the time of the *T*-jump. The technique is also accurate for low values of ΔH when superposition (as in the experiments of Rigby *et al.*[1]) becomes inaccurate.

Ion Beam Etching of Red Blood Cells and Latex Spheres

ION etching techniques have recently been utilised in attempts to reveal subsurface cell structures in the scanning electron microscope[1–7]. There has, however, been some difficulty in distinguishing intracellular structures from artefacts produced by the ion etching process. This inability to distinguish cellular structures from features produced by the ion beam suggests that a better understanding of the ion etching process as it is applied to organic material is required before this technique can be applied to the recognition and investigation of biological cell types and structure. In our study we examined the etch effects produced in normal red blood cells and homogeneous latex spheres by a variety of ion beam etching conditions.

Initial glow discharge ion etching studies of red blood cells showed that the etched red cell consisted of cone-like or filament-like structures[1]. Later studies[2,5–7] demonstrated that these filament-like structures and similar ridge-like features found in other etched cells[2–6] and tissues[7] were produced by the ion etching process[2]. The presence of these cone-like structures in ion etched cells and tissue has hindered the identification of cellular components. The study reported here was carried out to determine the ion etching conditions which reduce cone formation in red blood cells and homogeneous latex spheres.

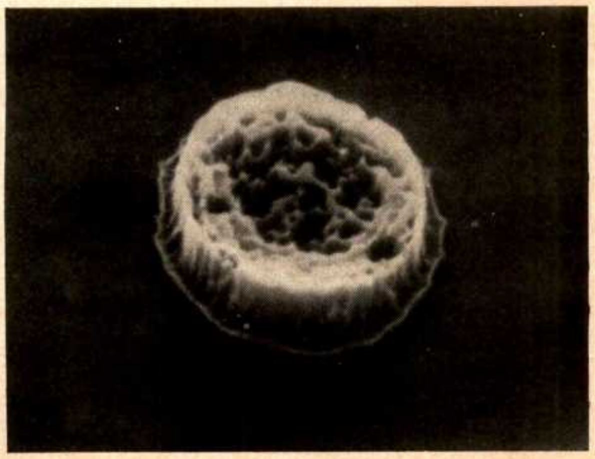

Fig. 1 Normal red blood cell ion beam etched by a 6 kV argon ion beam at 90° angle of incidence for about 25 min.

The red cell fraction of normal whole blood was washed in an isotonic phosphate-buffered medium (10 mM KCl, 141 mM NaCl, 1 mM $MgCl_2$, 1.3 mM $CaCl_2$, 0.8 mM NaH_2PO_4, 5 mM Na_2HPO_4 at *p*H 7.4, 300 mOsm) and fixed for 30 to 60 min in 0.5% phosphate-buffered glutaraldehyde, *p*H 7.4, 320 mOsm. The cells were then washed in deionised water and allowed to settle from a droplet of water onto a silicon disk. Care was taken that air drying did not occur during this time or during subsequent procedures. Dehydration was carried out by bathing the cells in 20, 50, 70, 90 and 100% ethanol solutions and 50 and 100% amyl acetate solutions for 5 min periods. The cells were taken directly from the 100% amyl acetate solution and critical point dried in carbon dioxide.

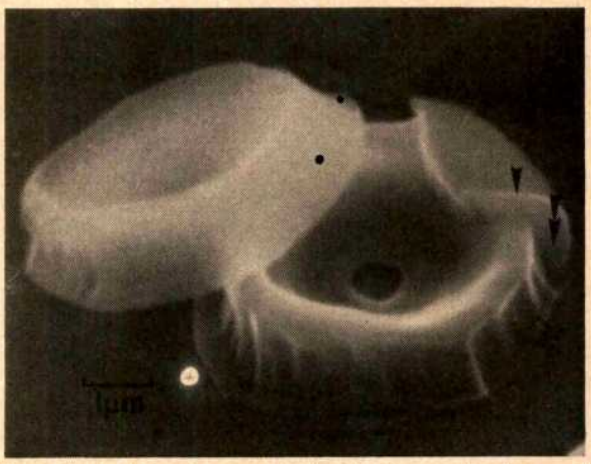

Fig. 2 Red cell ion beam etched by 17 kV argon ion beam with 90° angle of incidence for 3 min. A portion of the bottom cell which was shielded from the ion beam is unetched.

Styrene divinylbenzene copolymer latex spheres, 4 to 8 µm in diameter, were obtained from the Dow Chemical Company. The latex spheres were dispersed in deionised water, deposited on a silicon disk and air dried.

Ion beam etching was carried out in the specimen chamber of an ETEC Autoscan scanning electron microscope using an ETEC ion beam etching device with argon gas. The ion beam had an estimated diameter of 2 mm and a 2.3° beam divergence. The specimen was positioned about 1 inch from the ion gun aperture. Ion accelerating voltages of 5 to 20 kV with ion currents of 0.5 to 20 µA, respectively, were used for etching, The angle of incidence was maintained at 90° and etching times ranged from 1 to 30 min.

After etching, the red cells and latex spheres were coated with thin films of carbon and gold or gold-palladium and examined in the scanning electron microscope at 20 kV.

Red blood cells etched by a 6 kV argon ion beam had a very irregular surface characterised by cone- or ridge-like structures (Fig. 1) similar to those seen in cells etched by 1 to 4 kV argon ion beams[2,6]. There has been some indication in previous studies that the texture of the etched cell surface becomes smoother as the ion beam accelerating voltage increases[2]. The change in the texture of the etched cell surface with increasing ion accelerating voltage can be seen by comparing the cell in Fig. 1 with the cells in Fig. 2 which were etched by a 17 kV argon ion beam. Although the cells in Fig. 2 lacked much of the surface structure present in the cells in Fig. 1, the cells in both figures had similar groove-like features along their perimeter. These grooves were always found to be oriented in the direction of the ion beam.

The configuration of the cells in Fig. 2 during etching was such that a portion of the bottom cell was shielded from the ion beam. It is possible to see a cross-section of the portion of the cell that remained unetched. The shape of the etched sections of the cells suggests that different amounts of material were removed from different areas of the cells. It seems that less material has been removed from areas where the ion beam intersected the cell surface at 90° (indicated by single arrow) than from areas where the ion beam had about a 45° angle of incidence with the surface of the cell (double arrow).

The variation in the sputtering yield (number of atoms removed for each incident ion) with angle of incidence suggested in Fig. 2 is similar to the results of earlier studies of ion beam etching of metals[8]. The shapes of etched metal spheres inserted into ion beams demonstrated that the sputtering yield was a minimum at 90°, increased to a maximum at from 20° to 40°, and decreased again at grazing incidence.

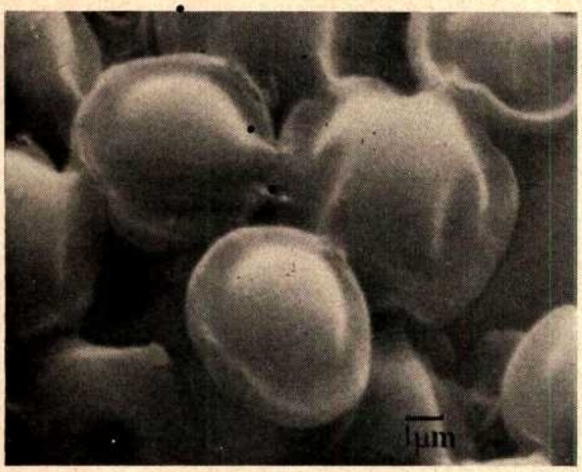

Fig. 3 Latex spheres etched by a 17 kV argon ion beam at 90° angle of incidence.

The effects of the change in sputtering produced by a change in angle of incidence along a curvilinear surface can also be seen in etched latex spheres (Fig. 3). Ion beam etched latex spheres are comparable to metal spheres which were ion beam etched in earlier studies[8]. The surfaces of the etched latex spheres had a smooth texture similar to that of red cells etched under similar conditions (Fig. 2) and occasionally had groove-like features somewhat similar to the features along the perimeter of the etched red cells.

The results of this study demonstrate that cone- and ridge-like structures present in red cells etched by relatively low voltage (1 kV to 6 kV) ion beams are reduced as the ion accelerating voltage is increased (for example, to 17 kV). The results further demonstrate that the shapes of red blood cells and homogeneous latex spheres etched with ion beams are comparable and can be explained by the change in the sputtering yield with the variation of the angle of incidence along the red cell and latex sphere surface. This relationship between sputtering yield and angle of incidence is similar to that determined earlier for inorganic materials. The results of the red cell etching are consistent with the view that the normal red cell is homogeneous, having no distinct subsurface structure resolvable in the scanning electron microscope. Work now in progress is using the ion beam etching technique to study the structure of nucleated and parasitised red cells.

Optically Detected Conformational Changes in Haemoglobin Single Crystals

THERE is considerable X-ray evidence that the haem stereochemistry is different in oxy- and deoxyhaemoglobin[1-3]. This structural change is an important part of the oxygenation process, because it is believed to induce conformational changes in the surrounding protein that are responsible for cooperativity. We have investigated conformational changes in the haem region by measuring polarised absorption spectra on single crystals. Using this technique we have detected changes in porphyrin plane orientation associated with an alteration of the ligand, spin, and oxidation state of the haem iron, factors which influence haem stereochemistry. Our results not only show for the first time that contacts between the porphyrin and amino acid side chains change upon oxygenation, but they are also consistent with the Hoard-Perutz hypothesis on the nature of the stereochemical trigger[1-3].

Crystals of horse oxyhaemoglobin, carbonmonoxyhaemoglobin, and methaemoglobin were prepared according to Perutz[4], except that the oxy and carbonmonoxy forms were crystallised at 4° C in order to minimise oxidation to methaemoglobin. Crystals of cyanide, azide, fluoride, and formate complexes were formed by diffusing the ligand into the methaemoglobin crystal. The deoxy form was prepared by dithionite reduction of methaemoglobin crystals previously modified with bis(N-maleimidomethyl)ether (BME)[5]. Single crystal spectra were measured over a wide wavelength range (230–1,200 nm) with plane-polarised light incident normal to the (001) face of the horse haemoglobin crystal[4] of space group C2. The measurements were made with a microspectrophotometer similar to the one previously described[6].

The important experimental parameter of the single crystal spectrum is the polarisation ratio. It is defined at each wavelength as the ratio of the optical density measured with the electric vector of the plane-polarised light aligned parallel to the *b* crystal axis to the optical density measured with the electric vector parallel to the *a* crystal axis. The polarisation ratio in the purely haem absorption region depends only on geometric factors. These are the molecular directions of the haem complex in which plane-polarised light is maximally absorbed and the orientation of these directions with respect to the *a* and *b* crystal axes. For the intense Soret band near 400 nm these molecular directions are very accurately described in all derivatives by a plane parallel to the mean plane of the 24 porphyrin ring atoms. This means that no light is absorbed for the component of the electric vector perpendicular to the porphyrin plane, while all directions contained in this plane show equal absorption. This planar-absorber behaviour for the Soret band has been established from the excellent agreement of the optically-determined porphyrin plane orientation[7–9] (Makinen and Eaton, unpublished) with that found by X-ray diffraction[10–14] and electron paramagnetic resonance[15] studies on a variety of haem protein crystals. Thus, we interpret differences in Soret polarisation ratio among haemoglobin derivatives as arising from differences in porphyrin plane orientation.

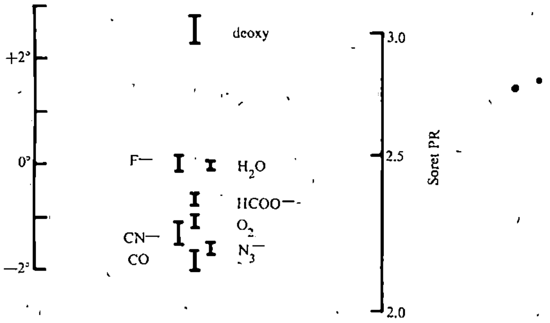

Fig. 1 Soret polarisation ratio and relative porphyrin plane orientation in horse haemoglobin derivatives. The uncertainties represent the average deviation from the mean of measurements on at least two crystals. The minimum angle between porphyrin plane normals, φ, is calculated from equation (1) and is relative to the porphyrin normal of (aquo) methaemoglobin. The following abbreviations are used: deoxy (deoxyBMEhaemoglobin), H_2O (aquomethaemoglobin), O_2 (oxyhaemoglobin), CO (carbonmonoxyhaemoglobin), CN^- (cyanomethaemoglobin), F^- (fluoridomethaemoglobin), $HCOO^-$ (formatomethaemoglobin), N_3 (azidomethaemoglobin).

Our results are summarised in Fig. 1. The scale at the right is the average polarisation ratio for the Soret band. The scale at the left shows the minimum change in orientation of the porphyrin plane that can account for the observed change in polarisation ratio. The angles are referred to the porphyrin normal of methaemoglobin and are calculated from the relation

$$\varphi_{ij}=\arctan (PR)_i^{\frac{1}{2}}-\arctan (PR)_j^{\frac{1}{2}} \qquad (1)$$

where $(PR)_i$ and $(PR)_j$ are the Soret polarisation ratios for the ith and jth derivatives. In deriving this expression we have assumed D_2 (222) symmetry for the orientation of the four porphyrin planes in all derivatives. This symmetry is exact for methaemoglobin within the experimental errors of both the electron paramagnetic resonance results[15] and the 2.8 Å atomic coordinates provided to us by M. F. Perutz. It is important to note that any deviation from D_2 symmetry for either the ith or jth derivatives will result in an increased absolute value of φ_{ij} for either α or β haems, or both. If we assume, for example, that only α or only β haems change orientation, then the absolute values of φ_{ij} are doubled. Also, changes in porphyrin plane orientation can be assumed to take place relative to axes fixed within the subunits since X-ray data[4,16,18] show that the quaternary structures of methaemoglobin, azidomethaemoglobin, oxyhaemoglobin, carbonmonoxyhaemoglobin, and deoxyBMEhaemoglobin are essentially identical.

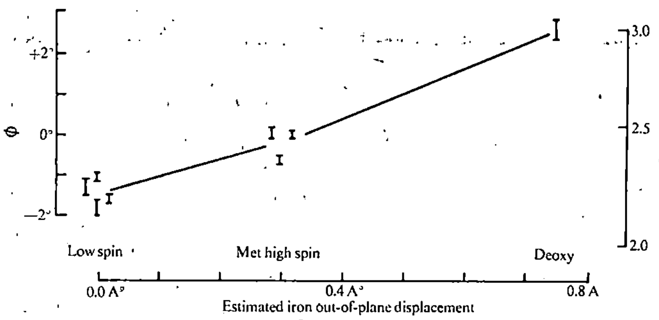

Fig. 2 Soret polarisation ratio and relative porphyrin plane orientation against estimated displacement of the iron from the mean porphyrin plane. The displacement in horse methaemoglobin and deoxyhaemoglobin is 0.3 Å and 0.75 Å, respectively[2]. To assign approximate values for the other derivatives we have appealed to the X-ray data on sea lamprey cyanomethaemoglobin[19] and the predictions from small molecule structures[3]. Thus, we use 0.75 Å, 0.3 Å, and 0.0 Å for ferrous high spin (deoxy), ferric high spin (H_2O, F^-, $HCOO^-$), and ferric or ferrous low spin derivatives (O_2, CO, CN^-, N_3), respectively. The polarisation ratios (PR) are shown as clustered around these points for clarity.

Our interpretation of the variation in Soret polarisation ratio among haemoglobin derivatives receives strong support from X-ray results. The minimum angle between the porphyrin normals of methaemoglobin and deoxyhaemoglobin is calculated to be +2.5° (Fig. 1). This value is consistent in both sign and magnitude with the movement of the porphyrin planes detected by difference Fourier studies[2,16] (M. F. Perutz, personal communication). The only other haemoglobin derivative to be examined in the liganded quaternary structure at high resolution by X-ray methods is horse carbonmonoxyhaemoglobin. Here again the optical and X-ray results are in agreement (E. G. Heidner, personal communication). Oxyhaemoglobin has not yet been studied at high resolution because the crystals are almost completely oxidised to methaemoglobin by the end of the X-ray exposure[2]. The much smaller crystals used in our optical experiments contained less than 20% methaemoglobin. We find that the porphyrin planes tilt at least 3.5° in the transition from oxyhaemoglobin to deoxyhaemoglobin constrained by BME to remain in the liganded quaternary structure. This rotation corresponds to a displacement of peripheral porphyrin atoms of at least 0.3 Å. Since there are a large number of non-bonded interactions between the protein and porphyrin—there are approximately sixty atoms of the protein less than 4.0 Å from the porphyrin[20]—such a displacement must be accompanied by a movement of amino acid side chains in contact with the porphyrin ring. Thus, our observation of a change in orientation of the porphyrin plane supplies the first experimental evidence for a change in porphyrin-protein contacts upon oxygenation.

Hoard[1,3] and Perutz[2,16] have suggested that the important structural change initiating cooperativity in the protein is a shortening of the distance between the haem-linked histidine and the porphyrin plane upon oxygen binding. The histidine is covalently bonded to the iron, so that the principal part of this movement arises from the shift of the iron from 0.75 Å out of the plane in deoxyhaemoglobin to an essentially coplanar position in oxyhaemoglobin. This histidine-porphyrin movement, referred to as the stereochemical trigger, is expected to force changes in the contacts between the porphyrin and amino acid side chains[16]. From this stereochemical trigger hypothesis we would predict that derivatives with similar iron out-of-plane displacements should have similar porphyrin orientations. As a test of this prediction we have plotted our orientation results against the estimated iron out-of-plane displacement (Fig. 2). The data do indeed neatly divide into three classes according to the iron-porphyrin distance. This result is not only consistent with the postulated importance of the histidine-porphyrin movement, but it also suggests that this stereochemical change is transmitted to the protein through an alteration in porphyrin-protein contacts.

We thank Dr James Hofrichter, Mr Walter W. Stewart, and Professor David C. Phillips for helpful discussions. We also thank Dr Max F. Perutz for providing us with unpublished atomic coordinates of horse haemoglobin.

Fluoridated Hydroxyapatite Solubility and Caries Formation

SINCE the early observations[1] on reduction of caries with increasing fluoride concentrations in drinking water, the tacit assumption was made that fluoride incorporated in dental enamel acts as a cariostatic agent. An appealing explanation for the possible mechanism involved is based on the nature of the enamel mineral of which hydroxyapatite (OHA), $Ca_5OH(PO_4)_3$, is considered to be the prototype. Replacement of fluoride for the hydroxyl would yield fluorapatite (FA) which has a lower solubility. Analyses of surface layers of enamel, however, show that the fluoride contents are far below the level expected for FA. It is relevant then to ascertain to what extent partial substitution of the fluoride for the hydroxyl group in HA affects its solubility.

In a recent publication[2] related to the anti-cariogenic effect of fluoride, Driessens reported calculated solubilities of the solid solutions $Ca_5(OH)_{1-x}F_x(PO_4)_3$ of which hydroxyapatite and fluorapatite are the end members. The subscript x is the degree of substitution of fluoride for hydroxyl and its numerical value varies from 0 (for HA) to 1 (for FA). His calculations are based on the standard free energies of formation ΔG_f° (free enthalpies in Driessens's terminology) reported by Duff[3]. These latter values are open to question because their calculation was based on analytical data for systems which were not demonstrated to be at equilibrium and because analytical data were used to calculate ΔG_f° values for compounds that were not formed in the experimental systems.

We have prepared a series of solid solutions with degrees of fluoride substitution, x, estimated chemically, was 0, 0.13, 0.24, 0.41, 0.57, 0.81, 0.89 and 1; details about the preparation of these compounds, involving a very slow precipitation process, will be published elsewhere. The solid-solution nature of these samples was verified by crystallographic techniques. Thus, a linear decrease in the magnitude of the unit cell parameter, a, was obtained with increasing values of x. As shown below, however, the thermodynamic properties of these compounds are slightly different from those expected for an ideal solid solution and, as should be anticipated[4], these small differences significantly affect their solubility behaviour.

We report here the solubility of these compounds obtained by equilibrating them for more than 1 month with a series of dilute phosphoric acid solutions at 37° C. For a given member of the series we can express its solubility product constant, K_x, as $K_x=(Ca^{2+})^5(OH)^{1-x}(F^-)^x(PO_4{}^{3-})^3$ in which parentheses indicate activities. The ionic activities in the liquid phase can be calculated by iterative procedures similar to those previously reported[8]. Introducing the definition of the ionisation constant of water, K_w, it can be shown that $\log (H+)^3 (PO_4{}^{3-})=1/3 \log K(x,w) -5/3[\log(Ca^{2+})(OH^-)^2+x/5 \log (H^+)(F^-)]$ in which $K(x,w)=K(x) K(x)^{(9+x)}$. Thus, a plot of the quantity $-\log (H^+)^3(PO_4{}^{3-})$ against the quantity $-x/5 \log (H^+)(F^-) -\log(Ca^{2+})(OH^-)^2$ should yield a straight line with a slope of $-5/3$. The plots for the various compounds will be displaced depending on the value of x but the slopes should be the same. The results of the analyses of the aqueous phase after equilibration were used to obtain the plots shown in Fig. 1. It is apparent that the data yielded a series of straight lines with the anticipated slope, within experimental error. These results constitute verification of the equilibria between the solid and liquid phases involved.

In Table 1 we report the values of K_x for the various degrees of substitution. A polynomial fit to these data (degree of determination 0.95) shows a minimum in K_x for a degree of substitution of 0.56, implying a minimum in the ΔG_f° for such a composition. The calculations reported by Duff[3] do not show a minimum. This minimum, experimentally determined, could be anticipated on the basis of the disordered structure[5,6] of hydroxyapatite and the hydrogen bonding[7] of the hydroxyl

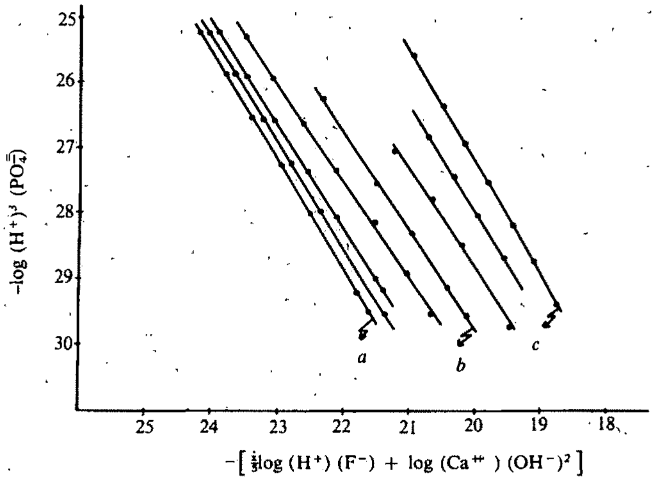

Fig. 1 Plots of quantities derived from solution compositions at equilibrium (see text). The slopes of the various lines (5/3 within experimental error) satisfy the equilibrium requirements. *a*, FA; *b*, $x=0.405$; *c*, OHA.

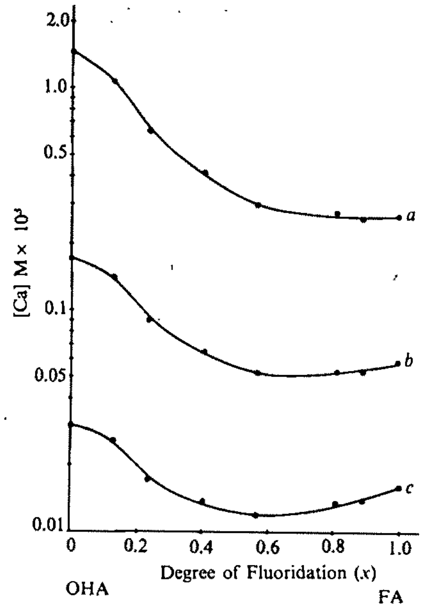

Fig. 2 Solubility of the solid solutions (expressed as molarity of calcium) as a function of the degree of fluoride substitution. Results are shown for, *a*, *p*H 5; *b*, *p*H 6; *c*, *p*H 7.

group to fluorine occurring in the structure. Both of these features would make their greatest contribution to the stability of the crystalline lattice at a degree of substitution of about 0.5.

Considering the constituent ions of the solid solutions plus the ion pairs[8] $CaH_2PO_4^+$ and $CaHPO_4^0$ as the only species present in the equilibrated solution, we have constructed the plots shown in Fig. 2. On the ordinate are plotted the calcium concentrations in the aqueous phase maintained by the solid solution at equilibrium. Therefore, the curves reflect the variation of the solubility as a function of the degree of substitution. Values for x in the order of 0.05 are usually obtained for the surface enamel from fluoridated areas by assuming that the fluoride is uniformly distributed in the enamel sample. Contrary to the assertion by Driessens[2], the plots show that substitutions of this order (0.05) have very little effect on the solubility of hydroxyapatite. The fluoride concentration gradient is very steep[9,10], however, in the first few micrometres of enamel. Incidentally, this gradient is already established before tooth eruption; the fluoride concentrations in enamel from fluoridated areas are of a pre-eruptive origin[10] and not as a result of topical effects as Driessens has suggested[2]. In fact, recent work[11] on analyses of very shallow biopsis (0.2–0.4 µm) indicates that it is not unreasonable to consider that the degree of substitution at the very surface of the enamel may approach a value close to 0.5. If this is the case, our results indicate a significant reduction in solubility which undoubtedly could contribute to the cariostatic effect of fluoride. Important as this reduction in solubility may be in relation to caries prevention, there are other aspects that should be considered. For example, fluoride intake at early ages (while teeth are in the formative period) produces shallower pits and fissures in occlusal surfaces[12]. Furthermore, it appears that the electrochemical properties of the surfaces of fluoridated apatites are different from those of hydroxyapatite. Thus, it has been reported[13] that the adsorption of salivary proteins is significantly different between these two kinds of compounds. We have verified this behaviour in our own laboratories. It is conceivable therefore that the selective formation of permselective coatings induced by the fluoridated surfaces of enamel may enhance the protection of the tooth structure.

Table 1 Values of K_x for Various Degrees of Substitution

Degree of substitution (x)	Solubility product constant (K_x)
0.0	$7.36 \pm 0.93 \times 10^{-60}$
0.13 ± 0.004	$2.13 \pm 0.11 \times 10^{-60}$
0.24 ± 0.01	$8.44 \pm 2.59 \times 10^{-62}$
0.41 ± 0.01	$2.32 \pm 0.81 \times 10^{-62}$
0.57 ± 0.02	$6.55 \pm 2.17 \times 10^{-63}$
0.81 ± 0.03	$5.87 \pm 1.30 \times 10^{-62}$
0.89 ± 0.03	$7.99 \pm 0.90 \times 10^{-62}$
1.00 ± 0.03	$3.19 \pm 0.14 \times 10^{-61}$

Reversal by Narcotic Antagonist of a Narcotic Action elicited by a Conditional Stimulus

THERE is considerable evidence to indicate that learning is important in narcotic dependence[1]. However, there has been little animal research into the mechanism of the interaction between environmental stimuli and drug action which maintains dependence. In morphine-dependent rats[2] and monkeys[3] conditional stimuli previously associated with withdrawal can elicit physiological disturbances characteristic of narcotic withdrawal. Also, during withdrawal the conditional stimuli previously associated with morphine substitution can elicit blockade of morphine withdrawal[4]. In an experiment by Roffman *et al.*[4], after a number of pairings with morphine injections, a neutral stimulus (bell) elicited a blockade of withdrawal hypothermia, a task normally accomplished by morphine itself. It was then suggested that there is an overlap between the brain mechanisms sensitive to morphine action and those affected by conditional stimuli[5]. Therefore, repeated pairing of hyperthermic effects of morphine with the stimulus-induced neural activity results in the conditioning of the former to the latter. We reasoned that if the brain activity due to a conditional stimulus evokes activity of the morphine receptors, a morphine antagonist should reverse the effectiveness of that stimulus in mimicking the morphine action. To obtain evidence in favour of this hypothesis we used naloxone, a specific antagonist of morphine action[6].

We used male Long-Evans rats (200–250 g) housed individually in a room maintained at 21–23° C with lights alternating on a 12 h dark–light cycle. Food (Purina chow) and water were available *ad libitum* except during injections and when physiological measurements were being made. The rats were given two equally spaced injections of morphine sulphate daily in increasing doses until a maintenance dose was reached. The first injection consisted of 10 mg kg^{-1}, which was increased by 10 mg kg^{-1} every day, until the tenth day, when each injection consisted of 100 mg kg^{-1}. The rats were maintained at this dosage (200 mg kg^{-1} d^{-1}) for 3–5 d and then withdrawn. Each morphine injection was given in a well-lit room which was sound-attenuated and maintained at a constant temperature of 21° C. Each injection was paired with a bell which was turned on 1 min before the injection and turned off at the completion of that injection. After each injection, the rat was returned to its home cage away from the injection room.

During the withdrawal period of 24 h these rats were divided into three groups. One group (thirty-six rats) was not given any treatment during abstinence to obtain withdrawal hypothermia. A second group (six rats) was injected with morphine and exposed to the bell as during the addiction phase to serve as non-withdrawal controls. The third group (six rats) also continued to be injected and exposed to the bell as during the addiction phase. In this case, however, saline was injected instead of morphine sulphate to obtain the effect of conditioned stimuli during withdrawal from morphine. Thirty minutes after the last treatment, or after 24 h without treatment in the case of group 1, rectal temperature was measured by inserting a thermocouple probe 5 cm inside the rectum for 60 s. Following that measurement, the first group was divided into six subgroups (six rats each). One subgroup was then injected with naloxone (2 mg kg^{-1}), another with morphine (100 mg kg^{-1}), a third was exposed to the bell, and a fourth to the bell followed by naloxone given 10 min after the bell. The fifth group was given morphine followed by naloxone 30 min later. The last group was not given any treatment to serve as a control for withdrawal hypothermia.

It was previously established[4,5] that the bell paired with saline does not affect rectal temperature in non-addicted rats. Also, naloxone did not cause any change in temperature of the non-addicted rats.

Table 1 Effect of Conditional Bell and Morphine on Rectal Temperature of Morphine-dependent Rats during Abstinence

Treatment during 24 h abstinence*	*N*	Rectal temperature (°C)† mean ±s.e.
None	36	37.42±0.03
Bell and morphine‡	6	39.06±0.06
Bell and saline	6	38.06±0.06

The rats were addicted by repeated injections of morphine paired with bell.

* After a maintenance dose of 100 mg kg^{-1} (total daily dose of 200 mg kg^{-1}) the morphine injections were withheld for 24 h and one of the three treatments applied.

† Measured 30 min after the indicated treatment.

‡ Same dose as during maintenance (100 mg kg^{-1}).

Morphine injection reversed the withdrawal hypothermia and produced hyperthermia in these rats (Table 1) as was previously reported by others[7]. Exposure to the bell without morphine also reversed the withdrawal hypothermia as expected from our previous study[4,5]. In a pilot experiment, presentation of the bell during abstinence or after morphine injection had not affected rectal temperature of a group of animals which had been repeatedly exposed to a bell during addiction phase, which was not regularly paired with morphine injections.

Data summarised in Table 2 show the effect of naloxone on the rectal temperature of the addicted rats undergoing withdrawal. In these rats naloxone without any pretreatment produced slight hypothermia. However, when these rats were injected with naloxone after the bell, which itself increased rectal temperature by a degree, naloxone caused a severe decrease of that temperature. This effect of naloxone was similar to that seen after morphine injection in the addicted rats. Morphine caused marked hyperthermia in the abstinent rats. Naloxone injected after morphine caused a considerable decrease of temperature in these rats.

Table 2 Effect of Naloxone, Morphine or Conditional Stimulus Administered after an Abstinence Period of 24 h in Morphine-addicted Rats

Test treatment*	*N*	Rectal temperature§ mean (°C)±s.e.	Change‖ (° C)	*P*¶
None	6	37.00±0.08	—	—
Naloxone†	6	36.68±0.06	−0.32	<0.05
Bell	6	38.04±0.06	+1.04	<0.001
Bell+ naloxone	6	36.17±0.06	−1.87	<0.001
Morphine‡	6	38.87±0.21	+1.87	<0.001
Morphine+ naloxone	6	37.37±0.26	−1.28	<0.001

* Given 24 h after last morphine injection.

† 2 mg kg^{-1}, given interperitoneally.

‡ Same dose as during the maintenance regime (100 mg kg^{-1}).

§ Measured 30 min after last treatment.

‖ From their respective control given in third column. Naloxone, morphine or bell group is compared with none group, while bell+naloxone group is compared with bell-alone group and morphine+naloxone is compared with morphine-alone group.

¶Student's *t* test, two tailed.

Either injection of morphine or exposure to the bell caused hyperthermia in the abstinent rats. The rectal temperature of morphine-treated rats was, however, higher than that of rats exposed to the bell. A quantitative similarity between morphine and the bell is not justified because we used a large dose of morphine (100 mg kg^{-1}) and attempted no variation of bell intensity for comparison.

Our findings on the ability of conditional stimulus to mimic the counter-withdrawal effect of morphine are in accord with earlier findings on conditioning of the agonistic effects of morphine. According to Bykov[8], Devlov and Petrova in Pavlov's laboratory used physical stimuli to elicit conditional electrocardiographic changes associated with morphine injection. Collins and Tatum[9] serendipitiously discovered a conditional salivary reflex associated with morphine injection. Kleitman and Crisler[10] replicated conditioning of salivary-reflex using morphine as the unconditional stimulus. It should be pointed out that our observations are limited to abstinence hypothermia and therefore our conclusions may not be applicable to other signs of abstinence. In rats, hypothermia has been considered one of the most reliable signs of abstinence.

Narcotic antagonists are known to precipitate narcotic withdrawal. As far as we know, however, interaction of narcotic antagonist with the learned conditional effects of morphine has not been previously studied. The ability of naloxone to block the physiological responses evoked by conditional stimuli in the same manner as it blocks the unconditional morphine effects has both theoretical and practical implications.

Of theoretical importance is the suggestion from this study that the conditional stimulus may evoke activity in the brain pathways specifically sensitive to the agonistic actions of morphine and to morphine dependence. Alternatively, the common belief that naloxone acts only by displacing morphine from its receptor may be questioned. Rather, naloxone may exert an agonistic influence on brain substrates originally insensitive to naloxone but rendered sensitive by the actions of morphine. Other experiments showing the inability of narcotic agonists to reverse actions of narcotic antagonists[11–13] raise similar doubts about the hypothesised mode of action of narcotic antagonists. A recent report on the naloxone antagonism of analgesia produced by brain stimulation[14] supports this possibility of the direct action of naloxone.

The practical importance of this finding is related to the use of narcotic antagonists in the therapy of narcotic addiction. The current rationale behind the use of narcotic antagonists in the treatment of heroin addicts is that treatment with these drugs will result in the extinction of heroin consumption because of the blockade of the 'high' sought from agonistic effects of illicit heroin. Our data suggest that narcotic antagonists may also be valuable in extinguishing heroin habit associated with the conditional placebo effects of heroin-seeking behaviour. These effects have been considered to be major factors in relapse to the addiction in humans[1].

Survival of Common Bacteria in Liquid Culture under Carbon Dioxide at High Temperatures

MOLTON *et al.*[1] have reported that bacteria in liquid cultures survived exposure to normally lethal temperatures when heated in a high pressure CO_2 atmosphere. Because these results could influence planetary quarantine constraints, particularly for the planet Venus, and because no protection against thermal death by CO_2 has been reported previously, an attempt was made to verify their results.

In addition to the same strains of *Escherichia coli*, *Aerobacter aerogenes*, *Serratia marcescens*, and *Bacillus subtilis* used by Molton *et al.*[1], a thermophilic bacillus (YTG-2 S^r) and two genetically marked *E. coli* strains were tested. Initial experiments followed the methods for bacterial cultivation, CO_2 pressurisation, heating, and depressurisation described by Molton *et al.*[1], with the exception that YTG-2 S^r was grown at 65° C. Viability assays differed only in that dilutions beyond 10^{-6} were not used and duplicate rather than triplicate platings were made.

Stationary and log-phase cultures of *E. coli* B, *E. coli* K 12 S^r, *A. aerogenes*, YTG-2 S^r, *S. marcescens*, and *B. subtilis* were exposed to 160° C for periods of 3.5 to 22 h under 19.7 atm CO_2. No survivors were obtained. A less severe exposure to heat was also examined using stationary and log-phase cultures of *E. coli* B, *E. coli* B T-Pr-, and *B. subtilis*. No survivors were obtained with any of the three strains after exposure to 125° C for either 5 or 18 h under 9.5 atm CO_2 pressure.

Table 1 Effect of High Pressure CO_2 on the Survival of *E. coli* and *B. subtilis*

Organism	Pressure (atm)	Temperature ° C	Time (h)	Initial (Viable counts ml^{-1})	Final (Viable counts ml^{-1})	Survival (%)
E. coli B	9.5	22	1	2.7×10^9	3.4×10^9	125.9
E. coli B	19.7	22	1	2.7×10^9	3.3×10^9	122.2
E. coli B	19.7	15	18	2.7×10^9	3.1×10^9	114.8
B. subtilis	9.5	22	1	1.1×10^8	1.2×10^7	10.9
B. subtilis	9.5	22	1	1.4×10^8	4.7×10^7	33.6
B. subtilis	19.7	22	1	1.1×10^8	3.5×10^3	0.0032
B. subtilis	19.7	22	1	1.4×10^8	1.9×10^6	1.4
B. subtilis	19.7	15	18	1.1×10^8	0	0

Microscopic observation of *E. coli* B, YTG-2 S^r, *A. aerogenes*, and *S. marcesens* subjected to a high pressure CO_2 atmosphere heated at 125° or 160° C revealed that nearly 100% lysis had occurred with heating periods as short as 6 h. Cells of *B. subtilis*, however, did not lyse. The 30 min exhaust time used by Molton *et al.* (personal communication) was extended to 1 to 1.5 h in an attempt to reduce lysis. The slower exhaust rate neither increased survival nor reduced lysis significantly.

Since no survival was obtained at high temperatures and as the physical condition of heated cells did not improve with a very slow depressurisation rate, the effect of pressurisation and depressurisation without heating was examined. Cultures of *E. coli* B did not lyse or lose viability when exposed at room temperature (22° C) for 1 h at 9.5 or 19.7 atm CO_2 (Table 1). Exposure for 18 h at 15° C under 19.7 atm CO_2 did not decrease the viability of an *E. coli* B culture either. These results suggest that the pressurisation with CO_2 and subsequent depressurisation were not sufficient to kill unheated cells of *E. coli* B. In two separate experiments with late log-phase cultures of *B. subtilis*, survival decreased to 10.9% and 33.6% after 1 h exposure to 9.5 atm CO_2 at 22° C. At 19.7 atm CO_2, a 1 h exposure of *B. subtilis* cells at 22° C resulted in 0.0032% and 1.4% survival. No survivors were obtained when *B. subtilis* cultures were exposed to 19.7 atm CO_2 for 18 h at 15° C. Thus, with *B. subtilis*, high CO_2 pressure without heating was quite lethal.

In summary, we were unable to reproduce the results reported by Molton *et al.*[1] and suggest that additional studies are needed before conclusions can be reached regarding the thermal protection of bacteria by carbon dioxide at high pressures.

Production of Bladder Stones by Human T Mycoplasmas

SINCE the first isolation of human T mycoplasmas[1], their pathogenic role has remained controversial. These organisms, present in the urogenital tract of men and women, are unique among mycoplasmas in possessing urease[2]. They have recently been isolated from other mammals[3–5]. Bovine strains have

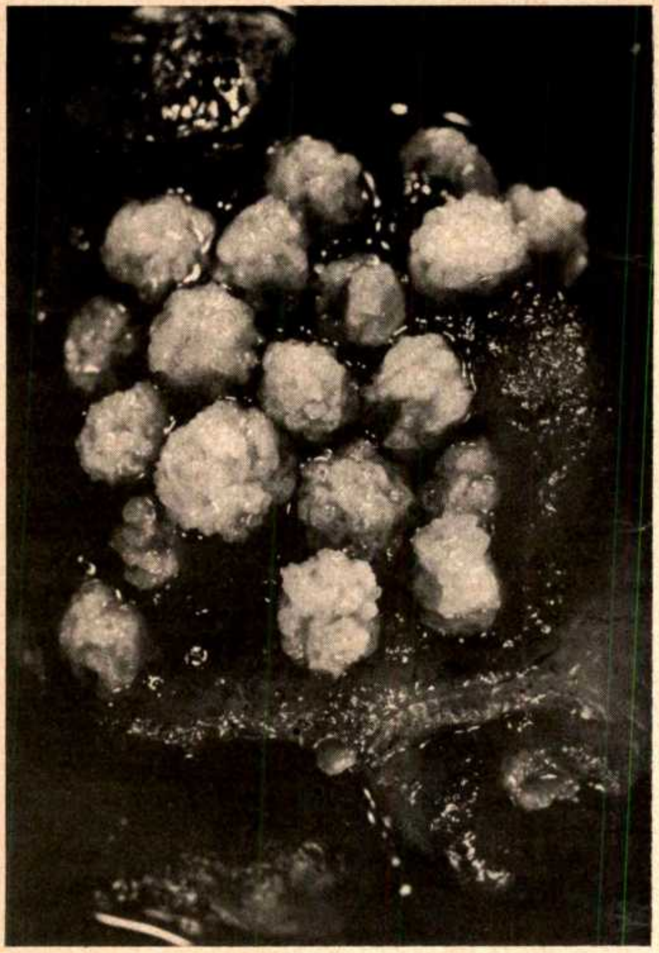

Fig. 1 Bladder stones from a rat killed 6 weeks after renal inoculation with T mycoplasma (×3).

caused experimental pneumonitis in calves[6] and mastitis in cattle. In the latter experiment, human T mycoplasmas were unable to produce mastitis[7]. Human T mycoplasmas have been implicated as causative agents of non-gonococcal urethritis in men and pelvic inflammatory disease, puerperal infection and reproductive failure in women[8]. Their true relationship to human disease, however, remains unknown, and until now they have never been reported to produce disease in experimental animals. We now report the production of bladder stones during experimental infection of rats by human T mycoplasmas.

The T960 strain of human T mycoplasma was grown aerobically at 37° C in trypticase soy broth containing 15% horse serum, 1.25% yeast extract, penicillin (1,000 units ml^{-1}), 0.1% urea and 0.002% phenol red (*p*H 6.0). After overnight culture, an alkaline *p*H change occurred (final *p*H 7.0–7.1). The culture was centrifuged (20,000*g* for 30 min at 4° C) and concentrated 100-fold by resuspending in the supernatant giving 10^6–10^8 colour changing units (CCU) ml^{-1}. Male Sprague-Dawley rats (250–400 g) fed antibiotic-free chow were infected by injecting 0.1 ml into the bladder lumen or renal medulla. They were killed 6 weeks later and examined and cultured for bacteria as previously described[9].

Bladder calculi developed in 78% of male rats after direct renal injection (Table 1). There was no difference in the incidence of stones when 10^6 and 10^8 CCU were used. No bladder stones formed after inoculation with concentrated T mycoplasma broth (*p*H 7.0) alone. The stones were 2–4 mm in diameter (Fig. 1), with up to thirty per rat. Crystallographic analysis showed all the bladder calculi to be essentially pure $MgNH_4PO_4.6H_2O$. All the eleven stones analysed were 100% $MgNH_4PO_4.6H_2O$ except one, which contained 1% carbonate apatite. Ten per cent of normal male and female rats of this strain form minute gravel deep in the renal pelvis. Such gravel was distinctly different from the bladder calculi which develop following T mycoplasma infection, as it was composed of calcium oxalate dihydrate and hydroxyapatite with no trace of $MgNH_4PO_4.6H_2O$. Renal gravel from two rats infected with T mycoplasmas was composed of pure $MgNH_4PO_4.6H_2O$. In none of the experiments with T mycoplasmas was there any effect on the incidence of renal gravel compared with uninfected controls.

Most rats with bladder stones had thickened bladders and dilated ureters. Hydronephrosis was present in one third of the rats. The kidneys showed tiny cortical scars with fibrosis and some round cell infiltration around the needle tract. Similar renal changes were seen following injection of broth only. No bladder thickening, dilated ureters or hydronephrosis was seen, however, in broth controls or rats injected with T mycoplasma which did not develop stones. There was no disease in the prostate or seminal vesicles. Urine, kidney and prostate cultures were negative for bacteria.

Stones formed in three of six rats as early as one week following renal inoculation. Female rats (200–220 g) failed to produce bladder stones (Table 1) and a similar sex difference has been noted in experimesntal tone formation[10]. Intravenous infection failed to produce stones; in males however, inoculation into the bladder lumen of males produced stones at the same high incidence as that seen following renal infection (Table 1).

While attempting to recover T mycoplasmas from the animals, we found a growth inhibitor for T mycoplasmas in renal homogenates similar to that described for large colony mycoplasma[11]. This inhibitor was present at 10^{-1} dilution but was absent on further dilution. No T mycoplasmas were detected in the urine, kidney or prostate of uninoculated rats. T mycoplasmas were isolated from urine and kidney cultures of rats which developed bladder stones following renal infection. A similar isolation rate was seen in infected rats which did not develop stones. Three of ten bladder stones washed extensively in phosphate buffered saline yielded T mycoplasmas on culture.

To determine whether viable organisms are necessary for stone formation, a group of rats was given erythromycin injections daily (80 mg kg^{-1}) for 7 d following renal inoculation with T mycoplasmas. This dose gave urine levels of erythromycin ten times the minimal inhibiting concentration for T960 *in vitro* (3.12 μg ml^{-1}). Erythromycin did not prevent stone formation (Table 1) although urine, kidney and prostate cultures were negative for T mycoplasmas. The implication that viable T mycoplasmas were not required for stone forma-

Table 1 Incidence of Bladder Stone Formation in Rats following Infection with T Mycoplasma

Group	Sex	Route of infection	No. of animals with stones/ Total No. in group
T mycoplasma	♂	Renal	49/63
Uninoculated	♂	Renal	0/17
T mycoplasma broth		Bladder	0/8
T mycoplasma	♀	Renal	0/9
T mycoplasma	♂	Intravenous	0/10
T mycoplasma	♂	Bladder	19/21
T mycoplasma + erythromycin treatment	♂	Renal	7/10
T mycoplasma, acetone killed	♂	Renal	16/20
T mycoplasma 100° C, 15 min	♂	Renal	4/10
P. mirabilis in T mycoplasma broth	♂	Renal	0/5
100° C, 15 min		Bladder	0/5
M. hominis	♂	Bladder	0/12

Rats were all killed 6 weeks after infection. Inocula for these experiments were as follows: T mycoplasma, 10^6–10^8 CCU per 0.1 ml; *P. mirabilis*, 10^9 organisms per 0.1 ml; *M. hominis*, 10^9 CCU per 0.1 ml.

tion was further examined by injecting rats with killed organisms. A culture of T mycoplasmas was centrifuged and resuspended in 33% acetone overnight. The organisms were then centrifuged and resuspended in complete T mycoplasma media (*p*H 7.1) to 0.01 of the original culture volume. Renal inoculation with 0.1 ml mycoplasmas killed in acetone produced bladder stones at the same high rate as with live T mycoplasmas (Table 1). Acetone treatment killed the T mycoplasmas and preserved minimal urease activity as measured by *p*H change. T mycoplasma killed by heat (100° C, 15 min) which had no urease activity still produced stones although at a lower incidence (Table 1) than organisms killed in acetone. Viable T mycoplasmas are thus not required for stone formation.

The observation that heat killed organisms caused stones suggested that T mycoplasmas might do so simply by providing a nidus. This was studied further with *Proteus mirabilis* which has a potent urease and causes $MgNH_4PO_4.6H_2O$ stones during urinary tract infection in rats[12]. *P. mirabilis*, grown in trypticase soy broth was centrifuged and resuspended to 10^9 organisms per 0.1 ml in T mycoplasma broth and then killed by heating at 100° C for 15 min. No bladder stones formed after inoculation of dead *P. mirabilis* (Table 1). The failure of heat killed *P. mirabilis* to cause stones suggests that the nature of the particulate matter may determine whether it can serve as a nidus for calculus formation.

Another mycoplasma species was then examined for stone forming ability to see whether this was a property limited to T mycoplasmas. *Mycoplasma hominis*, the other principal human urogenital mycoplasma, was grown in T mycoplasma media with 1% L-arginine in place of 0.1% urea and the penicillin was omitted. None of twelve rats infected with 10^9 CCU per 0.1 ml developed vesical calculi (Table 1). Stone formation is thus not a general property of all mycoplasma species.

Our results establish the ability of human T mycoplasmas to cause vesical calculi in male rats following bladder or renal inoculation. Stones were not inhibited by antibiotics, and were produced by acetone or heat killed T mycoplasmas so that their formation does not require viable organisms. The specific association of $MgNH_4PO_4.6H_2O$ stones with infection by urease-producing bacteria has long been appreciated[13]. This would suggest that the urease content of T mycoplasmas may be a factor in stone generation. But $MgNH_4PO_4.6H_2O$ stones also occur experimentally in the bladder of rats in the absence of urea-splitting organisms[14].

One of the unresolved aspects of stone formation is the site of nucleation and the subsequent retention of the stone nucleus within the urinary tract[15,16]. The property of T mycoplasma colonies to adsorb mammalian cells[17] may relate directly to this point. For example, T mycoplasmas may attach to epithelial cells in the urinary tract by specific receptors and serve as a stone nidus. As mycoplasmas seem to adsorb serum proteins to their surface[18], T mycoplasmas may also be able to adsorb urinary mucoprotein, the principal component of the organic matrix of stones[19]. Further, aggregation of the Tamm-Horsfall urinary mucoprotein can be caused by lowering the urea concentration[20]. Thus, the common presence of a T mycoplasma in the urinary tract, its capacity to attach to mammalian cells, and perhaps to adsorb proteins to its surface, and aggregate mucoprotein by breaking down urea, all suggest it may serve as a nucleus and part of the organic matrix of human urinary tract stones.

We thank Wallace A. Clyde for the T960 strain of mycoplasma, Herndon Douglas for technical assistance and L. Herring for performing the crystallographic analyses. The work was supported by grants from the National Institutes of Health.

Genetic Dissection of Active Electrogenesis in *Paramecium aurelia*

NEUROPHYSIOLOGISTS frequently use various drugs and toxins to interfere with specific membrane mechanisms. A genetic approach can achieve the same results. In taking this approach to the problem of excitation it is desirable to have an organism, like *Paramecium*, on which both formal genetic[1] and orthodox electrophysiological[2] studies can be made.

The behaviour of ciliated protozoa is under the direct control of the membrane. Thus, we have efficient methods of screening for membrane mutants which rely on their behavioural peculiarities[3-4]. Wild-type paramecia show "avoiding reactions" to various stimuli[5]. This is accomplished through a period of backward swimming in which the direction of ciliary beat is reversed. This behavioural reaction is correlated with membrane excitation. Mechanical, electrical and chemical stimuli can result in depolarisation of the membrane[6,7]. Suprathreshold depolarisation activates a regenerative increase in Ca conductance. The increase in internal Ca concentration through the Ca influx apparently activates the reversal of ciliary beat[8]. The system returns to normal through repolarisation and active ion transport.

The upstroke of the action potential is considered the result of a Hodgkin cycle, with Ca^{2+} instead of Na^+ carrying the action current in *Paramecium*[6,7]. Concepts such as Ca inactivation, K-delayed rectification, and ion pumping are also introduced to explain the relevant phenomena. Although the molecular mechanisms of these membrane functions in protozoa as in metazoa are still obscure, it is reasonable to think that only macromolecules, presumably membrane proteins, can carry out such complex functions. Genic mutations with corresponding loss of the normal gene products could therefore lead to malfunctions in various membrane processes, which in *Paramecium* are closely associated with the ciliary motion, and could eventually surface as behaviourally aberrant phenotypes.

Kung[3,4,9] and more recently Chang and Kung[10,11] have mutagenised populations of *P. aurelia* with N-methyl-N′-nitro-N-nitrosoguanidine and, by screening, have obtained

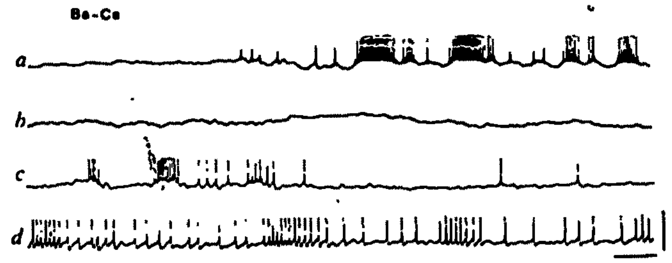

Fig. 1 Potential records of various strains 2–3 min after Ba solution entered the bath. *a*, Wild type; *b*, Pawn; *c*, Fast-2; and *d*, Paranoiac. Calibration: 5 s and 50 mV.

over 170 lines of mutants with various behavioural abnormalities indicating membrane malfunctions. Three unlinked genic mutants each representing a type were used here. These mutants were (1) "Pawns" (Stock d4–95, genotype *pwB pwB*), behaviourally characterised by the inability to reverse their ciliary beat even upon extreme stimulation. This behavioural deficiency was found to be correlated with the loss of proper membrane excitation[12]; (2) "Fast-2" (Stock d4–91, genotype *fna fna*) having an accelerated forward movement and an insensitivity specifically to Na stimulation; and (3) "Paranoiacs" (Stock d4–90, genotype *Pa Pa*) which show a form of violent over-reaction to Na$^+$ but not to other stimuli. The wild type Stock 51s (non-kappa bearing) of syngen 4 of *P. aurelia* was used as control.

Much of the literature on the behaviour of *Paramecium* describes the immediate reactions when cells from one solution are put into a second solution of different ionic composition[13,14]. The bulk of the electrophysiological work in *Paramecium* deals, however, with the evoked potential changes when the cells have been equilibrated for a few minutes to bath solutions of various ionic compositions[6,7]. To study the physiological correlates to chemotactic responses against various cations, we continuously monitored the membrane potential through various changes of ionic solutions.

The cell was first adapted in a K solution of 4 mM KOH, 1 mM CaCl$_2$, 1 mM citric acid and 1 mM Tris-HCl, *p*H 7.2. In this adaptation solution, membranes of wild type and all mutants were quiet and registered a resting potential of -20 to -30 mV.

To test the wild-type membrane reaction to Ba^{2+}, a Ba solution of 4 mM BaCl$_2$, 1 mM CaCl$_2$ and 1 mM Tris-HCl, *p*H 7.2, was let into the bath to replace the K solution. The resting potential gradually diminished to -5 to 0 mV in 3 to 5 min. At this level the membrane spontaneously discharged. Such repetitive firings of all-or-none action potentials are known to be correlated with quick backward jerks observed in the free-swimming animals when they encounter the Ba solution[2].

In reaction to Ba solution, both Fast-2 and Paranoiac mutants generated the Ba spikes typical of the wild type (Fig. 1*a*, *c* and *d*). Considering the variations encountered within the same strain, the frequencies of these spikes observed in different strains are not meaningful. There was, however, a complete absence of action potentials in the case of Pawns treated identically with the other strains. Even under conditions known to increase the spike frequency and duration in wild type, such as a solution with Ca^{2+} concentration reduced to 0.3 mM, Pawn membrane never fired (Fig. 1*b*). This result agrees with the finding of Kung and Eckert[12] that Pawn is not capable of proper electrogenesis due to an impairment of the molecular mechanism for the voltage-sensitive Ca conductance changes. It also agrees with the behavioural observations that all strains discussed avoid Ba except Pawns[3].

We discovered a distinct pattern of active electrogenesis correlated with the chemotactic avoiding reactions against Na$^+$ by the wild type. This pattern appeared in 15 to 25 s after an Na solution (4 mM NaCl, 1 mM CaCl$_3$ and 1 mM Tris-HCl, *p*H 7.2) began to flow into the bath in place of the K solution. No obvious change in the apparent resting level was observed, yet active depolarisations occurred. The rising phase of each episode began with a slow but sudden depolarisation rising from the resting level or rebounding from a slightly hyperpolarised level resulting from a previous episode. The rate of rise increased rapidly to that typical of the upstroke of action potentials. The spike peaked at about 20 mV from the resting level. The potential then oscillated for several hundred ms before returning to or slightly overshooting the resting level.

This gradually damped into patterns with lower spiking frequency, with spikes interspersed with spikeless depolarisations. Careful observation suggested that each spiked depolarisation episode was correlated with a sudden reversal of ciliary beat, and that in free swimming animals it most likely corresponded to the short avoiding reaction observed when the cell encountered Na$^+$. This behavioural correlate, and the fact that 10^{-7} to 10^{-5} g ml^{-1} of tetrodotoxin did not abolish the active electrogenesis, indicated that the action current was probably carried by Ca^{2+} although Na$^+$ may play an important part in events previous to the spikes.

Fewer but active depolarisations were observed when Pawns encountered the Na solution (Fig. 2*b*). Each depolarisation episode differed, however, from that of the wild type (Fig. 2*a*) by a clear lack of spikes. The plateau magnitude and duration of this depolarisation and the kinetics of repolarisation did not differ significantly from the wild-type pattern. This mutated form of active electrogenesis related to no observable behavioural response and apparently caused no ciliary reversal.

No sign of active electrogenesis was observed when Fast-2 first encountered the Na solution (Fig. 2*c*). There was not even the slow rise of resting level found in the other strains in reaction to the Na solution. After a long delay (more than 5 min), however, the membrane eventually drifted to -10 mV. At this time, trains of all-or-none action potentials were observed. This membrane also showed spike-like hyperpolarisations much more frequently than normal membrane.

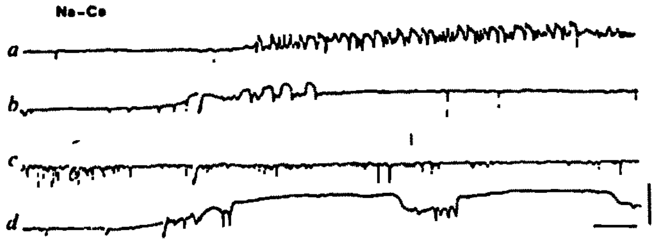

Fig. 2 Intracellular potential records during chemotaxis to Na$^+$. Na solution (without citrate) was let into the bath in place of the adaptation solution at the beginning of traces *a*, *b* and *d*; *c* begins 30 s after the Na solution starts to flow into the bath. Calibration: 5 s and 50 mV.

The membrane of Paranoiac reacted to the Na solution with a peculiar pattern (Fig. 2*d*). There were active depolarisations but they were often sustained at the plateau for up to 60 s. Two such resposes lasting around 20 s are shown in Fig. 2*d*. The kinetics of repolarisation is very different from that of wild type or Pawns. When the plateau phase of the depolarisation was shortened, the recovery kinetics closer to that of the wild type. As in wild type, there was also variation in the upstroke of the depolarisation. The prolonged action depolarisations coincided with the Paranoiac over-reaction to Na of this mutant. Details of the mutant electrical activities will be published elsewhere.

Mutations are usually deleterious, resulting in impairment of orderly biological processes. Thus, the mutant patterns of electrogenesis in the presence of Na^+ could be viewed as modifications of the wild type pattern with single point blockages (Fig. 3).

The depolarisation pattern of Pawns can be viewed as the wild type pattern with a block on the upstroke of the action potential. Current injections of various strengths and durations up to 2×10^{-9} A for 1 s (depolarising the membrane by 20 mV) during our experiments in Na solution evoked no spikes. The nature of the spikeless depolarisation pattern observed in Pawns in reaction to the appearance of Na^+ is obscure. It is apparently triggered by Na^+, never observed in the K-Ca or Ba-Ca solutions used and may relate to chemoreception of Na^+.

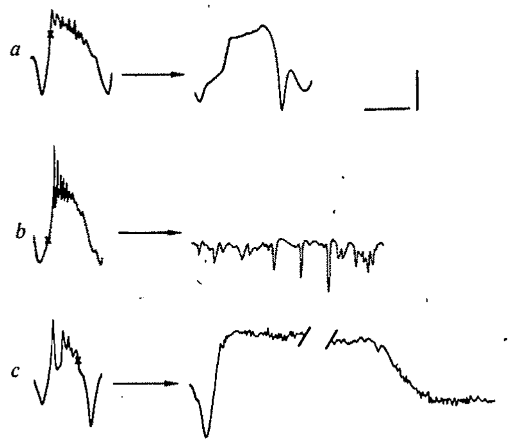

Fig. 3 A hypothesis showing that mutational blockages at various points of a normal depolarisation which occurs during Na chemotaxis can lead to different aberrant patterns. The three figures on the left are variations of the wild type patterns recorded in Fig. 2; the figures on the right are mutant patterns produced by blocks at different stages of a normal depolarisation. *a*, The spiking component is blocked by the *pw* gene leading to the Pawn pattern. *b*, Gene *fna* blocks the early depolarisation event and thus results in the Fast-2 pattern. *c*, Gene *Pa* blocks the proper repolarisation process and thus sustains and prolongs the depolarisation. Calibration: 1 s and 10 mV.

The pattern of Fast-2 in reaction to Na can be viewed as the result of a mutational blockage in the normal depolarisation process, located before the Pawn blockage. This results in a total loss of depolarisation correlating with the specific loss of chemotactic reactions against Na^+. Presence of Ba spikes, delayed action potentials in Na^+ as well as electrically evoked action potentials indicates that the Fast-2 membrane is excitable. The mutational blockage, therefore, does not extend to the component blocked by the Pawn gene.

The intriguing patterns of Paranoiac in the Na solution may be viewed as the result of a genetic block of the normal process of repolarisation. Because of the lack of a proper shut-off mechanism related to Na^+, the membrane potential stays near the peak of depolarisation for a greatly prolonged period and eventually drifts back to the resting level through a secondary repolarisation mechanism unaffected by this mutation.

As a description of the physiological abnormalities of various membrane mutants in *P. aurelia*, this study demonstrates the power of the genetic approach in systematically modifying a complicated biological phenomenon: the active electrogenesis during chemotactic reaction against Na^+. This approach may aid in the search for a molecular mechanism for excitation by correlating the mutant phenotypic expression at various levels of investigation and by identifying the gene products. This rationale of applying genetics to neurobiology was first stated by Benzer[15].

We thank Professor Roger Eckert for discussions and Mrs S. Y. Chang for assistance. The work was supported by grants from the US Public Health Service and National Science Foundation.

Regulation of Spawning Behaviour in the Female Goldfish

ALTHOUGH the role of hormones in the control of sexual behaviour in female mammals is well established[1], this is not the case with fish[2]. In spite of several reports that castration of female fish eliminates sexual behaviour[2], only two investigations have demonstrated successful steroid replacement therapy[3,4]. We report here, however, the induction of sexual behaviour in female goldfish (*Carassius auratus*) by injection of ovulated eggs into the ovarian lumen of individuals with vitellogenic ovaries, and also by administration of both eggs and oestrogen to individuals with regressed ovaries.

In goldfish, ovulation can be induced in several days by a change in water temperature from 12° to 20° C. At this 'summer' temperature, females ovulate once or several times within about a month, after which the ovaries regress. At ovulation, the eggs are released into an ovarian cavity which is continuous with the oviduct. Oviposition (release of eggs through the ovipore) occurs during a series of spawning acts. The female approaches and enters floating vegetation in a head-up position, the male following from below. Both turn on their sides and, as they break the water surface, the male presses against the female and appears to push her out of the water. Eggs and sperm are released this time and fertilisation occurs. This procedure may be repeated up to several hundred times during 1–3 h. Spawning behaviour of the female is seen only in the presence of male goldfish and green plants[5].

Encouraged by Yamazaki's[5] findings that (1) spawning behaviour was seen only in goldfish which had ovulated, and (2) hand-stripping of ovulated fish terminated this behaviour, we investigated the role of ovulated eggs. We found that when oviposition is prevented by a plastic and glass plug in the ovipore of an ovulated female, spawning behaviour is extended. Whereas spawning usually lasts less than 2 h, 'plugged' females perform the spawning act (without oviposition) throughout the day of ovulation and sometimes continue the following day.

To determine whether placement of eggs in the ovarian lumen would induce, rather than prolong, spawning, ovulated females were allowed to spawn with a male for 20 min to obtain individual normal spawning rates. The fish were then hand-stripped of all remaining ovulated eggs, placed with an actively courting male, and observed for 1 h to ensure that spawning had terminated. Then all were anaesthetised in MS222 (tricaine methanesulphonate, Sandoz) and given one of three treatments: (1) a handling control, (2) a plastic and glass oviduct plug fitted in the ovipore, and (3) an injection of the individual's own ovulated eggs through the ovipore, followed by an ovipore plug to prevent egg loss. In this last treatment, eggs were squeezed into a plastic cup and taken up in a 1 ml plastic syringe fitted with plastic tubing (PE 190). Eggs were injected into the ovarian lumen by inserting the tip of the plastic tube through the ovipore. It was important to prevent the eggs coming into contact with water, as this caused adhesion and hardening.

Within 10 min of treatment each female was placed with a sexually active male and behaviour recorded for 1 h. There was no difference between pretreatment spawning rates of the three groups, but injection of eggs stimulated spawning (Table 1).

Table 1 Effects of Injection of Ovulated Eggs into the Ovarian Lumen on Spawning Behaviour of Ovulated, Hand-stripped Goldfish

Group	N	Before treatment Spawning rate* No. spawning	Mean	Range	After treatment Induced spawning rate† No. spawning	Mean	Range
(1) Control	11	11	32	14–60	1	7	
(2) Oviduct plug	11	11	40	20–56	4	6.5	1–11
(3) Egg injected	11	11	34	9–60	11	28	7–57

* No. of spawning acts per 20 min.
† No. of spawning acts in the most active 20 min of the test hour.

Next, we sought a time after ovulation when egg injection did not induce spawning. Surprisingly, injection of ovulated eggs into females which had not ovulated for at least a month usually resulted in spawning within 2 h. Furthermore, physical substitutes for eggs (gelatine, petroleum jelly and ovipore plugs) sometimes induced spawning, but the response was much smaller than with egg injections, suggesting that chemical as well as mechanical stimuli may be involved.

Females kept at 20°–22° C for 4 months or longer invariably failed to respond to injected eggs. Their ovaries were small, resembling those of hypophysectomised fish, and probably represented the phenomenon of temperature regression found in *Gillichthys*[6]. The oocytes were in the first growth phase with little or no yolk.

We thought that the unresponsiveness of temperature-regressed fish may result from reduced oestrogen secretion. To test this, we investigated whether 17β-oestradiol would restore the spawning behaviour of these fish. Four groups of female fish were used. Group 1 (control) received four or five saline injections on alternate days before being injected with eggs on the test day. Group 2 received oestrogen but was not given egg injections. Group 3 fish were injected with oestrogen before receiving eggs. Group 4 (recently-ovulated control) received only egg injections on the test day.

Fish in groups 1, 2 and 3 had regressed ovaries. In each group, half the females were known to have ovulated soon after being warmed to 20° C several months earlier; the others had not ovulated in that period. Fish of group 4 had ovulated 3–9 d before the test day. 17β-Oestradiol was injected intraperitoneally as a saline suspension (0.6% NaCl, four drops Tween 80 per 100 ml) at a concentration of 2.5 μg μl^{-1} and a dose of 20 μg per g body weight on alternate days for 7 or 9 d. Control fish received either an equivalent volume of saline and Tween 80 (group 1) or no previous treatment (group 4). On the morning of the day after the final injection, females in groups 1, 3 and 4 were anaesthetised in MS222, injected with eggs (0.025 ml per g body weight) from an ovulated female, fitted with an ovipore plug, and placed in a 15 gallon test aquarium at 20° C. Group 2 was simply anaesthetised and left to recover in the test aquarium. An actively courting male was added to the aquarium after 30–50 min and the pairs were observed continuously for 3.5 h.

Table 2 Effect of 17β-Oestradiol on Spawning Behaviour of Temperature-regressed, Egg-injected Female Goldfish

Group ovaries	Treatment	N	No. spawning	Mean spawning acts per 3 h*
(1) Regressed	Saline and eggs	12	2	63
(2) Regressed	Oestradiol	6	0	0
(3) Regressed	Oestradiol and eggs	12	12	66
(4) Active	Eggs	7	7	94

* Based on responding individuals.

Of twelve control fish treated with saline and eggs, only two spawned (Table 2: group 1). The response was not measurably affected by whether the fish had ovulated since being held at 20° C (one of six spawned in each case). Oestradiol alone failed to induce spawning in the regressed females in group 2, again demonstrating the necessity of having eggs in the ovarian lumen. In contrast, spawning was observed in all regressed fish receiving oestradiol and eggs (group 3) and in all recently ovulated fish receiving only eggs (group 4). Our method for obtaining regressed female goldfish is, however, crude: some fish are not fully regressed and have ovaries in early stages of vitellogenesis. The two responding fish in group 1 were in this condition, suggesting that their spawning was due to endogenous steroids.

Yamazaki's[5] and our own observations suggest that under natural conditions female goldfish have an extended breeding season during which they may ovulate and spawn several times during a period of weeks. An important role of oestrogen seems to be to induce and maintain responsiveness to the stimulus of ovulated eggs; there is no indication whether oestrogen acts peripherally or centrally, or both. The fact that readiness to perform oviposition behaviour in response to male courtship is induced by egg injection up to a month after the last ovulation indicates that the female goldfish is in an endocrine state appropriate for breeding for an extended period, but that spawning is normally synchronised with ovulation by the stimulus of a large intra-ovarian mass of ovulated eggs, which acts as a fine control in the timing of sexual responsiveness.

It would be interesting to determine whether comparable mechanisms exist in other fish or in other egg laying lower vertebrates. The fact that oestrogen alone restores sexual receptivity of female guppies which have been both hypophysectomised and gonadectomised[4] suggests that in viviparous forms stimuli from the gonads or accessory structures may not be essential for the expression of sexual behaviour. In previous studies[2], the failure to induce sexual behaviour in female fish by oestrogen therapy may have been due to the absence of the requisite stimuli from internal sexual structures.

Evidence for the Two-state Model of Nematode Behaviour

A MODEL for the swimming and orientation of *Panagrellus silusiae* based on transitions between two behavioural states has been proposed[1]. The basis of this model is that in normal, unstimulated conditions the nematode follows a more or less linear path with the anterior and posterior ends of the animal sweeping through a minimal area. This is termed the 'normal' behavioural state. When stimulated by chemical or physical means, the animal enters the 'activated' state, making rapid changes in orientation with the ends of the animal sweeping through a maximal area. In the case of a gradient of an attractant, the animal remains in the activated state until it orientates to the gradient by sensing the maximum difference in intensity of the stimulus between the posterior and anterior sensory structures, at which point the animal returns to the normal behavioural state and migrates to the source of attractant. Laser microbeam studies indicated that the copulatory spicules of the free-living *P. silusiae* function as the posterior receptors for orientation to mating attraction in this species[1], and a sensory function has also been found for the spicules in other species[2].

Ward[3] proposed that chemotaxis of the free-living *Caenorhabditis elegans* is mediated by comparisons of stimuli by the anterior sensory receptors at successive lateral sweeps (klinotaxis). This mechanism requires some type of short-term memory system in nematodes, which has been demonstrated in *P. silusiae*[1].

The 'two-state' model was based on frame-by-frame analysis of video recordings of *P. silusiae* swimming in response to a range of chemical and physical stimuli, but the klinotaxis model[3] was based on examination of the tracks of normal and mutant nematodes in response to gradients of cyclic nucleotides, ions, amino acids and *p*H. Here we report further support for the two-state model based on analysis of tracks of *P. redivivus* males migrating in gradients of sexual attractant.

Tracks of individual males of *P. redivivus*, strain N, on 4% Czapek dox agar were recorded photographically (N. Croll, personal communication). The sources of mating attraction were blocks of 1.5% agar exposed to females for 24 h (ref. 4). Males were placed 2.5 cm from the source of attractant and tracks were recorded after 15 min. Analysis of the tracks involved measuring the linear distance travelled, the number of turns (changes in direction of tracks), loops (360° turns accomplished through forward motion only) and reversals (backward motion) made in the 15 min period (Table 1).

Table 1 Activities of Adult Males of Strain N *P. redivivus* in Unstimulated Conditions and in Response to Mating Attractant from Females of Strains C and N

Stimulus	Distance (cm)	Loops (No.)	Reversals (No.)	Turns (No.)
None	1.71±1.06	5.43±1.61	22.81±3.16	26.59±4.44
C females	2.13±0.19	16.59±3.31	34.42±3.96	128.79±14.47
N females	2.36±0.42	15.30±3.83	47.00±9.44	150.00±29.86

Figures are means during a 15 min test period.

Movement to attractant involves no significant increase in the distance travelled but does show significant increases in the number of loops, reversals and turns relative to those of males moving without attractant. This shows that the behavioural activities of males responding to sex attraction are different from the normal behaviour. The pattern of the tracks of males responding to sex attractant (Fig. 1*a*) is exactly what would be predicted by the two-state model.

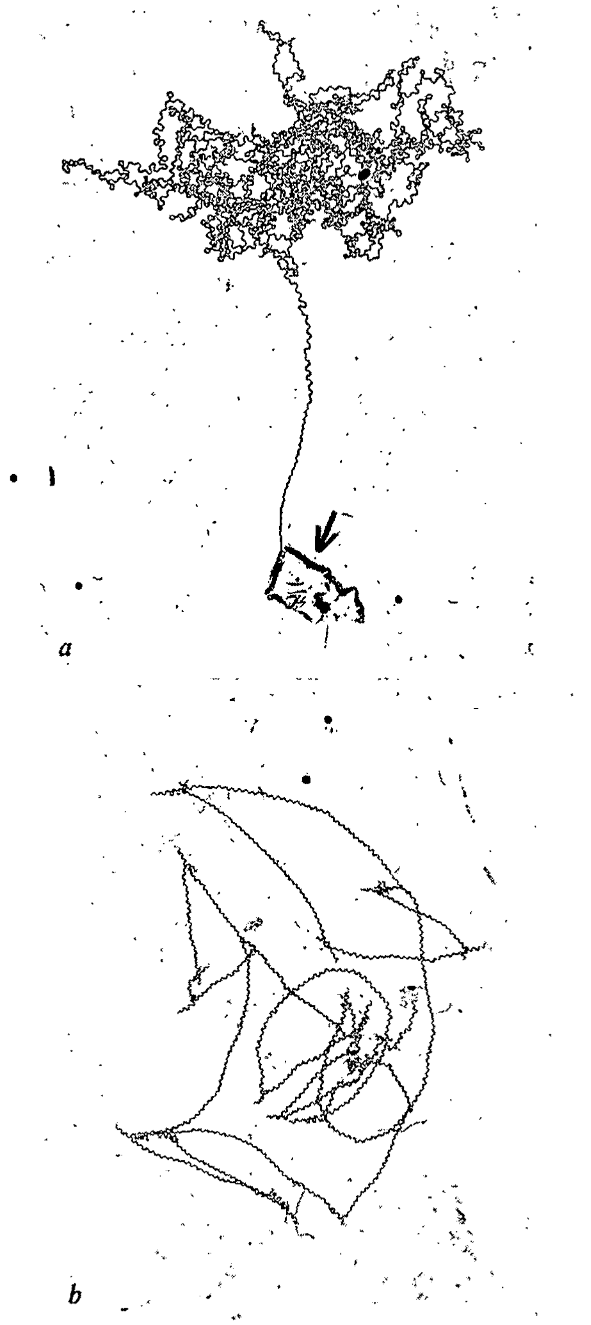

Fig. 1 Tracks of *P. redivivus* males, *a*, in response to sex attractant, *b*, unstimulated. The male responding to attractant (arrow) first undergoes a period of rapid changes in orientation (activated behaviour) and then migrates directly to the source of attractant.

Initially the males make rapid, constant changes in their orientation, with increased turning, looping and reversal; this is the period of activated behaviour. As the animal migrates towards the attractant the path is linear and direct; this is normal behaviour. Males moving when no attractant is present show a more or less linear pattern (Fig. 1*b*) broken by widely spaced changes in direction.

The two-state mechanism for sexual attraction does not preclude the functioning of klinotaxis in other classes of nematode chemotaxis. In *P. silusiae* sexual attraction is limited to one stage of the life cycle of one sex[4], but non-specific food attraction occurs at all stages of both sexes. This latter attraction does not involve the two-state mechanism.

Calcium Carbonate in Termite Mounds

The presence of appreciable quantities of calcium carbonate in termite mounds on non-calcareous soil has intrigued pedologists for many years. Milne[6], for example, found a termite mound with 7% calcium carbonate and estimated that it contained about 2 t of calcium carbonate excluding the hard limestone (53% $CaCO_3$) base of the mound. The soil below the base of a termite mound may also be calcareous. The soil underneath one termite mound in an area of non-calcareous soil was found to have a mean of 1.7% calcium carbonate to a depth of 6 m, or about 20 t of calcium carbonate[9].

The task of finding the primary methods of calcium carbonate accumulation has been hindered by the fact that termite mounds are complex systems involving biological and physical processes. Milne[6] and Pendleton[7] suggested that the most probable biological method was the collection of food by termites and formation of calcium carbonate from the mineralised residues. Other biological methods of calcium carbonate accumulation that have been advanced are as follows: (1) exchangeable calcium in soil collected incidentally by termites with their food[6]; (2) exchangeable calcium in soil collected purposely by termites requiring an alkaline environment[8]; (3) calcareous material collected from below the depth of soil said to be non-calcareous[3,7]; and (4) calcium-containing groundwater brought up by termites[2]. The physical methods proposed all involve evaporation of water containing calcium bicarbonate from a termite mound as the means of accumulating calcium carbonate, but they differ in the source and mode of entry of water into the mound. Thus Milne[6] suggested that water moves upward into the termite mound by capillary action. Den Doop[4] considered that the water evaporating from the mound was derived from surrounding land in the wet season. Boyer[2] too describes how water from perched water tables drains laterally and collects underneath mounds of *Macrotermes subhyalinus*. Finally, Hesse[5] found an association between calcareous *Macrotermes* mounds and poorly drained soil which led him to state that saturation of the base of a termite mound by groundwater was a prerequisite of calcium carbonate accumulation.

The early ideas on the mode of accumulation of calcium carbonate in termite mounds were considered by Pendleton[7] who said of some of them that they "seem too fantastic to repeat". He came to the conclusion that there was no known method by which termites or pedological processes could bring about the observed accumulation of calcium carbonate in termite mounds. There seems therefore to be a need for a different approach to the problem. A weakness of all proposals made hitherto is the long time that it would take to accumulate large amounts of calcium carbonate.

I have constructed a hypothesis that could account for more rapid accumulation of calcium carbonate in a termite mound.

The hypothesis (Fig. 1) is that calcium carbonate can accumulate in termite mounds by means of a two-stage process.

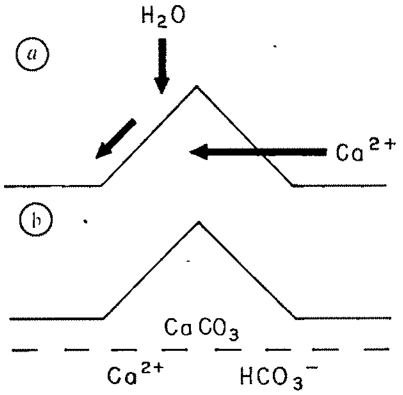

Fig. 1 Two stages in the accumulation of calcium carbonate in a termite mound. *a*, Elevation of the *p*H of the termite mound. This is brought about by termites carrying vegetation into a mound, aided by the fact that a mound sheds rainwater; *b*, precipitation of calcium carbonate as a result of contact between a termite mound of high *p*H and groundwater of low pH_c.

(1) Elevation of the *p*H status of the termite mound above that of the pH_c of the groundwater. An increase in the *p*H of a mound is brought about by termites importing vegetation which is decomposed to release exchangeable bases. Retention of exchangeable bases in the termite mound is facilitated by a low degree of leaching because a mound sheds water[9].

(2) Saturation of the base of the termite mound by groundwater containing calcium bicarbonate which precipitates as calcium carbonate according to the equation

$$Ca^{2+} + HCO^-_3 \longrightarrow CaCO_3 \downarrow + CO_2 \uparrow$$

The tendency for calcium carbonate to precipitate from irrigation water on contact with soil is a well known alkalinity hazard of irrigation schemes, and it has been found by Bower[1] to be related to a modified Langelier saturation index:

$$\text{Modified saturation index} = pH_s - pH_c$$

where pH_s is the *p*H value of the soil and pH_c is the theoretical *p*H value that the water would have if in equilibrium with calcium carbonate. Bower states that precipitation of calcium carbonate occurs if the index is positive. Moreover, the percentage of the applied bicarbonate that precipitated was found to be highly correlated with the value of the index.

This *p*H-dependent precipitation of calcium is related to the presence of bicarbonate and carbonate ions and does not occur with other common anions in groundwater, namely, chloride and sulphate. Formation of calcium carbonate in termite mounds in some regions and not in others may therefore, perhaps, be explained by differences in the anion composition of the groundwaters.

The rate of accumulation of calcium carbonate by means of the *p*H-bicarbonate process outlined here could be relatively fast in situations where groundwater of low pH_c flows past the base of a *Macrotermes* mound of high *p*H value. Consequently, if this hypothesis is correct, it will be unnecessary to assume that termite mounds have existed for the thousands of years that it would take to accumulate large amounts of calcium carbonate by evaporation of water.

book reviews

New horizons

Cosmology Now. Edited by Laurie John. Pp. 168. 8 plates. (BBC: London, November 1973.) £2.75.

THIS is, without doubt, the best introduction to modern cosmology available in book form. The list of contributors, each of whom provides one or two chapters, reads like a role of honour of the young cosmologists who have been at the forefront of the revolution in the subject over the past twenty years, with the addition of a couple of 'grand old men' such as Professor W. H. McCrea (whose outlook is certainly as youthful as that of any of the other contributors). For once, a claim made in the cover blurb (quoting Sir Bernard Lovell's introduction) can be taken at face value: this really is "the best description of the universe which can be given today".

But lest it seem that I am in the pay of the book's editor I should, perhaps, elaborate on the areas where it falls short of perfection, in the hope that some of these shortcomings might be rectified in a later edition. There is one glaring omission—in a book which is sure to attract the casual reader, and to whet his appetite for more cosmological fare, there is no bibliography or guide to further reading. Compared to this, the other points to which I take exception are only minor irritations, largely due, it would seem, to the editor's unfamiliarity with astronomy. Laurie John produced the radio series from which the book derives, and no doubt it is fitting that he should provide the introductory paragraphs which head each chapter. But surely among the wealth of cosmological talent contributing to the book someone could have checked these paragraphs, and the captions to the illustrations, for astronomical howlers?

Reference to quasars as "star like objects that may lie near the edge of the universe" is certainly misleading without qualification; far worse is the caption to Plate 8: "The star arrowed is a quasar"! It also seems a shame to introduce Martin Rees solely as "Plumian Professor of Astronomy" when the rest of his title ("and Experimental Philosophy") relates so appositely to the content of the book in general and his own contribution in particular. Apart from the quote from Sir Bernard Lovell the cover blurb is irritatingly out of key with the book, dragging in a reference to "the 'black hole', that ever-growing celestial maelstrom" which is likely to cause further distress to those astronomers already infuriated by the extravagant popularisations of black hole astronomy which have appeared recently; they can, however, safely ignore the words on the cover and be guided as to the true nature of the book by Professor Roger Penrose, who points out that no astronaut is likely to encounter a black hole by accident—"they would have to seek out a black hole deliberately if they wished to experience this 'ultimate trip' ". My final objection is purely a personal one—I have no liking for Professor John Taylor's homespun cosmological philosophy. But that may indicate a failing in me rather than in him.

Such a small catalogue of complaints shows, perhaps, how good the book is in general. As far as the detailed exposition of cosmological ideas is concerned there is little to say here except that all the contributions are readable and intelligible without any prior mathematical knowledge, and the few illustrations are equally clear and provide a valuable addition to the text. Quite apart from the 'introductory text' aspect of this volume, however, the contributions provide a valuable insight into the personalities of the contributors and the kind of bric-a-brac of odd bits of information which make it valuable in historical terms. I was particularly intrigued, for example, to discover from Dennis Sciama's contribution that Dicke and his colleagues were unaware of Gamow's earlier 'hot big bang' model of the Universe when they reintroduced the idea in 1965; I would have thought every astronomer remembered Gamow's work, if only because of his cunning choice of co-authors in writing the classic paper by Alpher, Bethe and Gamow—certainly I knew of this work in 1965, when much to my delight I discovered that paper as part of an undergraduate project. And certainly once discovered it is never forgotten.

Professor J. V. Narlikar also produces a memorable sentence: "Until the observational situation clarifies further it is premature to write off the steady state theory". That is particularly encouraging for those, like myself, who have a fondness for the steady state theory, and it does seem that the model has regained some ground since the dark days of the mid-1960s. But I must confess that while my gut reaction is still 'steady state, right or wrong' my head tells me that the evidence in favour of the hot big bang is very nearly overwhelming.

I also have a fondness for Mach's Principle, first propounded by Bishop Berkeley and today, it seems, rather more widely approved than steady state cosmologies. And when investigating the triumph of head over gut in the big bang–steady state dilemma, the future historian of science will no doubt be intrigued to learn from Sciama's contribution that he was persuaded, in 1966, of the great difficulties presented by trying to explain radio observations in steady state theory terms by "my student, Martin Rees". That same Martin Rees contributes to the book in his capacity now as Plumian Professor; an indication of just how much ground has been covered by essentially one generation of cosmologists.

So the book is well suited to the casual reader, to the historian of science, to specialist astronomers and to students. With an eye particularly to the needs of the latter, I hope that it may soon be available in paperback form at an even lower price, although it is certainly good value already.

JOHN GRIBBIN

Descriptive embryology

Embryology and Phylogeny in Annelids and Arthropods. By D. T. Anderson. Pp. xiv+495. (Pergamon: Oxford and New York, October 1973.) £8.

THE human brain, it would seem, is well adapted to the recognition and analysis of two-dimensional patterns, corresponding to retinal images, but is, as all teachers of anatomy know, far less adept at dealing with three-dimensional configurations. In embryonic development we are confronted with three-dimensional patterns changing in time; to produce a total image of such a development as a whole would be equivalent to thinking in four dimensions. To go even beyond this, in seeking to analyse a comparison between the embryonic developments of a whole series of animal species would in effect add even more dimensions to the problem. The daunting difficulty of this goes far to explain the recent unpopularity of studies in comparative descriptive embryology. Professor Anderson's book is to be welcomed as a bold and substantial inroad on this difficult field, comparable with Dawydoff's (1928) *Traité d'Embryologie Comparée des Invertebrés* or Johannsen and Butt's (1941) *Embryology of Insects and Myriapods.* The work is not merely a compilation from published sources, but incorporates much original work of Professor Anderson.

In seeking to draw phylogenetic conclusions from studies of embryology, the older authors looked for elements of Haeckelian "recapitulation", that is embryonic features resembling those of adults of more or less remote ancestral forms. Many features described by Anderson might be considered as recapitulatory in this sense; for example, the pre-mandibular somites and appendage rudiments of insect embryos, the transient coelomic sacs of numerous Arthropod embryos, the trilobite-like features of Crustacean nauplii and of the newly hatched *Limulus,* and the widely separated paired primordia of the insect labium. Most recent embryologists, Professor Anderson among them, minimise or ignore this line of evidence for ancestry.

Discounting recapitulation, he tries to draw phylogenetic conclusions from comparisons of overall developmental patterns in different taxa. In practice, of course, the limitations of humanity oblige him to concentrate attention on certain features abstracted from the total process; cleavage patterns, formation of germ layers, somite differentiation, are discussed in particular detail. Much stress is laid on 'fate maps' in relation to early embryonic stages. In this connection no distinction is made between 'mosaic' types of development, as in typical spiral cleavage of Annelida, where the future development of every cell is fixed from the beginning of cleavage, and 'regulation' types, known, for example, in many insects, where for a considerable time pieces detached from the embryo can be made good from the rest of it. The book gives well illustrated accounts of typical developmental patterns of all the major groups of Annelida and Arthropoda, but several phylogenetically interesting minor ones, such as the Echiuroidea (whose true position is probably in Annelida), the Tardigrada and Pentastomida, Myzostomida and Pycnogonida, for which embryological information is available, are omitted altogether from consideration.

The phylogenetic conclusions drawn by Professor Anderson coincide almost exactly with those expressed in a recent paper by Dr S. M. Manton "Arthropod Phylogeny—A Modern Synthesis" (*J. Zool., Lond.,* **171**, 111; 1973), to whom Anderson pays handsome tribute and dedicates his book. Dr Manton in turn frequently cites Anderson in support of her own, more dogmatically expressed views. A central conclusion of both authors is thus expressed by Manton: "It used to be supposed that the Arthropoda were monophyletic . . . now the polyphyletic nature of the group is inescapable, as is the acceptance of parallel evolution of roughly similar structures, for instance, compound eyes and biting jaws, in unrelated groups, such as insects and crabs". Dr Manton splits the Arthropoda into three groups, Uniramia (Onychophora, Myriapoda, Hexapoda), Crustacea and Chelicerata, which she treats as independent phyla; Anderson goes even further in questioning whether these three groups could even have had a common ancestor within Annelida. Dr Manton consigns the Trilobita to a kind of limbo outside her system, remarking also that "We can do no fossil embryology". If embryology is restricted to development within the egg, this may be true, but Anderson devotes a good deal of space to post-hatching stages in Polychaeta and Crustacea, and the palaeontologists have traced developmental stages in Trilobita back to a stage apparently comparable with a nauplius. The "modern synthesis" completely ignores evidence from recent protein studies, for example, of lactic dehydrogenases and similar enzymes, or from moulting hormones and other such substances.

It seems likely to me that future evidence will offer little support to the phylogenetic ideas of either author; Professor Anderson's book will, however, retain its value for embryologists, on account of the good and detailed accounts it provides of the earlier development of such a large and important group of animals, as well as for the excellent, full and up to date bibliographies which are appended to each of his chapters. If Dr Manton's phylogenetic theories are eventually proved wrong, this will not detract from the value of her earlier work on the movements and coordination of arthropod appendages, and her latest paper should at least act as an intellectual challenge to those who disagree with her.

R. A. CROWSON

Salomon's house

Science and Politics. By Jean-Jacques Salomon. Translated from the French by Noel Lindsay. Pp. xxii+277. (Macmillan: London and Basingstoke, July 1973.) £5.50.

THE science policy concerns of the 1960s are here paraded in full academic robes. The author was a Professor of Philosophy in Paris before he became head of the Science Policy Division of the Organisation for Economic Cooperation and Development, and his approach is that of a scholar: he gives no quick tips on how to provide the manpower, organise the research institutes or run an international project, but he is well read and his views are always interesting and worth considering.

Tackling his subject historically, he sees science policy as "the child of war", the military model being the ideal one for the mobilisation of science. When he discusses policy for science, he never tires of denying that the rationality of science somehow rubs off on scientific affairs, including technological forecasting. For readers in England he need not have repeated the point so often—the danger of a take-over by quantitative methods has never been great here, partly perhaps because of the healthy innumeracy of our decision-makers. Alvin Weinberg's criteria for scientific choice and the associated debate in *Minerva* get the space they deserve on account of their intellectual interest as well as the criticism they deserve for being "non-operational".

On the matter of science in policy, Salomon rejects the notion of an apolitical elite and insists, with R. Gilpin, that it is impossible for scientists to free themselves from values and non-technical assumptions. He introduces the term "technonature" to denote the borderland between science and government, between knowledge and power; it is "the inevitable meeting ground between the ideology and the scienticity of science" and it "brutally teaches scientists that informing political decision is not the same thing as forming it".

There is an interesting historical inaccuracy regarding the author's eponymic house. In Salomon's house as conceived by Francis Bacon in *New Atlantis,* the last of the nine categories of workers, the Interpreters of Nature, "raise the former discoveries by experiments into greater observations, axioms and aphorisms". J.-J. Salomon says their function is "turning experiment into action" (page 8). Trivial in itself, the shift from axioms to action is indicative of one of his leading ideas: that one can "no longer" separate pure from applied research, theory from practice. But when in history was there a time when science was "as innocent and pure as on the first day"? Is this anything more than another Adam-and-Eve myth? Galileo, it should be remembered, made money by selling a "military compass".

Salomon seems to suggest that science lost its innocence around the time of the Second World War—as though the birthright of the Mertonian norms (disinterestedness and so on) was then sold for a mess of pottage. This view is more convincing as a description of ontogeny than of phylogeny; it applies quite clearly to individual scientists such as Oppenheimer but much less clearly to science as a whole. Salomon even implies (page 183) that competition for recognition has become intense only since the 1920s. I suspect he misattributes the historical transformation: it is not so much the character of science which has changed as the writing about science which has become more sophisticated and realistic.

He is not critical enough of the discovery push type of thinking which sees technological innovation as the result of pure research. Historians—even non-Marxist ones—have realised that it is at least as illuminating to analyse the technological roots of science as the scientific roots of technology, and work on modern industrial innovation indicates that today, too, need pull is more important than discovery push and that the inputs from science into technology are in fact rather tenuous.

By the time a book appears in a second language, three years after its original publication, it should be free of historical howlers such as the one about "the steam engine, of which Watt had the first idea as early as 1765" (page 27). Readers used to the down-to-earth directness of the best English writings on the subject may find that too many of the Franco-English sentences need rereading before they yield a meaning.

F. R. JEVONS

Making the best of it

Optimum Structures. By W. S. Hemp. Pp. xii+123. (Clarendon: Oxford; Oxford University: London, May 1973.) £7.50 boards; £3.50 paper covers.

IN recent years a great deal of attention has been focused on optimal or optimum structures. Such systems have their components so arranged as to minimise internal forces and so dimensioned as to maintain uniform stresses. Originally this field of study proved to be of special interest to aircraft designers, but recently civil and structural engineers have also turned their attention to it. The basic principle of optimisation applies to all classes of structures, and the recent trend towards improved design of structures of minimum weight obtained at a minimum cost gathers momentum.

To achieve these aims a detailed knowledge of various factors and a clear picture of their mutual interdependence are required. Optimisation can produce the desired result and it can be described as a procedure used by the designer to decide on the one specific solution in a defined set of possible alternatives that will best satisfy a selected criterion. In the past the optimisation of structures has required lengthy and time-consuming calculations. The advent of digital computers is changing this, enabling the designer to compare many solutions in his search for the optimum structure. At the same time the interest grows in the fundamental philosophy regarding optimum structures.

Although there are already several papers published on this topic, Professor Hemp's book is unique, not only because it deals at great length with the basic principles of the analysis of optimum structures, but also because it incorporates a great deal of fundamental and highly original work of the author. Whereas most of the published articles deal with numerical methods, this book is mainly concerned with the derivation of the general principles of optimum structures using linear programming and the calculus of variations. It covers the treatment of pin-jointed frameworks, beams, circular sandwich plates, Michell's structural continua and plates loaded in their planes. Optimisation of structures can very easily become highly sophisticated and extremely difficult depending on the number of constraints or independent parameters considered in the analysis.

Although the treatment by nature is highly mathematical, the author has succeeded in producing a lucid exposition of the up-to-date methods of determining structures of least volume of material. He pays special attention to the use of Lagrangian multipliers. This is a book which many research workers and some designers will find extremely valuable in their search for the ideal structural form.

Z. S. MAKOWSKI

Currents in insulators

The Theory of Electrical Conduction and Breakdown in Solid Dielectrics. By J. J. O'Dwyer. (Monographs on the Physics and Chemistry of Materials.) Pp. ix+317. (Clarendon: Oxford; Oxford University: London, September 1973.) £10.

ONE might think that the subject of 'currents in insulators' was a contradiction in terms. This is not so: insulators have a wide forbidden band and hence often block the transport of current. But while it takes effort to introduce carriers into the conduction band, once they are there they run down potential slopes in the conventional way unless arrested by imperfections. Because of the difficulties of experimental study, the theory of charge transport in dielectrics is not so advanced as in semiconductors and metals. Injection of charge into thin-film insulators is, however, now seen to be potentially useful and this should raise the level of research performed.

The other technologically relevant field is the one treated in this book: when insulators are stressed to a very high field (over 10^8 V m^{-1}), new phenomena occur which turn the material into a good conductor, though perhaps only over a limited part of the area exposed to stress. This part then carries an increasing current until the material overheats and is destroyed. In high-voltage technology, these effects must be minimised where possible. For this, one must understand the conduction phenomena occurring at the onset of breakdown. The object of this book is to lay out, in a concise manner, the various pieces of theory and research concerning conduction in insulators which aid this understanding and then to build on these concepts a picture of the complex events leading to the final catastrophic breakdown.

The author has, on the whole, achieved these limited aims with a commendable economy of space. After a useful initial survey chapter, which sets the scene well, the reader is led, with little deviation, through the several types of conduction possible in insulators. The research results of many workers are quoted for cases in which it is advisable to show how a particular mathematical model is embodied in real life. So far, so good; however, the author is a specialist in the field of breakdown phenomena (this book is actually a greatly broadened form of a 1964 book outlining his own theory of breakdown). Perhaps because of this, he seems to lean over backwards to be impartial and, as a result, withholds any overt judgments on the relative merits of the experiments and theories described. Not only does he seem to be saying "now judge for yourself", but one is also left with the erroneous impression that every model ever devised for conduction in insulators is equally true and common, even though some do, in fact, conflict. It is a pity that the benefits of a highly informed point of view were so clearly withheld.

There is thus little to disagree with in this book. It is a good, dispassionate record of published fact. A few omissions can, however, be sensed by scanning the author and subject indexes; there is no entry for 'photoinjection' or 'filamentary conduction', although both loom large in charge transport through thin-film insulators—a field which one would expect to be covered in a book of the aims stated. Neither are the investigations of Berglund, Powell or Nicollian on various types of injection into silicon dioxide films, or the work of Dearnaley or Harrop on filamentary and a.c. conduction phenomena, given any mention. In general, the book thus has a bias towards 'bulk' experiments and places little reliance on thin films as media for elucidating transport phenomena—an unfortunate blind spot, since Lynch has recently built on such work to predict successfully the breakdown strength of silicon dioxide.

With this exception, it must be said that for a research student or working scientist who wishes to be quickly and smoothly introduced to or updated with respect to the concepts of transport in insulators (ionic as well as electronic), it will be well worth his while to have this book on his shelf. A lot of effort has been expended in whittling down the arguments to their core and selecting the best experimental examples for the reader's inspection. If the reader then has to go on a bit further in order to make his own value judgments, he will still have saved himself a lot of time in the library. A. G. HOLMES-SIEDLE

Fermi surfaces

The Fermi Surface: Its Concept, Determination, and Use in the Physics of Metals. By A. P. Cracknell and K. C. Wong. Pp. xii+565. (Clarendon: Oxford; Oxford University: London, August 1973.) £15.

IN his original work in 1926 Fermi introduced the thermodynamic potential, or degeneracy temperature—what we now call Fermi level—of a gas of electrons. Though he was well aware that these ideas were relevant to electrons in metals, he could hardly have foreseen what central role this concept would assume in solid-state physics and particularly in the theory of metals. As the preface to this book reminds us, Professor Mackintosh thinks that the most appropriate definition of a metal is "a solid with a Fermi surface", the surface being the locus of points in momentum space at which the one-electron energy is equal to the Fermi level. This quantum concept, in conjunction with the consequences of crystal periodicity, provides the foundation on which the properties of metals can best be discussed. The beautiful, and sometimes bizarre, shapes of these surfaces (the monster, the coronet, the super-egg . . .) are natural examples of abstract art, almost reflecting unconscious archetypal models.

The work which has led to the determination of these surfaces is among the most ingenious, elegant and fascinating in modern physics and this book aims at giving a complete authoritative account of all its aspects. It is a combination of an introductory treatise and an extended review article. The first two chapters give those parts of band theory which are necessary for a proper understanding of both theoretical and experimental methods. Chapter 3 describes the experimental methods, then two chapters, bringing up to date the well known review articles by one of the authors, describe the Fermi surfaces of metallic elements. Chapter 6 describes in an elementary way the effect on Fermi surfaces of electron interactions, and the work ends with an admittedly perfunctory treatment of alloys.

Probably the most striking characteristic of this exposition is its extreme clarity. The treatment of even difficult points flows effortlessly and should be well within the grasp of graduates who know the fundamentals of solid-state physics and of quantum theory (old style—the Dirac notation is not used). Of course the task of giving a simplified treatment which is not partly misleading is an impossible one, but we come near to achieving it here, and many teachers will get valuable hints for their lectures. By and large the choice of material appears very sensible; all the necessary definitions and explanations are given (or almost all: for instance the definition of Clebsch-Gordan coefficients seems to be missing); the usual "it can be proved that" is always coupled to an appropriate reference. Some sections are perhaps unduly discursive and some elementary items are included which could have been assumed to form part of the background, for example, Einstein's and Debye's theories of lattice specific heats. A notable omission is any reference to liquid metals. At least the extent of blurring of the Fermi surface might have been indicated, and a reference to Professor March's monograph given.

The book is thus a very useful introduction to the subject, but its main value is as a collection of results of work on Fermi surfaces complete up to 1971 with some later references. The total number of references is almost one thousand and they all fit neatly into their appropriate slot. I have failed to find any aspect of any importance which is not adequately covered. The authors will receive the heartfelt gratitude of all "Fermiologists" and it is safe to say that this will remain the standard treatise on Fermi surfaces for a long time, even if some parts should become surpassed. It is a pity that the price should be so high, even taking into account today's wild inflation, and the quality of reproduction of the illustrations is not outstanding.

L. PINCHERLE

Gas theory

Mathematical Theory of Transport Processes in Gases. By J. G. Ferziger and H. G. Kaper. Pp. xiii+579. (North-Holland: Amsterdam and London, 1972.) Dfl. 120; $35.25.

THE year 1972 was the hundredth anniversary of the publication of the Boltzmann equation—apparently an auspicious year for the publication of a book on the kinetic theory of gases as based on this famous equation. This theory gives a complete prescription for calculating transport properties of dilute gases from knowledge of the intermolecular forces. As such, it is one of the most elegant and highly-developed physical theories available. But any book published in 1972 must face a severe test—comparison with two well known monographs, *The Mathematical Theory of Non-Uniform Gases* by Chapman and Cowling, now in its third edition (1970), and *Molecular Theory of Gases and Liquids* by Hirschfelder, Curtiss and Bird, in its second printing (1964). These are rightly regarded as classics, and have set a standard by which all other books in the field are measured. Ferziger and Kaper have attempted the difficult task of combining the best features of both of these works in a textbook for graduate study. Let me quote their own words for the reasons for the attempt. Chapman and Cowling ". . . is rather difficult as a text and does not emphasise the calculation of transport properties sufficiently. . . . Hirschfelder, Curtiss and Bird, while very good in discussing the calculation of transport properties, compresses the theory far more than desirable".

In my opinion the authors have succeeded admirably in their aim. There is no doubt that a real need exists for such a book, as evidenced by a prevailing opinion to the effect that ". . . reading Chapman and Cowling is like chewing on broken glass; reading Hirschfelder, Curtiss, and Bird is like punching a feather pillow". I wish a book like this had existed when I first started to try to understand kinetic theory.

This book covers much the same ground as Chapman and Cowling, but with more emphasis on intermolecular forces and the computation of transport coefficients. There are also excursions beyond the range of the Boltzmann equation to include modern work on dense gas theory and some discussion of rarefied gas dynamics. A book like this cannot hope to be complete, and in some areas will become out of date very quickly. One can see some signs of this already happening, but I do not feel that this detracts appreciably from the book's value. The discussion of fundamentals and mathematical developments is so well done as to be of almost permanent value, and the treatments of the more rapidly changing areas will enable the reader to proceed for himself into the research literature.

Finally, it is interesting to note that the book developed from a course intended for aeronautical, mechanical and chemical engineers. It should be of equal value to physicists and chemists, and even to biologists interested in phenomena describable by Boltzmann-type equations. I predict that it will be a standard text for some time to come. E. A. MASON

Classified Advertisements

CONDITIONS. All advertisements will only be accepted on the condition that the advertiser warrants that the advertisements do not in any way contravene the provisions of the Trade Descriptions Act 1968 and the Race Relations Act 1968. The Publisher also reserves the right to refuse, amend, withdraw or otherwise deal with all advertisements submitted to him at his absolute discretion and without explanation. All advertisements must comply with the British Code of Advertising Practice.

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes.

Semi-displayed £3.60 per 10 mm. Minimum £7.20, each additional 2 mm 72p. Full page £230.00. Half page across £125.00. 30p is charged for the redirection of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, London, WC2A 2ED. Telephone: 01-242 6264. Telegrams: Textualist, London, W.C.2.

APPOINTMENTS VACANT

UNIVERSITY OF THE ORANGE FREE STATE

C.S.I.R. FLAVONOID RESEARCH UNIT

RESEARCH ASSISTANTSHIP

Applications are invited for the above vacancy in the Department of Organic Chemistry tenable over a period of up to 3 years. The work involves postgraduate research in all branches of flavonoid and tannin chemistry leading to M.Sc. or Ph.D. degrees, according to initial qualification. Preference will be given to candidates for the Ph.D. degree. The position should be assumed as soon as possible after January 1, 1974.

Minimum initial salary with M.Sc. qualification: R3,000; B.Sc.(Hons.) R2,500.

Applications, giving details of academic record and curriculum vitae should be posted to Professor D. G. Roux, Department of Chemistry, University of the Orange Free State, P.O. Box 339, Bloemfontein, South Africa. (31)

ETON COLLEGE

SENIOR BIOLOGIST OR BIOCHEMIST

A Biologist with research or teaching experience is required from September 1974 as Head of the Biology Department. The Biology Department is well-staffed and attracts many able pupils: it has modern and well-equipped laboratories and incorporates a famous museum of natural history.

Apply, sending curriculum vitae and the names of two referees, to the Head Master, Eton College, Windsor, Berkshire.

(10)

UNIVERSITY OF ST. ANDREWS

DEPARTMENT OF PHYSICS

Applications are invited for appointment to the post of SCIENTIFIC OFFICER. The successful applicant will assist with work on electron scattering processes in semiconductors and metals at very low temperatures using a dilution refrigerator and SQUIDS (Superconducting Quantum Interference Devices). The appointment, which is supported by S.R.C., will be for a period of 20 months in the first instance, beginning as soon after January 1, 1974, as possible. The starting salary will be £1,764.

Applications, with the names of two referees, should be sent to Dr. D. M. Finlayson, Department of Physics, The University, St. Andrews, Fife, not later than January 15, 1974. (22)

Nicholas

Pharmaceuticals, Toiletries and Hospital Supplies

Biometrician/ Statistician

Department of Biology – Nicholas Research Institute

Applications are invited for the post of Biometrician who will be responsible for the design and analysis of all experimental work in the Department; this comprises pharmacology, microbiology, biochemistry and toxicology. Adequate computing facilities are available.

Applicants should be either graduates in Statistics or Mathematics/Statistics or Associates of the Institute of Statisticians.

Previous experience is preferable though not essential. Salary will be in the range £1,800 to £3,000 per annum and will depend on qualifications and experience.

The Company offers a wide range of fringe benefits, as would be expected from a growing international group.

Applications to: A. J. Strathdee, Personnel Officer, Nicholas Research Institute, 225 Bath Road, Slough, Bucks., SL1 4AU.

(76)

HARWELL

Computer Systems

We are looking for graduates with relevant postgraduate experience for appointments in our Computer Sciences and Systems Division in the fields of:

Real time systems
Multiprocessor systems
Information retrieval
Language development
Computer networks

Our research facilities include PDP 11-20, PDP 11-45 and Modular I computers linked to the central Harwell computer, an IBM 370/165. The appointments either to permanent posts, or Fellowships tenable for three years, carry a salary or stipend in the region of £2000–£3500 p.a. depending upon ability and experience. This range could be extended for a candidate with very extensive software experience. Younger candidates with limited software experience but with a strong interest and aptitude would receive appropriate training.

For further details and application forms please write to:
Appointments Section 'A', A.E.R.E., Harwell, Didcot, Berks.

(75)

Imperial
Chemical
Industries
Limited

Industrial Hygiene
Research Laboratories

Metabolic Research

The Laboratories provide central advisory and experimental toxicological services to the Company. There are vacancies for the following staff:

Two Biochemistry graduates with good Honours degrees are required to assist the head of the Unit in initiating studies on the intestinal absorption mechanisms of foreign compounds.

One Biochemistry/Chemistry graduate with a good Honours degree and relevant postgraduate experience is needed to investigate the metabolic fate of industrial compounds. Working familiarity with mass spectrometry would be advantageous.

A person with MI Biol in Biochemistry or Pharmacology or HNC (Applied Biology) and relevant experience is required to join a small team concerned with metabolic studies on pesticides.

Applications and enquiries should be addressed to:

Miss A Waring
Personnel Officer
Imperial Chemical Industries Ltd
Industrial Hygiene Research Laboratories
Alderley Park, Nr. Macclesfield
Cheshire SK10 4TJ
Tel: Alderley Edge 2711 ext 156

(56)

MICROBIOLOGICAL RESEARCH ESTABLISHMENT

PORTON DOWN

MANAGER, EXPERIMENTAL ANIMAL FACILITIES

£2,615 to £3,640

. . . to be responsible for all aspects of the management of the Experimental Animal Wing at M.R.E., including the supervision of twenty-five staff. This will involve close liaison with the scientific staff on the problems relating to the use of experimental animals. The successful candidate will be expected to make an important contribution to the introduction and development of new facilities of advanced design.

Candidates must have considerable experience of animal husbandry covering a wide range of animal species. They should normally have a degree, H.N.C., or equivalent in an appropriate subject, but candidates who do not possess these qualifications may be considered if they can show unusually wide experience in the management of experimental animal facilities.

Starting salary will be within the quoted scale. There is a non-contributory pension scheme.

For further details and an application form (to be returned by January 25, 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants; or telephone Basingstoke 29222, ext. 500, or London 01-839 1992 (24-hour answering service), quoting S/8495. (13)

HOUGHTON POULTRY RESEARCH STATION

Applications are invited for the post of

SENIOR VETERINARY RESEARCH OFFICER
OR
PRINCIPAL VETERINARY RESEARCH OFFICER

Applications are invited for a virologist with veterinary qualifications to be responsible for the study of avian respiratory viruses. The appointment will be made within either the Senior Veterinary Research Officer scale (£3,095 by 7 to £3,742) or the Principal Veterinary Research Officer scale (£3,963 by 6 to £5,202) depending upon qualifications and experience.

F.S.S.U. superannuation, membership of which attracts a non-pensionable allowance of 4¼ per cent of salary.

Further particulars and application forms available from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon PE17 2DA. Closing date for applications February 11, 1974. (14)

Upjohn *medicine . . . designed for health . . . produced with care*

Upjohn's Research Success could be your Career Opportunity

The success of Upjohn's research scientists in generating new products requires significant expansion of the Medical Division of Upjohn Limited. We wish to engage three people, either graduates or with suitable qualifications in pharmacy or one of the biological sciences, for posts in the following areas:—

MEDICAL INFORMATION

The responsibilities of this post will include handling medical and pharmaceutical enquiries from doctors and pharmacists and the provision of technical support for the Company's medical representatives. The successful applicant would also play a major part in the setting up and maintenance of a suitable information and retrieval system.

HEALTH REGISTRATION

The successful applicant will assist in the preparation of submissions for the medical and veterinary Safety Committees concerning new drugs entering trials or approaching marketing. Support will also be required in international programmes co-ordinated in the U.S.A. A sound awareness of the scientific and legal aspects of new drug development will be encouraged by liaison with the company's technical experts.

CLINICAL TRIAL LIAISON

The principal activity will be generation, collation and analysis of scientific data concerning clinical trials of potential new products. Supervision of trial supplies and some involvement with the setting up of clinical studies will also be included and a basic knowledge of statistics would be an advantage.

All three positions will be based in Upjohn Limited's modern head office building in Crawley, Sussex. The companys' benefit and salary programmes reflect its forward-looking attitude.

If you are interested, please write for an application form to:—

U.115 (73) The Personnel Manager, UPJOHN LIMITED, FLEMING WAY, CRAWLEY, SUSSEX RH10 2NJ

The University of Leeds

DEPARTMENT OF METALLURGY

Applications are invited for a POST-DOCTORAL RESEARCH FELLOWSHIP tenable for one year in the first instance. Salary not less than £1,929 per annum.

The successful candidate will be expected to work on repassivation studies on titanium and aluminium alloys under Dr. J. Scully. Applicants should have relevant research experience and a good basic knowledge of electrochemistry and corrosion.

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 36/4/D). Closing date January 31, 1974. (23)

UNIVERSITY OF GLASGOW

LECTURESHIP IN GENETICS

Applications are invited for a Lectureship in the Department of Genetics. The salary will be within the range £1,929 to £3,048 per annum of the Lecturers' scale of £1,929 to £4,548 per annum, placement will be according to qualifications and experience. F.S.S.U.

The person appointed will be expected to undertake such duties as are assigned to him by the Professor of Genetics, and will be expected to carry out appropriate research. There is a strong preference for applicants with research interests in developmental genetics, and experience in electron microscopy. However, applicants with experience in developmental or cell biology will be considered.

Applications (six copies) should be lodged, not later than February 1, 1974, with the undersigned, from whom further particulars may be obtained.

In reply please quote Ref. No. 3394M.

ROBT. T. HUTCHESON,
Secretary of the University Court.
(39)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY

TECHNICIANS

Applications are invited for the following posts:

(A) Technician to assist with the organisation and preparation of materials for classes in Cell Biology and Elementary Botany, and to carry out preparative work for physiological research. To commence March 1, 1974. Quote Ref. RV/N/80631(A).

(B) Technician to provide similar assistance in Marine and Freshwater Botany and Elementary Botany and to carry out field work and laboratory culture preparation. Driving licence preferred. To commence as soon as possible. Quote Ref. RV/N/80631(B).

Candidates for either post must possess O.N.C., City and Guilds or equivalent, and should preferably have relevant experience. Salary on the scale £1,524 to £1,794 according to qualifications and experience.

Application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. (63)

UNIVERSITY OF ALBERTA

Applications for GRADUATE STUDIES IN PHARMACOLOGY for the degrees of M.Sc. and Ph.D. are invited from students with a background in Biochemistry, Pharmacy, Biology, Chemistry or Medicine. Opportunities exist in Biochemical Pharmacology, Neuropharmacology and Smooth Muscle Pharmacology. Successful applicants may be eligible for financial assistance.

For further information write to: Dr J. S. Charnock, Chairman, Department of Pharmacology, University of Alberta, Edmonton, Alberta, Canada, T6G 2H7. (X3)

UNIVERSITY OF OXFORD. LECTURESHIP IN ORGANIC CHEMISTRY. Applications are invited for a University Lectureship in the Dyson Perrins Laboratory, to be held in conjunction with the Fellowship at Wadham College advertised below. Salary in range £1,929 to £4,863 (depending upon age), plus F.S.S.U.—Further particulars from the Administrator, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, to whom 6 copies of typed applications (only 1 from overseas candidates) should be sent no later than February 4.

WADHAM COLLEGE. OFFICIAL FELLOWSHIP IN ORGANIC CHEMISTRY. The College proposes to elect an Official Fellow in Organic Chemistry from October 1, 1974. Both men and women are eligible. The post is to be held in conjunction with the University Lectureship in the Dyson Perrins Laboratory advertised above.—Applications, giving personal details and a brief statement of academic record, should be sent not later than February 4, 1974, to the Warden, from whom further particulars, including the stipend and teaching duties, may be obtained. (6)

AHMADU BELLO UNIVERSITY

NIGERIA

Applications are invited for the following posts in the Institute for Agricultural Research/Faculty of Agriculture:

DEPARTMENT OF AGRICULTURAL ENGINEERING—PROFESSOR OF AGRICULTURAL ENGINEERING. Candidates should have a good honours degree in agricultural engineering, including a combination of basic engineering and agricultural science. A higher degree or postgraduate experience is essential. Administrative ability is required to provide leadership in teaching and research. It is essential that candidates have had experience in research requiring the application of the science and art of engineering to problems in agriculture. Academic experience in a university department would be an advantage. Some industrial experience would be advantageous. Appointee will be responsible for the organisation of the Department of Agricultural Engineering within the Faculty for teaching and within the Institute for research. Research emphasis is on the improvement of mechanisation on small farmer systems, including oxdrawn tillage equipment and post-harvest operation, together with studies of structures for storage of livestock and the effects of tillage operations on the soil.

DEPARTMENT OF SOIL SCIENCE—PROFESSOR OF SOIL SCIENCE. Candidates should possess a good honours degree in agriculture or in a relevant science, as well as postgraduate training in soil science. Considerable experience and competence in teaching and research in soil science and an interest and ability in administration are required. Familiarity with tropical conditions will be a decided advantage. Appointee will take part in the teaching and research programmes of the department. In addition, he will have a major hand in guiding both the teaching and research activities of the department.

DEPARTMENT OF AGRONOMY—(a) PROFESSOR OF AGRONOMY. (b) AGRONOMIST/BREEDER (Cereals). (c) AGRONOMIST (Grain Legumes). (d) AGRONOMIST (Fibres). Candidates for (a) should have a good honours degree in agriculture or a related science. A higher degree or postgraduate training is necessary. Considerable experience in agronomic research, dealing with the principles and practices of crop production and field management, is essential. Administrative ability with academic experience in a university department is required to provide leadership in the teaching and research programme. Appointee will guide the educational and research programmes in all aspects of the growth and development of crops in the areas of agronomy and physiology in a department with an establishment of 24 senior staff. In addition to traditional agronomic investigations, he will organise multidisciplinary studies on the production aspect of farming systems. He will be responsible for the agronomic operation and organisation of experimental trials in the six States, the maintenance of a central repository of records and for statistical services in the Institute. He will be expected to contribute to the teaching programme and its development in the area of his specialisation to students of the Faculty. He will have the opportunity to develop an M.Sc. degree programme for majors in agronomy.

Posts (b), (c) and (d) will be offered at Research Fellow or Assistant Research Fellow level, and candidates should have a good honours degree in agronomy or breeding. A higher degree or evidence of postgraduate experience is necessary for appointment at Research Fellow level. Appointee for (b) must have some knowledge of cereals (primarily maize or sorghum breeding techniques) and be able to conduct field trials leading to improved cereal production. For (c), appointee must be able to conduct agronomic and nutrient research leading to improved production of grain legumes. For (d), appointee will be expected to conduct research with vegetable fibre crops (kenaf, jute, etc.) leading to improved production of fibre. He will also be expected to pay attention to the prospects of paper production from the crops.

DEPARTMENT OF PLANT SCIENCE—(a) RESEARCH FELLOW IN COTTON BREEDING and (b) RESEARCH FELLOW IN HORTICULTURE in the Cotton Breeding and Botany Sections. Candidates for (a) should hold a good first degree in agricultural botany, botany or agriculture and have research experience in plant breeding. Field experience in the tropics would be very desirable. Appointee will initially be stationed at the headquarters of the Institute at Samaru, Zaria, where he will join a team of plant breeders which is charged with the responsibility for the improvement in yield, disease resistance and quality of the cotton crop in the Northern States of Nigeria. Candidates for (b) should hold a good first degree in agricultural botany, botany or horticulture and have research experience, preferably in plant breeding. Field experience in the tropics would be very desirable. Appointee will initially be stationed at the headquarters of the Institute at Samaru, Zaria, where he will be responsible for the onion breeding programme and for research on other crops, including peppers and local vegetables.

Salary scales: Professor N6,600 per annum. Research Fellow N2,760 to N4,830 per annum. Assistant Research Fellow N2,140 to N2,660 per annum. (£1 sterling=N1.59.) The British Government may supplement the salaries of Professors by £1,350 per annum (sterling) for married appointees, or £800 per annum (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. The supplementation is unlikely to be applied to appointments at Research Fellow or Assistant Research Fellow level. Family passages; various allowances; superannuation scheme; biennial overseas leave.

Detailed applications (two copies), including a curriculum vitae and naming three referees, should be sent by airmail, not later than January 22, 1974, to the **Registrar, Ahmadu Bello University, Zaria, Nigeria.** Applicants resident in U.K. should also send one copy to **Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT.** Further particulars may be obtained from either address. (2070)

The **MAX-PLANCK-GESELLSCHAFT** zur Förderung der Wissenschaften e.V. provides in the **Friedrich-Miescher-Laboratorium für biologische Arbeitsgruppen** in Tübingen opportunities for

YOUNG SCIENTISTS

to lead research groups of their own and to carry out independent research programmes for a fixed period of time.

Three out of four of these positions will have to be filled in; one will become available at once and the two others in the fall of 1974.

Applicants should already have done some recognised research in their own particular field, preferably in the areas of **neurobiology** and **cellular differentiation.**

Appointments will be limited to five years. Salaries will fall within the range AH 3 of the Niedersächsisches Besoldungsgesetz (about 45,000 DM per annum).

Each research group will have available approximately 150 square metres of floor space, plus adequate means for scientific and technical supporting staff, basic equipment and operating expenses.

Applications should be submitted before February 15, 1974, to the

Max-Planck-Gesellschaft
zur Förderung der Wissenschaften e.V.
–Generalverwaltung–III a 1–
8000 München 1
Postfach 647, Germany.

(32)

Glaxo

Graduates? HNC?

Make a career in Fermentation Research

Our Fermentation Research Department is located in pleasant parkland surroundings at Sefton Park near Stoke Poges in Buckinghamshire.

We are looking for people to be responsible in our Pilot plant, on a 6 days on—2 day off shift basis, for planning the work of a team of process workers, and supervising plant operations, including the expanding use of modern instrumentation.

Ideally you should be qualified to degree or HNC level in a biological science and be familiar with Pilot scale fermenters, or have a good background in microbiology and aseptic techniques. However we would be prepared to consider those qualified to ONC standard, who have suitable experience.

In addition to an attractive salary, the company, which is a multi-million international group, offers good conditions of employment, including bonus and pension scheme. Assistance with relocation expenses will be given where appropriate.

Please write giving brief career details to: Personnel Officer, REN (Research), Glaxo Laboratories Limited, Greenford, Middlesex.

(47)

Wellcome

Senior Technician

Electron Microscopy

We are looking for a Senior Technician to take charge of the general day-to-day operation of The Electron Microscope Suite. This section is equipped with two electron microscopes, freeze-etching plant, ultramicrotomes and other necessary ancilliary equipment, and provides a service to scientists of all disciplines.

The successful candidate will be between 25 and 35, with at least 5 years' experience of electron microscopy in the biological field, and be capable of working in a multi-discipline environment.

This is an important post and offers excellent conditions of employment and salary commensurate with age, qualifications and experience.

Our Laboratories are situated in pleasant parkland surroundings within easy reach of Beckenham, Bromley and Croydon.

Please write quoting reference U.430 and giving brief details of qualifications and experience to The Senior Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent, BR3 3BS.

1971

(46)

PROFESSOR AND CHAIRMAN
DEPARTMENT OF NUTRITION
UNIVERSITY OF GUELPH

An individual with a scholarly reputation and considerable experience in the biochemical aspects of nutrition is sought for this position. In addition to administrative duties, the Chairman is expected to participate in the teaching activities of the department and to establish his own research programmes. The initial appointment will be for five years, with five year extensions subject to the approval of a review committee. The salary is commensurate with qualifications and experience.

The department is located in the College of Biological Science and currently consists of ten full-time faculty members. It has a strong graduate programme at the M.Sc. and Ph.D. levels and is actively involved in undergraduate teaching. A new B.Sc. degree programme in honours nutrition and biochemistry is being introduced in spring 1974.

Applications, curriculum vitae, and the names of three referees, should be sent to Professor K. Ronald, Dean, College of Biological Science, University of Guelph, Guelph, Ontario N1G 2W1. (28)

CITY OF LONDON POLYTECHNIC
DEPARTMENT OF PHYSICS
LECTURER (GRADE II)

A vacancy exists for a Lecturer (Grade II) who will be required to undertake teaching duties at all academic levels, and in particular to make a substantial contribution to the teaching of the M.Sc. course in optical aspects of molecular and polymer physics. Relevant industrial experience in polymer physics would be an advantage. It is expected that the successful candidate would be appointed from April 1, 1974, but a later appointment is not precluded.

Salary: Lecturer Grade II, £2,515 to £3,243 plus £118 London Allowance.

Further particulars and application form (which should be returned by January 18, 1974) may be obtained from the Assistant Secretary, City of London Polytechnic, 117-119 Houndsditch, London, E.C.3. (49)

UNIVERSITY OF SURREY
VICE-CHANCELLOR

The Vice-Chancellor, Dr. D. M. A. Leggett, has notified the University of his intention to retire on September 30, 1975. The Joint Committee of Council and Senate charged with finding a successor have considered the nature of the appointment and the likely background of the person they hope to find. A note of this information is available.

Persons interested in this appointment are invited to write to the undersigned for a copy. The strictest confidence will be maintained.

P. J. Timms,
Clerk of the University Council,
University of Surrey, Guildford.

(45)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointment:

TEACHING FELLOW IN ELECTRICAL ENGINEERING with interests in communication systems, signal processing, speech analysis, system assessment, power system control, microwave engineering. Interaction with industry is encouraged. (1.2.74.)

Salary scale: Teaching Fellow $A7,270 by $A286 (3) by $A285 (2) to $A8,698; a non-superannuated and non-tenured appointment.

Further particulars about this post and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied to the Registrar, The University of Adelaide, North Terrace, Adelaide, South Australia 5001.

(54)

UNIVERSITY OF LONDON
THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
INSTITUTE OF NUCLEAR MEDICINE

Applications are invited for the post of RESEARCH ASSISTANT to join a group studying hormone target-cell-receptor interactions. The successful applicant will work mainly with gonadotrophins. Experience of cell fractionation procedures is desirable but not essential. Salary, according to qualifications, age and experience, within the range £1,602 to £2,223 per annum plus £162 London Allowance and superannuation under F.S.S.U.

Applications from suitably qualified graduates, including a curriculum vitae and the names and addresses of two referees, to Professor E. S. Williams (N), Institute of Nuclear Medicine, The Middlesex Hospital Medical School, Nassau Street, London W1N 7RL, by January 31, 1974. (17)

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

PROFESSORIAL FELLOW IN ASTRONOMY

Applications are invited for the post of Professorial Fellow in the Department of Astronomy, which operates the Mount Stromlo and Siding Spring Observatory (Head: Professor O. J. Eggen).

At present the main fields of investigation are: photometry and spectroscopy of stars in advanced evolutionary phases, the study of stellar pulsations, interstellar and intrinsic polarization, optical and radio studies of galaxies, the composition of stellar atmospheres, and the study of globular clusters. Theoretical work at present being carried out includes studies of model stellar atmospheres, of the interior structure of stars in advanced evolutionary phases, and of galactic dynamics. Siding Spring Mountain has been selected as the location for the 150-inch Anglo-Australian telescope. Along with other Australian astronomers, the successful applicant may apply for time on this telescope.

In addition to participating in the normal research activities of the Department, the appointee will have special responsibilities for the supervision of scholars and participation, through an instrument committee, of all development (especially electronic) and construction of observatory instruments.

The salary of a Professorial Fellow is $A17,648 per annum. Superannuation is on the F.S.S.U. pattern with supplementary benefits. Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Further information may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **18 February, 1974.** (53)

DALHOUSIE UNIVERSITY

DEPARTMENT OF MICROBIOLOGY

Applications are invited for a Faculty position at the level of LECTURER/ASSISTANT PROFESSOR. Applicants should have an M.D. or Ph.D. with research experience and a major interest in medical microbiology. Salary according to qualifications and experience. Appointment effective July 1, 1974.

Applications to Dr. K. B. Easterbrook, Department of Microbiology, Dalhousie University, Halifax, N.S., Canada, with curriculum vitae and names of three referees. (30)

ICI

Imperial
Chemical
Industries
Limited

Pharmaceuticals Division

Experimental Officer Parasitology

There is a vacancy for a graduate Biochemist to work on the development of biochemical tests, evaluation of potential enzyme inhibitors in fluke and worms, and the exploration of host-parasite metabolic differences as basis for design of drugs. An interest in the application of biochemical knowledge and techniques to biological problems is essential. Practical experience with biochemical techniques is desirable.

The Pharmaceuticals Division is very attractively situated in rural North Cheshire, within easy reach of main road and rail routes. There is a wide range of country and town housing within 20 minutes' drive to cater for most tastes. Conditions of service, career opportunities, and assistance given to married men in moving home are designed to attract and retain staff of high calibre.

Applications in writing, giving details of age, qualifications and experience, should be addressed to:

M F Losse, Personnel Officer
Imperial Chemical Industries Ltd
Pharmaceuticals Division
Mereside, Alderley Park
Macclesfield, Cheshire SK10 4TG

(57)

Organon Research

Organon Research & Development Laboratories are engaged in a broad programme of research, aimed at the development of new drugs.

Organon R & D Laboratories are an international multidisciplinary scientific organization of about 650 collaborators of which 500 are located in Oss, The Netherlands. It maintains close contacts with scientific institutions all over the world.

In the Pharmacological R & D Laboratories, a vacancy has become available for a

Research Oriented Physician

or

Medically Oriented Biologist

The successful candidate will in due course head one of our CNS teams concerned with the study of new psychopharmaca by means of electrophysiological, neuropharmacological or animal-psychological techniques. Development of new methods for the study of mechanisms of action of drugs by means of animal experiments is strongly emphasized.

He will be a creative researcher of 30 to 40 years of age and be familiar with one or more of above mentioned techniques in addition to having a broad pharmacological knowledge. Remuneration will be commensurate with the responsibilities of this important position and the experience of the candidate.

Applications should be directed to the Personnel Department, Organon International BV, P.O. Box 20, Oss (The Netherlands), under No. C. 1464.

Organon

Organon International BV
subsidiary of Akzo Pharma

(11)

MURDOCH UNIVERSITY

Perth, Western Australia

SENIOR LECTURESHIPS AND LECTURESHIPS

Murdoch University, Western Australia's second university, will open in 1975 with about 500 undergraduate students. The university is committed to taking a fresh approach to higher education, with the goal of responding directly to the conditions and needs of the late twentieth century. This will be reflected in admission policies, organisational structures, programmes of study, philosophies of teaching and recruitment of staff. Applications are now invited for up to 30 posts as Lecturer and Senior Lecturer, to take up appointment towards the end of 1974 or early 1975.

Appointments have been made to Chairs in Biology, Chemistry, Education, Environmental Studies, History, Literature, Mathematics, Physics, Social Science, and Veterinary Studies, and further professorial appointments will shortly be made in Animal Biology, Applied Veterinary Medicine, Economics, Psychology, and Veterinary Biology. The university will be organised into six Schools of Study, namely, Schools of Education, Environmental and Life Sciences, Human Communication, Mathematical and Physical Sciences, Social Enquiry, and Veterinary Studies. The undergraduate curriculum will be divided into Part 1 and Part 2 Courses of Study, the Part 1 Course being administered by a university-wide board. A good deal of choice by students will be encouraged and broad contextual courses will be offered, as well as introductory courses in the disciplines forming the foundations of Part 2 programmes of study. Part 2 programmes will be administered largely by multi-disciplinary staff committees. The programmes which it is hoped to offer from 1976 are:

Applied Micro-biology (Industrial)
Biology
Chemistry
Chinese Studies
Communication
Economics
Education
Environmental Science (especially synecology, atmosphere science and waste disposal)
History (especially modern social history)
Human Development (biological, psychological and social)
Indonesian Irenology (the study of conflict and its resolution)
Mathematics
Mineral Science
Physics
Population and World Resources
Veterinary Biology
World Literature

Applications are invited from appropriately qualified persons in all disciplines to participate in introductory teaching at Part 1 level in 1975, and to contribute to the planning and teaching of one or more of the Part 2 programmes from 1976.

The university has decided from the outset to offer external tuition towards degrees. This will be the responsibility of the staff of the schools of study, and the external studies programme as a whole will be coordinated by a Director of External Studies to be appointed in mid-1974.

Along with details of their qualifications, experience, teaching and research interests and publications, applicants should include **in their applications** a note about the programme to which they believe they would be competent to contribute, together with a brief statement of their special interests in these programme areas.

Salaries: Senior Lecturer $A12,268 to $A14,308 per annum; Lecturer $A8,698 to $A11,984 per annum.

Further information about Murdoch University and these appointments, including details of superannuation, travel and removal expenses, housing assistance, study leave and the conditions of employment is available from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Secretary, Murdoch University, Murdoch 6153, Western Australia.

Applications will close on **February 18, 1974.** (52)

SOUTH-EASTERN REGIONAL HOSPITAL BOARD, SCOTLAND

Applications are invited for the new post of **BASIC-GRADE BIOCHEMIST** in the Regional Hormone Laboratory shortly to be established at 2 Forrest Road, Edinburgh, under the direction of Dr E. H. D. Cameron.

The responsibilities of the post will involve the setting up and running of steroid hormone radioimmunoassays as a service for the region, and the successful candidate will be expected to assist in research and development of new techniques.

The Regional Hormone Laboratory is a sub-department of the Department of Clinical Chemistry, Royal Infirmary, and there will be opportunities for staff to rotate for training purposes through this and other clinical chemistry departments in this region if desired.

Further particulars on application.

Applications, which should be typewritten, giving details of age, qualifications and previous experience, together with the names and addresses of two referees, should be sent to the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ, by January 12, 1974. (43)

UNIVERSITY OF LEICESTER

READER OR SENIOR LECTURER IN GENETICS

Applications are invited for the post of READER or SENIOR LECTURER in the Department of Genetics. Applicants should have experience in teaching medical students and an interest in human or medical genetics. The person appointed will be responsible for the development of these aspects of genetics in the department consequent upon the foundation of the new medical school, and will be expected to take part in the promotion of developmental medicine in the teaching hospitals. A medical qualification is therefore desirable but not essential.

Level of appointment and initial salary, dependent on qualifications and experience, within the scale £4,368 to £5,496 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by January 28. (74)

Kings
COLLEGE HOSPITAL GROUP

RESEARCH ASSISTANT

A vacancy exists for an Assistant to a group working on cancer research, experimental radiotherapy of tumours in animals, and growth control mechanisms. Salary according to experience.

Applications to the Principal Technician, Division of Pathology, King's College Hospital, Denmark Hill, London SE5. (20)

KENNEDY INSTITUTE

DIVISION OF EXPERIMENTAL PATHOLOGY

CHIEF TECHNICIAN

A Chief Technician is required to organize and administer the technical services of this active research group concerned with the structure and function of lymphoid tissues combining morphological and biochemical studies, with particular reference to nucleic acids. Appropriate qualifications for the seniority of the post would be required, together with background experience in relevant techniques which include histology, cytochemistry, autoradiography, immunology, tissue and organ culture.

Salary within Whitley Council range for Chief Technicians (£2,589 to £3,132 per annum, plus London Weighting).

Written applications, naming two referees, to: The Laboratory Superintendent, The Kennedy Institute, Bute Gardens, Hammersmith, London W6 7DW. (27)

DEPARTMENT OF BIOLOGY
HARVARD UNIVERSITY

For the forthcoming academic year, this department expects to make at least two appointments at the ASSISTANT PROFESSOR level. Fields of interest include plant biology, genetics, immunology and developmental biology. The university is an equal opportunity employer; women and members of minority groups are specifically encouraged to apply.

Please have three professional persons write us concerning you, and send your résumé, together with your most significant publications prior to February 15, 1974, to Chairman, Department of Biology, 16 Divinity Avenue, Cambridge, Massachusetts 02138. (5)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

Keppel Street, Gower Street, London W.C.1

Clinical Nutrition and Metabolism Unit

READVERTISEMENT

TECHNICIAN, graduate or H.N.C., required immediately to join an M.R.C. supported group studying problems of biochemical adaptation in relation to obesity and surgical trauma. The group is situated at the Hospital for Tropical Diseases, St. Pancras, N.W.1. Applicants should have a good biochemical background and laboratory experience. Salary, according to qualifications and experience, within the scale £1,440 to £1,845 plus £126 London Weighting.

Applications, consisting of full curriculum vitae and naming two referees, should be sent to the Secretary (A1) at the School. (16)

COLÁISTE NA hOLLSCOILE, GAILLIMH

(UNIVERSITY COLLEGE, GALWAY)

University Senior Technician/ Electronics Technician

with an interest in telecommunications required in a University Department. City and Guilds qualifications or equivalent necessary.

Apply to:

Professor of Physiology,
University College,
Galway. (64)

UNIVERSITY OF CALGARY

Applications are invited from students wishing to conduct GRADUATE STUDIES IN BIOLOGICAL SCIENCES for the Ph.D. or M.Sc. degree. Successful applicants may compete for Teaching and Research Assistantships which carry a stipend, remission of fees and a travel allowance.

For further information write to: The Secretary for Graduate Studies, Department of Biology, University of Calgary, Calgary T2N 1N4, Alberta, Canada. (36)

CORNELL UNIVERSITY

SECTION OF NEUROBIOLOGY AND BEHAVIOUR

Cornell University is seeking a ZOOLOGIST (Ethologist) specializing in animal social behaviour, with an emphasis on the field approach. Teaching and research duties. Assistant Professor rank, salary negotiable. Send credentials or inquiries to:

Professor William T. Keeton, Chairman,
Section of Neurobiology and Behavior,
Cornell University,
Ithaca, New York 14850.

Cornell University is a non-discriminatory, equal opportunity employer. (51)

M.R.C. MINERAL METABOLISM UNIT

THE GENERAL INFIRMARY LEEDS

GRADUATE in one of the biological sciences required to work on the biochemistry and physiology of vitamin D and other aspects of calcium metabolism. Salary according to age, experience and qualifications.

Please apply with details of qualifications to the Director. (24)

UNIVERSITÄT ZU KÖLN GERMANY

INSTITUT FÜR GENETIK

E. COLI GENETICIST

A post-doctoral research position for work in association with Professor B. Müller-Hill will be available immediately. The appointment will be for two to three years. The salary will be on the scale of ca. 27,000,— DM per annum.

Applications, with curriculum vitae and the names of two referees, should be sent to Professor B. Müller-Hill, Institut für Genetik der Universität zu Köln, Köln 41, Weyertal 121, West Germany. (25)

AQUATIC ECOLOGIST

Appointment available at Rosenstiel School of Marine and Atmospheric Science, University of Miami, for an Aquatic Ecologist interested in quantitative population or community ecology, with particular interest in food chain dynamics and community structure. Responsibilities will include teaching and the designing and co-ordination of field research. Level of appointment would be commensurate with qualifications.

Inquiries should be submitted to:

James H. Carpenter,
Chairman, Search Committee,
R.S.M.A.S., University of Miami,
10 Rickenbacker Causeway,
Miami, Florida 33149.

The University of Miami is an equal opportunity/affirmative action employer. (26)

UNIVERSITY HOSPITAL OF WALES

HEATH PARK, CARDIFF

Applications are invited from suitably qualified people for the post of MEDICAL LABORATORY TECHNICIAN in the Department of Haematology at Cardiff Royal Infirmary. Duties will include assistance with routine microbiological assays and with the current investigation into the automation of these techniques.

APPLICATIONS: Application forms available from the Personnel Department. (18)

UNIVERSITY OF CALGARY, GRADUATE Teaching and Research Assistantships are available for students proceeding to the Ph.D. or M.Sc. degrees in all branches of Chemistry and Biochemistry. The Assistantships are valued from $4,100 to $5,000 per annum and carry remission of programme fees and travel allowance.

For further information write to: Department of Chemistry, Calgary, Alberta T2N 1N4, Canada. Please indicate field of interest. (X35)

ROYAL POSTGRADUATE MEDICAL SCHOOL

GRADUATE SCIENTIFIC OFFICER/TECHNICIAN required in Immunoassay Laboratory of the Endocrine Unit. Candidates should possess good biochemical and isotope qualifications and laboratory experience, preferably in a similar post. Salary, according to qualifications and experience, in range £1,600 to £2,300.

Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, DuCane Road, W12 0HS, quoting reference 4/111/N. (70)

Overseas Appointments

BELIZE

Tobacco Officer:

To initiate production amongst small holders, and provide advice to growers; to train local staff and assist with trials. Applicants should have experience with Virginia and Burley tobacco, and be experienced in the prescribed duties of the post.

Salary in scale £3,000–£4,500 p.a. plus a tax free overseas allowance in scale £435–£1,145 p.a. Appointment for 2 years.

BRAZIL

Professor of Forestry:

At the Federal University to lecture to post-graduate students on forest management and land use; to supervise research projects. Applicants should hold relevant post-graduate qualifications and be experienced in the prescribed duties of the post; knowledge of forest ecology an advantage but not essential. Appointment of 2 years.

Salary in scale £4,500–£6,400 p.a. plus a tax free overseas allowance in scale £650–£1,390 p.a.

ST VINCENT

Agricultural Engineering Technician

To undertake technical back-up to arrowroot harvesting; advise on introduction of field machinery; advise on irrigation and soil conservation; and conduct relevant training courses. Applicants aged 25–40 should be professionally qualified in Agricultural Engineering Technology and have practical experience in the prescribed duties of the post. Appointment for 2 years.

Salary in scale £2,400–£4,000 p.a. plus a tax free overseas allowance in scale £750–£1,435 p.a.

Other benefits include free family passages, paid leave, children's education allowances and free accommodation and medical attention. Applicants should normally be citizens of, and permanently resident in, the United Kingdom. All emoluments paid by British Government.

For full details together with an application form and booklet about the country concerned please apply giving details of age, qualifications and experience to:—

COLLEGE OF PHARMACY
FACULTY OF HEALTH PROFESSIONS
DALHOUSIE UNIVERSITY, CANADA

ASSISTANT PROFESSOR IN PHARMACEUTICS

Ph.D. in Pharmaceutics with major in Physical Pharmacy required for July 1, 1974, for a new faculty position. Teaching and research experience desirable. Research actively encouraged. Salary according to experience and qualifications.

Applications in the form of a letter accompanied by a curriculum vitae and the names and addresses of three referees should be sent to Dr R. S. Tonks, Director, College of Pharmacy, Dalhousie University, Halifax, Nova Scotia.

(50)

STATISTICAL TECHNIQUES

The Company is expanding the development and production of clinical assay kits utilising radioisotopes. New techniques and approaches are constantly being examined for the quality control of these products and we need a statistician to advise and collaborate with scientists and technologists in these areas.

The ideal person for this post would probably be aged 26-32 and have an honours degree in statistics. Experience in a scientific or bio-medical environment is desirable though not essential. Applications are also invited from suitably qualified but perhaps less experienced people who feel ready for the challenge of being the sole professional statistician in a multi-disciplinary team.

Good computing facilities are available, and it is intended that, whilst clinical assay will be the prime area of involvement, the person appointed will increasingly bring his professional approach to bear on other aspects of the Company's work.

A starting salary of up to £3500 is envisaged (it could be higher for the exceptional person) on a progressive scale offering prospects to £4900 and beyond.

Please write to or ring Dr. T. E. Forster for an application form and further particulars. (Telephone Little Chalfont 4444).

The Radiochemical Centre

Amersham Bucks

(19)

SOUTH-EASTERN REGIONAL HOSPITAL BOARD, SCOTLAND

Applications are invited for the new post of **SENIOR GRADE BIOCHEMIST** in the Regional Hormone Laboratory shortly to be established at 2 Forrest Road, Edinburgh, under the direction of Dr E. H. D. Cameron. The responsibilities of the post will involve supervision of service protein hormone assays, and every opportunity will be afforded to the successful candidate to undertake research and development of new techniques, and to cooperate in clinical research programmes.

The Regional Hormone Laboratory is a sub-department of the Department of Clinical Chemistry, Royal Infirmary, and there will be opportunities for staff to rotate for training purposes through this and other clinical chemistry departments in this region if desired.

Further particulars on application.

Applications, which should be typewritten, giving details of age, qualifications and previous experience, together with the names and addresses of two referees, should be sent to the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ, by January 12, 1974. (42)

INSTITUTE OF CONNECTED EDUCATION

offer prizes for research in pure general science. That is, research in interdisciplinary sciences, or if and how all sciences are interconnected. Main object of the Institute is to create and sponsor the acceptance of a course of this nature in schools, colleges and institutes.

For further information please apply in writing to: **The Secretary, Institute of Connected Education, 28a Cadogan Place, London SW1X 9RX.**

(40)

PONTEFRACT, CASTLEFORD AND GOOLE HOSPITAL MANAGEMENT COMMITTEE

BIOCHEMIST BASIC GRADE

required—Pontefract General Infirmary. Well-equipped department in developing general hospital. New maternity unit recently commissioned. Training will be given in all branches of clinical biochemistry, and specialisation encouraged. Starting salary according to qualifications and relevant postgraduate study or research. On scale £1,380 to £2,122 per annum, during probationary period of at least two years, thereafter subject to a certificate of proficiency to a maximum of £2,517.

For further information and arrangements to visit contact Mr R. Lockwood, Principal Biochemist, tel. Pontefract 72361, ext. 238. Applications, giving full details and naming two referees, to Group Secretary, Churchill House, 29 Mill Hill, Pontefract, by January 14, 1974. (68)

UNIVERSITY COLLEGE LONDON CHEMISTRY DEPARTMENT

TECHNICIAN (GRADUATE) to assist in research involving wide line (other-nucleus) N.M.R. Interest in electronics essential. Post is financed by S.R.C. and has not less than 2 years to run in the first instance. Salary range £1,650 to £1,920, plus £175 London Allowance.

Applications to Mr. F. Widdas (N), Department of Chemistry, University College London, 20 Gordon Street, London WC1H 0AJ. (15)

UNIVERSITY OF MANCHESTER

RESEARCH ASSISTANT IN THE DEPARTMENT OF CHILD HEALTH

Applications invited for this post from graduates, preferably with post-doctoral experience, to work on tissue culture of endocrine pancreas. Experience in cell biology, endocrinology or biochemistry an advantage. Appointment is for two years from March 1, 1974. Salary range £2,718 to £3,048 per annum. F.S.S.U.

Particulars and application forms (returnable by January 18, 1974) from Dr. R. D. G. Milner, St. Mary's Hospital, Manchester M13 0JH. (60)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

HIGHER SCIENTIFIC OFFICER required by the Microbiology Division to take charge of the media laboratory which provides media and other microbiological services for the various research groups in the Institute.

Qualifications: H.N.C. or pass degree in appropriate subjects, plus at least five years' relevant post-qualification experience, including extensive experience of media laboratory practice. Experience of managing a small working team an advantage.

Starting salary: £2,076, rising by seven increments to a maximum of £2,667. In addition, a supplement of 5½ per cent is paid to offset superannuation contributions.

Superannuation: Optional Contributory scheme.

Application form and further details from the Secretary, Food Research Institute, Colney Lane, Norwich NOR 7OF, quoting Ref. 73/26. (69)

MARINE SCIENCE TEAM

Geological Oceanographer-Geophysicist, Ph.D., 20 years' experience in continental shelf exploration, research and teaching, with numerous publications and some patents pending, and **Biological Oceanographer,** M.Sc., specialist in marine microbiology and pollution, presently teaching and operating own research vessel in the eastern Mediterranean, are interested in becoming associated with an aggressive, developing research, academic or industrial organisation, preferably Europe or Mediterranean area.—Write Box 2079, Nature, T. G. Scott & Son Ltd., Clement's Inn, London WC2A 2ED. (7)

UNIVERSITY OF READING, LECTURESHIP IN GEOLOGY. Applications are invited for a Lectureship in Geology. Candidates will be expected to teach in sedimentology and closely related areas, and to have a major research interest in the chemical and/or biological aspects of this field. The person appointed should take up duties on October 1, 1974.—Further information may be obtained from the Registrar (Room 208, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, and applications should reach him not later than **February 4, 1974.**

(33)

Manager

(Precious Metal Catalyst Research)

Johnson Matthey, as the world's major refiner and fabricator of the platinum metals, has extensive interests in the development of catalysts and catalytic processes for use in pollution control and in the chemical and pharmaceutical industries.

Arising from an internal promotion, applications are invited for the post of Manager, Catalyst Research Department, at the Group Research Laboratories, Wembley, Middlesex. The person appointed will report to the Manager, Research, for the organisation and management of the Catalyst Department and research programme. This will involve close liaison with Sales and Development Groups of Operating Companies within the Johnson Matthey Group, in the selection and commercial exploration of research projects.

The post will be particularly attractive to those aged between 30-45 with previous industrial experience in catalyst research and development, or who have a proven record of academic achievement and are now interested in applying their experience in an industrial field.

The commencing salary will be commensurate with the senior level of this appointment, and other conditions of employment and fringe benefits are in keeping with large Group practice.

Applications giving brief but comprehensive career details should be addressed to: **Director of Research (ref. SJTH), Johnson, Matthey & Co., Limited, 78 Hatton Garden, London, EC1P 1AE.** (78)

INVERESK RESEARCH INTERNATIONAL. **PHARMACOLOGIST.** Inveresk Research International is a rapidly expanding contract research organisation operating in the pharmaceutical, chemical, food and related industries. Due to expansion in our pharmacology section, a vacancy now exists for a young graduate Pharmacologist. This position offers an exciting opportunity to gain wide experience in many aspects of pharmacology.—Application in writing, which will be treated in strict confidence, should be sent to Inveresk Research International, Inveresk Gate, Musselburgh EH21 7UB. Ref. PAB/P. (55)

INSTITUTE OF CANCER RESEARCH: Department of Physics. PHYSICIST or ELECTRICAL ENGINEER required at Belmont, Sutton, Surrey, to assist in the development of novel techniques in (a) X-ray image formation for medical diagnosis and (b) studies of the action of ionising radiation on biological materials using short pulse irradiation. some research or industrial experience with ionising radiation would be an advantage but not essential. Salary on M.R.C. scales Grade II, depending on qualifications and experience.—Apply in duplicate, giving curriculum vitae and quoting two referees, to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting Ref. No. 300/G/65. (61)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from suitably qualified candidates for the above post.

The person appointed will be engaged on a project supported by the Medical Research Council involving the study of steroid hormones secreted by the ovary under *in vitro* superfusion conditions.

The appointment will initially be for 18 months, and the post will be available from April 1, 1974. Salary in the range £1,929 to £2,223.

Applications, with a curriculum vitae, together with the names of two referees, and quoting Ref. R35/73, should be sent to Dr J. Watson, Department of Biochemistry, University of Strathclyde, 204 George Street, Glasgow G1 1XW. (38)

UNIVERSITY OF READING, LECTURESHIP IN GEOGRAPHY (readvertisement). Applications are invited for a Lectureship in Geography. Applicants should be competent in hydrology and/or microclimatology. The person appointed should take up duties on the earliest date which can be arranged.—Further information may be obtained from the Registrar (Room 208, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, and applications should reach him not later than **January 31, 1974.** (34)

GRANTS & SCHOLARSHIPS

THE ROYAL SOCIETY
THE RUTHERFORD SCHOLARSHIP

Applications are invited from graduates of a university within the British Commonwealth who are under 26 years of age, or if holding the degree of Ph.D. under 28 years of age on May 1, 1974, for the RUTHERFORD SCHOLARSHIP. This will be awarded for experimental research in any branch of the natural sciences, but if there are candidates of similar merit preference will be given to experimental physics. The scholarship will be tenable for three years in some part of the British Commonwealth other than that in which the applicant graduated. It will not normally be awarded to a graduate who has already held a senior research award.

The value of the scholarship will be adjusted to meet the circumstances of the appointment, but if held in the United Kingdom it will be between £950 and £1,200 per annum (or up to £1,600 per annum for post-doctoral candidates). Additional allowances will be granted for travel, university fees, etc. The appointment will date from October 1, 1974, or such other date as may be arranged.

The appointment will be made by the President and Council of the Royal Society. Application from university graduates outside the United Kingdom should be made through their universities to the Royal Commission for the Exhibition of 1851 on forms of application for the 1851 Exhibition Science Research Scholarship. Application from university graduates in the United Kingdom should be made before February 15, 1974, on forms obtainable from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. 5 Köln-Vogelsang

POSTDOCTORAL RESEARCH FELLOWSHIP

A scientist is required for a three-year period to study tissue and anther culture of dihaploid and tetraploid potatoes. He will join a team already engaged in similar studies on *Petunia, Nicotiana,* barley and carrot. Previous relevant experience is desirable. There will be an opportunity of becoming acquainted with potato breeding at the dihaploid level. Because of housing difficulties a single person is preferred. Salary on BAT scale from DM26,930 to DM28;990 per annum according to age.

Applications, giving full bibliographical details and the names of two referees who may be contacted should be sent to Professor H. Ross. (41)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF CHEMICAL ENGINEERING AND FUEL TECHNOLOGY

POST-DOCTORAL FELLOWSHIP AND RESEARCH ASSISTANT

Applications are invited for a Post-Doctoral Fellowship in the field of Air Pollution from Aircraft. The research work is supported by a grant from the United States National Aeronautics and Space Administration and will be carried out as part of a joint research project with the Department of Mechanical Engineering at the Massachusetts Institute of Technology in Boston. Experiments will be carried out at Sheffield University on the combustion efficiency and pollution characteristics of swirler modules used in the N.A.S.A. gas turbine combustion chambers. Velocities will be measured in the flames by a laser anemometer, and temperatures and gas concentrations will also be measured in the flames. Provision is made in the budget to allow visits to M.I.T. and N.A.S.A. Research Centres in the United States. Initial salaries are according to experience, up to £3,048 for the Post-Doctoral Fellow and up to £2,058 for the Research Assistant. The Research Assistant may be able to register for a Ph.D., in which case a limited salary will be imposed.

Applications, giving the names of two referees, should be sent to Dr N. A. Chigler, Reader in Chemical Engineering and Fuel Technology, The University, Sheffield S1 3JD. Please quote Ref. R12/G1. (66)

Dalhousie University

HALIFAX, NOVA SCOTIA, CANADA

The Izaak Walton Killam Memorial Scholarships

1974-75

Value
Scholarships valued at $4,500-5,000 and renewable on evidence of satisfactory performance in a Master's or Doctoral program in the natural sciences, social sciences and humanities, are tenable at Dalhousie University.

Qualification
Eligibility is based on a first class undergraduate degree in the field of study the student wished to pursue. No remission of fees accompanies the scholarships but travel assistance to Dalhousie is available. Scholars may perform instruction or demonstration duties at the discretion of the department for which additional remuneration is given.

Application
Candidates are not required to submit application forms for the Killam Memorial Scholarships, but should apply for admission to the Registrar, Dalhousie University, Halifax, Nova Scotia, Canada, as early as possible.

On the basis of the information supplied in the application, the graduate department concerned will nominate the scholar to a selection board for consideration and nomination for a Killam award.

The Izaak Walton Killam Fund for Advanced Study at Dalhousie University was founded by Mrs Dorothy J. Killam in memory of her husband Izaak Walton Killam. Her purpose was to establish a perpetual memorial to her husband in his native province and "to help in the building of Canada's future by encouraging advanced study".

Please quote code no. 313 in your application.

SSRC

Social Science Research Council

FELLOWSHIPS 1974

The Social Science Research Council offers a number of Fellowships starting October 1974, or at latest January 1975. They are tenable for one or two years.

SENIOR RESEARCH FELLOWSHIPS are for well-qualified candidates (normally holding a good Honours degree) with seven or eight years' experience in a professional capacity, for postgraduate research training in the social sciences. The Fellowships are not intended for staff of universities or independent research institutes, though applications from serving teachers in other institutions will be considered. Awards are worth from £1,764 to £2,715 (taxable). In certain circumstances awards may be tenable at independent research institutes.

CONVERSION FELLOWSHIPS are intended to encourage Ph.D.s from outside the social sciences to "convert" by providing postgraduate training in the social sciences (or more rarely to move from one social science to another). People who have been awarded these Fellowships in the past few years include Ph.D. chemists, scientists or technologists who have wanted to enter a variety of social science postgraduate fields.

Information is obtainable from the SSRC, Room 6, 11 New Fetter Lane, London EC4A 1AY. (Tel.: 01-405 6491, ext. 316.) Please quote reference FS/N.

CLOSING DATE FOR COMPLETED APPLICATIONS
1st MARCH 1974

(12)

ABSTRACTOR

A graduate in microbiology, biochemistry or allied subjects is required for full-time abstracting work.

Please apply to: Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (8)

ABSTRACTORS/TRANSLATORS

Graduates in microbiology, biochemistry or allied subjects with a good knowledge of either French or German are required for full-time abstracting work.

Please apply to: Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (9)

THE POLYTECHNIC OF
CENTRAL LONDON

DEPARTMENT OF PHYSICS

P.C.L. Research Studentship

£1427–£1537

tenable for three years from September 1974 or sooner if possible. The successful candidate will investigate the Track Structure of Ionisation Radiation, using a Low Pressure Cloud Chamber. The work will be carried out in the Environmental and Medical Sciences Division at Harwell, and the student will be expected to register for the degree of Ph.D. (C.N.A.A.). Applicants should be honours graduates or expect to graduate before September 1974.

Details and application form from The Establishment Officer, The Polytechnic of Central London, 309 Regent Street, London W1R 8AL. Closing date February 8, 1974. Please quote reference N.

(65)

ASSISTANTS AND FELLOWSHIPS

available for graduate study in materials science and engineering leading to M.S. and Ph.D. Research areas include mechanical properties, crystal growth, surfaces, corrosion, electronic properties, biomaterials, fuel cells and batteries, phase transformations and materials synthesis and processing.

For information write: Chairman, Department of Materials Science and Engineering, Stanford University, Stanford, California 94305. (37)

LECTURES AND COURSES

UNIVERSITY OF SOUTHAMPTON
SHORT COURSES IN
APPLIED PHOTOCHEMISTRY

Three one-week intensive courses on the following subjects are to be held on the dates shown:

March 25 to 29, 1974—Environmental and Analytical Problems.
April 1 to 5, 1974—Polymer Photochemistry.
April 8 to 11, 1974—Image-forming processes.

For further details of courses and fees write to:

Dr. D. Phillips,
Department of Chemistry,
The University,
Southampton SO9 5NH. (44)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MEDICAL PHYSICS
M.Sc. IN MEDICAL PHYSICS

The Department provides a 12 months' course in Medical Physics, commencing October 1 each year. Candidates should have a first or second-class honours degree in Physics or Electronics or Engineering, or equivalent qualifications.

The course covers a wide range of the applications of physics to medicine and is designed to prepare candidates for a career in Medical Physics.

The Science Research Council and Medical Research Council have accepted the course as suitable for the tenure of their Advanced Course Studentships. The course has been endorsed by the Departments of Health in London and Edinburgh.

Further details available from the Secretary, Department of Medical Physics, University of Aberdeen. (X77)

The
Ribonucleic
Acids

Edited by **P. R. Stewart** and **D. S. Letham**
With 56 figures. XV, 268 pages. 1973
Cloth DM 45,40; US $18.70

Prices are subject to change without notice

This textbook sets out to close the gap between the rather general approach of biochemistry texts and the bewildering diversity of research reports on the role of RNA in living cells. It presents modern concepts of cell differentiation from the point of view of the processes going on at molecular level, and the key role of RNA in the transfer and decoding of genetic information. Established biochemists and microbiologists will find this work a help in updating their knowledge, and it will be of considerable interest to workers in virology, cell biology, and genetics.
Other biologists, organic chemists, and biophysists could use the book as an introduction to a new field.

Contents
D. S. Letham, P. R. Stewart, and G. D. Clark-Walker: RNA in Retrospect. – G. M. Polya: Transcription. – H. Naora: Nuclear RNA. – A. J. Howells: Messenger RNA. – D. S. Letham: Transfer RNA and Cytokinins. – L. Dalgarno and J. Shine: Ribosomal RNA. – G. D. Clark-Walker: Translation of Messenger RNA. – P. R. Stewart: Inhibitors of Translation. – P. R. Stewart: Mitochondrial RNA. – P. R. Whitfeld: Chloroplast RNA. – A. J. Gibbs and J. J. Skehel: Viral RNA. – R. Poulson: Isolation, Purification and Fractionation of RNA. – Subject Index.

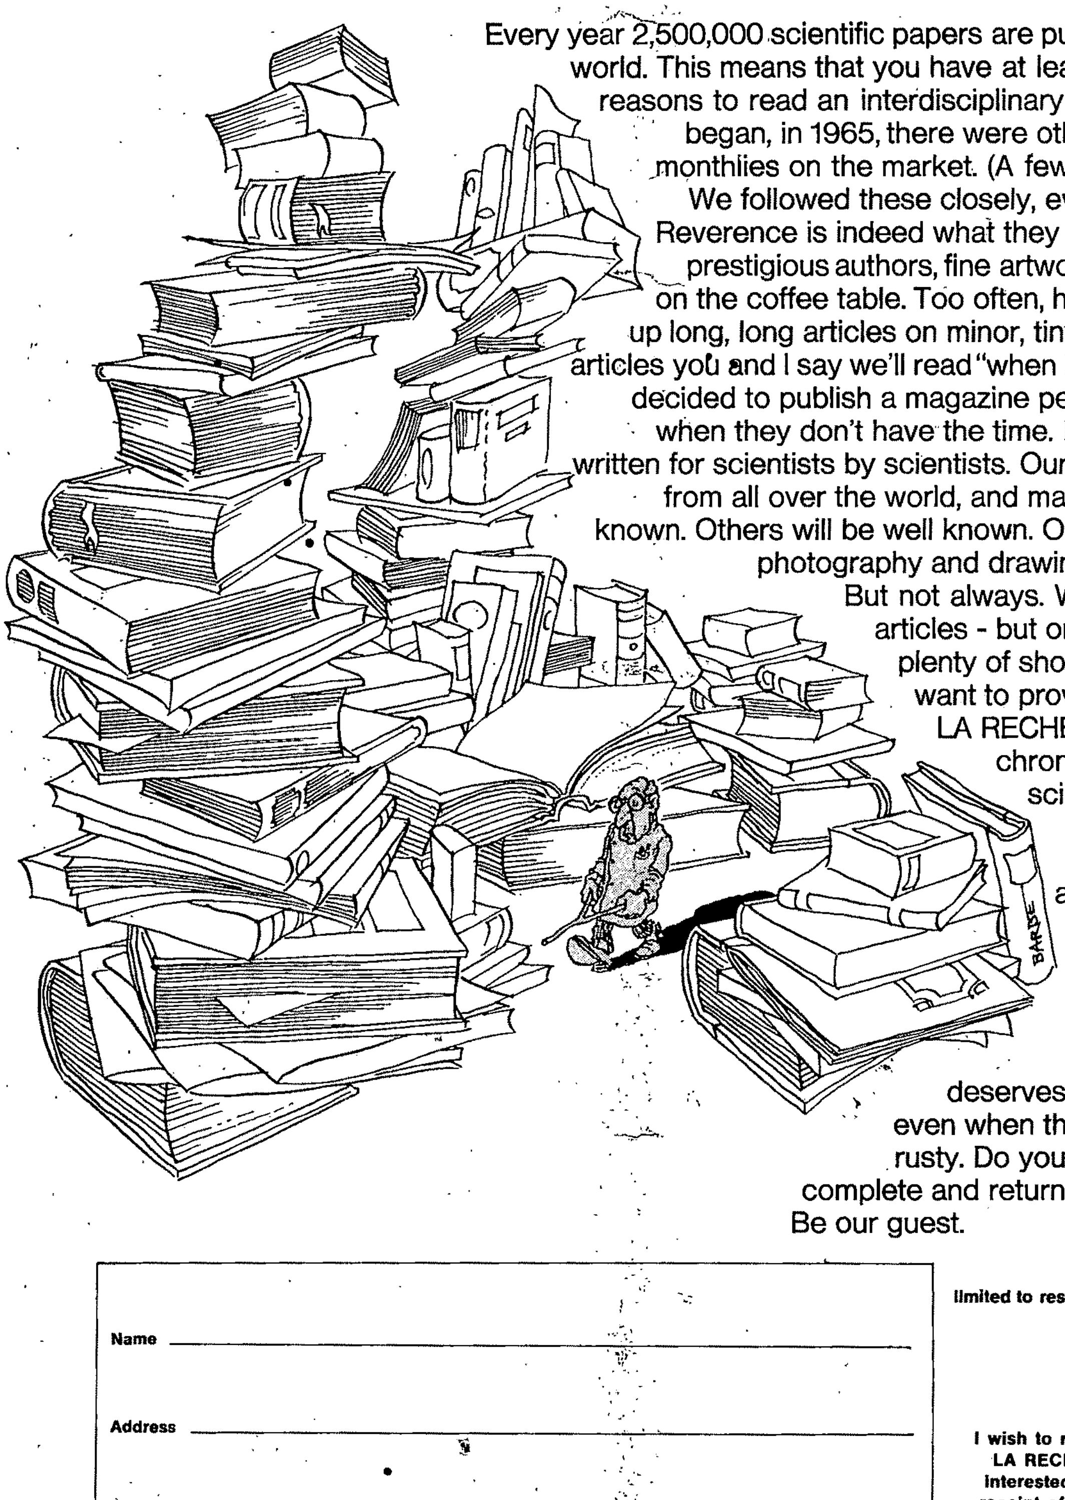
vous avez au moins 2 500 000 bonnes raisons de lire La Recherche



Every year 2,500,000 scientific papers are published all over the world. This means that you have at least 2,500,000 good reasons to read an interdisciplinary monthly. When we began, in 1965, there were other interdisciplinary monthlies on the market. (A few of these still exist). We followed these closely, even with reverence. Reverence is indeed what they deserve. They have prestigious authors, fine artwork: They look good on the coffee table. Too often, however, they serve up long, long articles on minor, tiny subjects. Just the articles you and I say we'll read "when I have the time". We decided to publish a magazine people will read even when they don't have the time. LA RECHERCHE is written for scientists by scientists. Our contributors come from all over the world, and many of them are well known. Others will be well known. Our artwork includes photography and drawings. Mostly serious. But not always. We have some long articles - but on major topics. And plenty of short articles. What we want to provide every month in LA RECHERCHE is a running chronicle of international scientific news across the board, from biochemistry to astronomy. Readers in 78 countries seem to think that we give them just that and that LA RECHERCHE deserves thorough reading... even when their French is a little rusty. Do you want to try it? Just complete and return the coupon below. Be our guest.

Where there's a radiochemical need...

Whatever type of radiochemical product – labelled compound or isotope:
Whatever the specifications you require for your particular application – ultra-high specific activity, low specific activity with high stability, specially high purity or specially positioned labels:
However quickly you need it:
It is reassuring to know that your local distributor can almost certainly supply it immediately – if not directly from his own stock then by fast air freight from Amersham.
It is even more reassuring to know that when you n
technical assistance or advice, no matter where in
world your laboratory is situated a call to your l
distributor can not only arrange prompt delivery of exa
the labelled compound you need – it can also mob
for you the full resources of The Radiochemical Cer
Amersham.

there's The Radiochemical Centre.

ur experienced technical staff are always ready to advise u, in writing or in person – they have already visited stomers in more than 40 countries and will travel well ver half a million kilometres during next year. They are ll working scientists in the laboratories at Amersham, here they maintain a constant familiarity with the products, oduct applications, and customer problems.

ext time you need a labelled compound, remember that e Radiochemical Centre is as close as your local distributor. It's all part of the unique service that adds up to real value for money.

We'll gladly send you the name of our distributor in your country, please write.

And our associate companies are always ready to help.

Nuclear Magnetic Resonance (N.M.R.) in Biochemistry

Applications to Enzyme Systems

Raymond A. Dwek

How far can one use n.m.r. to determine the complete three-dimensional structure of an enzyme in solution? Can n.m.r. studies help to identify the functional groups involved in catalysis, the nature of the transition state, and the role of metal ions and co-factors? This book attempts to answer these and related questions, and with examples discusses the information that different types of magnetic resonance measurements can give. It will be found useful by biochemists, protein chemists, enzymologists, biophysical chemists, and inorganic chemists, at the advanced student and research levels. £8
Monographs in Physical Biochemistry

The Many-Body Problem

W. E. Parry

This book provides an introduction to the techniques used in the study of the many-body problem, and will serve as a reference book for those techniques. Diagrammatic perturbation theory, the equation of motion method, pair-wave approximations, and the theory of linear response with its application to transport theory, are the basic techniques described. Several different formulations of the techniques, and their interrelations, are discussed, to prepare the reader for the published literature. £6·25
Oxford Studies in Physics

Strong Solids

A. Kelly

This completely revised edition takes account of the tremendous increase in activity in the field of strong materials since the first edition appeared. The book deals with the physical principles governing the production of a strong solid. The possible strength of a material can be deduced from a knowledge of chemical binding forces. The effects of imperceptions on strength are dealt with and the ways available to reduce their effects are explained succinctly and accurately for polymers, metals, ceramics, and composite materials. Second edition £7
Monographs on the Physics and Chemistry of Materials

Partially Ordered Topological Vector Spaces

Yau-Chuen Wong and Kung-Fu Ng

This is an account of the duality theory of partially ordered topological vector spaces. In particular, the two most satisfactory aspects of the theory, namely partially ordered Banach spaces and locally convex Riesz spaces, are treated in detail. Some material; based on the authors' own research spaces, are treated in detail. £7
Oxford Mathematical Monographs

Oxford

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système Internationale. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

WE regret that as a result of the imposition of a three-day working week on industry in Britain it has not been possible to produce a *Nature* of more than 64 pages this week. The crisis shows no sign of abating in the near future and so next week's issue will also be of 64 pages. The 25th January issue, however, is planned to be up to 96 pages and thereafter we hope to be able to produce at least this number of pages each week for the duration of the present emergency.

The London office continues to be open five days a week, albeit candlelit on two of them, and manuscripts are being handled normally.

Mr John Hall has been appointed News Editor of *Nature*. A former London staff member of *The Guardian*, Mr Hall was until recently a freelance writer supplying feature material to *The Guardian Weekly* and other newspapers and magazines in London and abroad.

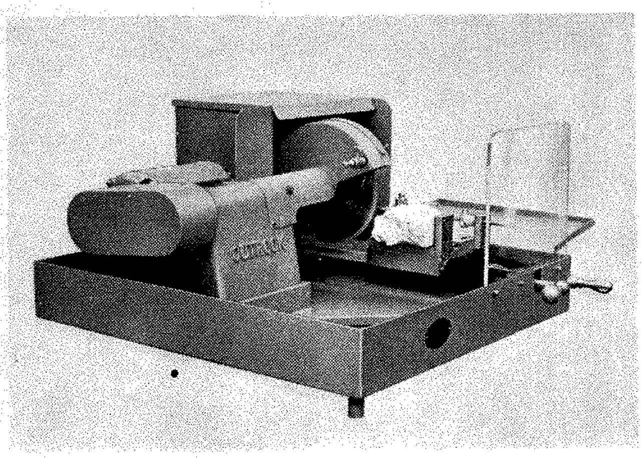
CUTROCK

Diamond or Abrasive Wheel Cut-off Machine MODEL GSP 210

Cuts Rock, Refractories Ceramics Glass or Metals



A simple to operate machine with application in all fields where hard materials are cut.

The vice unit will grip either regular or irregular specimens, and has a detachable vee jaw for clamping rods, cores or tubes.

Coolant pipes on both sides of the cutting wheel supply ample cooling during cutting. The machine can be supplied with a settling tank and pump unit if required.

Additional equipment—cross slide with $2\frac{1}{2}$" movement.

High speed vibration free taper roller bearing spindle.
Standard Cutting Wheels, 8" diameter × 1/16" or 1 mm wide.
Area of cut 5" × $2\frac{1}{2}$"—Drive flat nylon belt.—
Dimensions—length 30", width 28", height 16". Wt. 1 cwt.

Crisis leads to change

THE outlook from every capital city must at present be bleak and yet nowhere can the immediate prospects be more depressing than in London. Although the rise in the price of oil and restrictions on its supply have hit all countries and the long-term problems of price are terribly serious for developing countries, the industrialised nations are the first to feel the pinch. Britain with its natural gas and coal resources should be marginally better equipped than most other European countries to cope with oil shortages, but it has contrived to compound shortages by virtue of two industrial actions—of the coal miners and of railway engine drivers.

The miners present the bigger problem. Their action has the deeper impact on the country over the longer term and the first effects are now being seen. There is little doubt, despite the inevitable and rather silly political sparring, that coal supplies were falling to a dangerous level and electricity supplies would have been jeopardised by early February. To avoid this the government has imposed a three-day working week throughout industry. The industrial chaos that this is rapidly leading to is deemed necessary in order to maintain vital services up to the end of the winter. It is obvious that one of the purposes of the three-day week has been to prevent coal supplies being run down, as they were in 1972, to a level at which the miners could strike and get exactly what they wanted. There is considerable public sympathy for the miners, whose pay structure contains glaring anomalies.

The government meanwhile pursues its implacable course. Stage Three of its anti-inflation policy, originally heralded as offering flexibility in the negotiation process, is only three months old and seems to offer no negotiating possibilities. Unions have determined to ignore Stage Three in putting in wage claims and the situation is deadlock—so much so that to the exasperation of the public, meetings between the sides are rare, as there is nothing to talk about. During this sleep of reason, the participants seem to have allowed themselves to be saddled with two burdens which sensible negotiators could have avoided—lack of fall-back positions and problems of serious loss of face in the event of failure.

As a result of this, whereas all countries are experiencing hardships, Britain is in danger of falling apart.

The political scene will perhaps emerge as the most damaged. For the past two or three years politicians the world over have been dismayed by the rise in world commodity prices which has taken from them much of their ability to control national economies. This in itself need not discredit the politicians provided a certain amount of frankness is maintained about what governments can and cannot do. Frankness is not, however, a mark of the British politician. Political posturing over inflation has now also become posturing over energy and the three-day week. There is a growing disbelief in the country that either major political party can be turned to in a crisis like this for a cool and lasting solution.

Socially, the danger signals are beginning to appear. The longer-term consequences of the present crisis—a depressed standard of living, less expenditure on desirable projects and so on—are not yet at hand but the short-term indicators, such as the way people behave, are ominous. Just as the bad economic times of the 1920s and 1930s left a mark on the personality of a generation, so the present trauma of crisis, confrontation, divisiveness and inflation may leave a scar of bad temper and distrust.

The military impact of the energy crisis for countries such as Britain lacking local oil supplies is worth comment. It does not seem likely that any such nation will be able to conduct warfare which is displeasing to oil producers without being quickly throttled. The contrast with Suez in 1956 when the retaliation was short-lived is striking. If the crisis thus simply imposed more restraints on military ventures it could be reckoned a good thing. Power to prevent, however, also implies power to promote. Only time will tell whether oil producers can dictate the military activities of other nations.

What are the prospects for science? As we report elsewhere the first impact of budget cuts is now being felt in research spending. This budget was produced before it was clear that the three-day week was a relatively long-term affair. Another month of this and further cuts in public spending may be necessitated. Customer-oriented science is probably a less attractive target for cuts than pure science. Mr Barber's razor may do some of Lord Rothschild's work.

100 years ago

NATURE

THE POLLUTION OF RIVERS

The question which has to be settled is not whether anything is to be done to remedy the certainly disgraceful state of some of our streams, but rather to what extent can the purification be pushed without detriment to the industry of the district; and when this has been decided comes the next question, how this partial purification is to be effected. That it can only be a partial purification is clear from the conclusions of the Commissioners themselves, who do not propose any plan by which the water of our rivers, in populous districts at present little better than sewers, shall be so purified as to be fit for drinking purposes.

Energy planning Soviet style

by our Soviet correspondent

ENERGY has been an emotive concept in the Soviet Union since 1920, when the Eighth All-Russian Congress of Soviets adopted the "Goelro" plan for the electrification of the country, with Lenin's famous equation "Communism =Soviet Power+Electrification". It was a coal miner called Stakhanov who, in 1935, by mining fourteen times the normal output of one man in a single shift, became the eponymous hero of the concept of 'Stakhanovite' labour. New prestige projects, such as the Bratsk power station or the Novopolotsk oil refinery, remain standard subjects for poets of a high literary reputation—and their works are analysed by the critics with more than usual attention to their political content. Yet the very significance of energy as a touch-stone of Soviet progress makes it somewhat difficult to assess the overall situation. When the opening of each new power station is reported by the press in careful detail, and with the Soviet propensity for presenting statistics not in absolute figures, but as percentages relative to some inaccessible base year, it is easy to become lost in a mass of minutiae on the one hand and of vague generalities on the other.

Conversely, it is not always easy to distinguish the economically viable project from that undertaken primarily for prestige purposes. Thus the plan described in an *Izvestiya* interview in January 1971 by Minister of Electrification Petr Neporozhnyi, which involved the use of power stations on the White Sea to fill in at peak consumption periods, loses a certain amount of its credibility when one remembers that they would be inoperable during the winter months—at precisely the time when the new unified grid has to depend almost entirely on thermal generation since the Siberian hydroelectric stations are also icebound. On the other hand, the imaginative proposals of I. V. Shishkin for running an entire city on thermal waters would seem to be economically viable, given his basic assumptions of a stratum temperature of 150° C and a sufficient water table (*Priroda*, No. 5, 95–103; 1969).

The present power difficulties of the western nations, however, have evoked considerable comment in the Soviet press from which the picture does become a little clearer. Side by side with cartoons of the pathetic British motorist walking his car to work emerge more factual statements, such as an interview (*Novoe Vremya*, No. 48, 20–22; 1973) with Ruben Napoleonovich Andreasyan, a senior researcher at the Institute of World Economics and International Relations. Andreasyan categorically denied Western reports of an oil shortage in the Soviet Union and was prepared to quote figures. The Soviet Union, he stated, "is one of the richest countries in the world as regards resources of liquid fuel. . . It should be said that the oil of Western Siberia is outstanding not only on account of its high quality, but also its low cost. . . The Soviet Union is already one of the largest oil exporters in the world. In 1972, it exported 76.2 million tonnes of crude oil, not counting prepared petroleum products". As to the reports that the Soviet Union imports Arab oil, this is true, but the amount involved is only 7.8 million tonnes, ten times less than the export figure, and is intended as a gesture of aid to the balance of payments of the oil exporting countries. Of the oil exported, some 50 million tonnes goes to the non-Communist world, and the rest to the Comecon bloc through the "Druzhba" pipeline system, which celebrated its tenth anniversary on December 23, 1973. Reports of the economic integration of Comecon would suggest that by now the smaller member countries supplement their domestic oil production (if any) entirely from Soviet sources, but Reuter reports from Warsaw early in the current crisis (November 25) revealed that Poland, at least, still buys a significant amount of her oil on the world market and has now introduced a speed limit of 80 kilometres an hour and similar measures for saving fuel.

Soviet oil production figures for January to November 1973 (*Pravda*, December 11, 1973) totalled some 385,000 million tonnes (25 million tonnes more than for the same period in 1972), together with some 46,000 cubic metres of natural and petroleum gas. The pride of the Soviet oil industry, the West Siberian (Tyumen') oil field (opened up in 1964), has already surpassed its target for the current year by some 2.3 million tonnes and is expected to produce 87.5 million tonnes in all—some 3 million tonnes above the target. According to a Tass report headlined by the Minsk newspaper *Zviazda*, the Tyumen' field has achieved a record output of 285,000 tonnes in 24 hours.

Nevertheless, the budget and state plan for 1974 (*Pravda*, December 13, 1973) places great stress on "the fuel and energy sectors". The output of electrical power is assigned a target of 975,000 million kilowatt hours (kWh)—an increase of 6.6% in comparison with 1973. The output from nuclear power stations is to be increased to 161,000 million kWh (38% more than in 1973). This increase in electrical output will permit industry to increase its consumption by 5.7%, agriculture by 13% and "the community and living needs of the urban population" by 8%.

The following increases in fossil fuel outputs are envisaged: petroleum and gas condensates by 30 million tonnes (7%), gas by 20.8 million cubic metres (1.8%), mainly from West Siberia, the Kazakh SSR, Central Asia, the Komi ASSR, the Udmurt ASSR and the Perm' and Orenburg regions. To serve these fields, more than 9,000 km of new pipeline and 85 pumping and compressor stations are scheduled to go into service during 1974. The oil refining and petrochemical industries are assigned an increased target of 6.8% with a "considerable increase" in the output of high-octane and low-sulphur fuels. A mouthwatering picture to the harassed Western consumer, perhaps—yet it must be recalled that one has no clear picture of the potential demand, and plans for such large increases may be evidence of the need to close even greater gaps.

Coal output is planned to be 679.1 million tonnes—10 million tonnes more than 1973, with 8 million tonnes of the increase coming from open-cast mining. This emphasis on open-cast mining became evident in the late 1950s with the opening up of new coalfields in northern Kazakhstan and central Siberia.

These figures, it is stated, should basically cover all "normal regular demands". Nevertheless, "it is necessary to exhibit care in expending fuel resources, and to ensure the unconditional fulfilment of the plans for saving fuel and electricity"; this is another indication, perhaps, that demand still outstrips supply.

Geothermal energy in California

Colin Norman, Washington

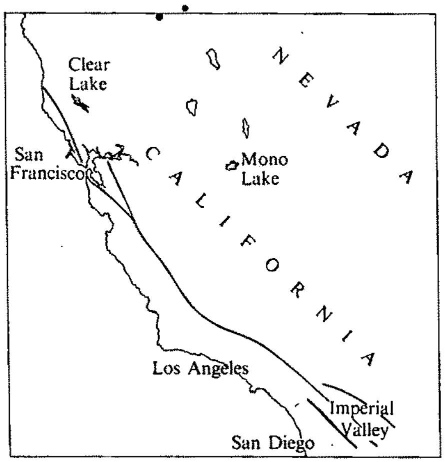
LATER this month the US Department of the Interior will take a large step towards opening up a new source of energy in the United States. On January 22 some 50,000 acres of federal land in California will be leased to private industry so that a start can be made on producing electricity from steam and superheated water trapped in deposits relatively close to the surface. Such deposits of geothermal energy have long been touted as potential sources of power, and the energy crisis has provided the necessary incentive for the federal government to set aside environmental and other concerns and open up large areas of the western United States for drilling to tap the resources.

The potential impact of geothermal energy on power supplies in the United States is a matter of some debate, for estimates range from 1% of energy supplies by the year 2000 to a staggering 20%. A report put together by the University of Alaska under the direction of Walter J. Hickel, former Secretary of the Interior, came up with the prediction earlier this year, for example, that geothermal energy could provide 1,000 million megawatt hours (MWh) of electricity by 1985, and 3,100 million MWh by the end of the century—more than five times the present power demand of the whole of New England. The Department of the Interior, on the other hand, reckons that by the year 2000, geothermal energy may be supplying a modest (but important) 2% of the United States national electricity generating capacity.

In any case, commercially exploitable geothermal resources are regions where the great heat of the Earth's interior is close to the surface. Essentially, that means along the edges of plates and near recent volcanic formations. Since two plates meet at the San Andreas fault in California, and since much of the Western United States consists of volcanic rocks, the potential geothermal resources could be large.

The idea behind production of electricity from geothermal resources is simple enough—in fact, a geothermal power plant has been operating at Larderello in Italy since 1904 and another plant has recently been built in northern California. The easiest deposits to exploit are entrapments of hot, dry steam, which can be tapped simply by sinking a pipe into the deposit and using the steam directly to drive turbines. Deposits of superheated water at about 200° C are also relatively easy to tap, since the water can be flashed to steam by relieving some of the pressure.

Unfortunately, however, such deposits are relatively few and far between, and geothermal energy will have a large impact on power supplies only if methods can be found for exploiting cooler water deposits and hot rock reservoirs. As far as the former is concerned, it may be possible to transfer heat from the water to a more volatile liquid and use the vapour from the second liquid to drive a turbine in a closed system. Hot rock reservoirs are by far the most abundant geothermal resources but they are also the most difficult to exploit. Research is under way on methods which involve fracturing the rock underground with explosives and circulating a liquid through the fractured rock to pick up some of the heat. But commercial application of such techniques is considered to be a long way off.



Map showing locations of areas to be leased.

The areas which the Department of the Interior will lease this month all contain steam and superheated water deposits and thus can be used to generate electricity fairly quickly. Three areas will be leased. One, the Clear Lake–Geysers area in northern California, is already producing some 400 MW of electricity and is reckoned to be capable of producing between 1,000 and 5,000 MW. The second area is in the Mono Lake–Long Valley region east of San Francisco; this is expected to produce about 1,750 MW. And the third area is the Imperial Valley, in southern California, along the Mexican border. This field has the largest potential, for it has been estimated that it could produce between 3,000 and 30,000 MW of electricity, and it also lies close to Los Angeles and other large urban centres.

In addition to opening up those areas for geothermal power production, the Department of the Interior has announced that it will accept bids from private industry for other federal lands which may be potential geothermal resource areas. This should stimulate the search for other areas of geothermal energy which can be easily exploited. And, for the longer term, the federal government is preparing to step up spending on research and development on production of power from less accessible geothermal resources. The five-year plan put together by Dr Dixie Lee Ray, Chairman of the Atomic Energy Commission, envisages an expenditure of some $185 million before 1980, for example.

Agreement on budget for HEW

Colin Norman, Washington

CONGRESS and the Administration have at last managed to reach agreement on the size of the budget for the Department of Health, Education and Welfare (HEW). The agreement will give the research institutes of the National Institutes of Health at least $1,723 million this fiscal year—nearly $200 million more than the Administration had wanted to spend. A number of recent court decisions have also sharply reduced the Administration's ability to hold back money appropriated by Congress and thus it seems unlikely that the Administration will be able to follow its usual tactics of simply refusing to spend extra money voted by Congress.

The compromise budget was passed by Congress early last month and it was signed into law by President Nixon just before Christmas. The fact that a budget has at least been agreed upon is a landmark, for HEW has been operating for more than 18 months on a complicated budgetary formula because Congress and the Administration have repeatedly failed to see eye to eye on spending priorities. Last year, President Nixon vetoed two HEW appropriations bills passed by Congress because he considered them to be inflationary and this year he threatened to veto an earlier version of the bill for the same reason.

Congress has now worked out a formula for the HEW budget which President Nixon still believes to be excessive but which he found politically acceptable. Essentially, Congress added some $1,100 million to the Administration's budget request but it has also given President Nixon power to withhold up to $400 million of the appropriate funds. An important aspect of the bill is that Nixon can lop no more than 5% off the funds allocated to any given programme. Thus congressionally determined priorities cannot be upset by the White House.

As far as the National Institutes of Health are concerned, even assuming that President Nixon exercises his authority to reduce the total HEW budget by $400 million (as he almost certainly will), every institute is set for at least a moderate budget increase. The National Cancer Institute will get $523.6 million—an increase of $23.6 million over the Administration's budget request—and the National Heart and Lung Institute will receive $287.8 million. The largest increase, however, will go to the National Institute of General Medical Sciences, which is set to receive at least $167.9 million; the Administration had wanted to spend only $138.5 million. The National Institute of General Medical Sciences is primarily responsible for supporting basic research and Congress decided to give it a considerable increase after a string of influential scientists had complained that the crusades against cancer and heart and lung diseases were taking money away from important areas of basic research.

Research cuts irksome but tolerable

John Hall

ALTHOUGH cuts in British government spending will cause reductions of more than £8 million (5.5%) in research council budgets for next year, there is a feeling that the economies required are irksome rather than seriously debilitating for the five councils involved.

The Department of Education and Science, which was to have spent £151.6 million (at 1973 values) on research and postgraduate training through the research councils during 1974–75, has issued a revised estimate of £143.5 million, following the chancellor's power crisis budget of December 17, when an overall reduction in public spending of £1,200 million was announced.

The Science Research Council (SRC), which was to have received £72.4 million, will now be given £2.6 million less; the Medical Research Council (MRC), due to have received £29.5 million, loses £1.3 million; the Agricultural Research Council's £23.9 million is cut by £1.4 million; the Natural Environment Research Council (NERC) loses £1 million from its projected £19.5 million; and the Social Science Research Council drops £1.8 million from a proposed £6.5 million.

The NERC is postponing work on two capital expenditure programmes (the Institute for Marine Environmental Research at Plymouth and the British Antarctic Survey building at Cambridge) but otherwise the councils are talking in terms of careful, across the board economies rather than of halting projects which are already under way.

The Agricultural Research Council gave an assurance that salaries and wages of existing staff would not be affected by the 16.3% cut it has to make. The reduction will be spread almost equally across capital and current expenditures, and the effect of the budget changes on individual research units has yet to be determined.

The NERC's saving will be of £600,000 on current and £400,000 on capital spending, and will be achieved by a process of "slowing things down rather than actually cutting anything out".

An MRC spokesman's comment on the cuts was that £1.3 million might look like a lot of money but spread across its own 80 research establishments, and other users, it did not exactly amount to a crippling threat. In the same vein the SSRC promised that "such a small amount" could be saved by marginal reductions in the funds that were made available for new commitments in research and postgraduate training.

The SRC was keeping quiet about the cuts until its members could meet for discussions.

Knights Bachelor

IN the New Year Honours List the following have been created Knights Bachelor:

Stanley George Hooker, Group Technical Director of Rolls-Royce (1971) Ltd;

Maurice George Kendall, for services to the theory of statistics;

John Cowdery Kendrew, for services to the Ministry of Defence;

Charles William Oatley, Emeritus Professor of Electrical Engineering, Cambridge University;

Hugh Norwood Robson, Vice-Chancellor, Sheffield University;

Frederick Henry Stewart, Regius Professor of Geology, Edinburgh University.

Ethiopian Calamity

SIR,—In the article 'The Ethiopian Calamity' (*Nature*, **246**, 53; 1973) your correspondent writes that a plea went to the World Food Programme but that "aid did not materialise from this source for several months".

After almost 11 years of food aid activities during which time this Programme has shipped some four million tons of food aid for social and economic development and emergencies, we have not found it possible to procure and deliver large quantities of food from ports in North America or Western Europe to developing regions in a matter of days or even weeks. This difficulty was fully appreciated by the Government of Ethiopia which, in its request to WFP for 20,000 tons of grain in April this year, asked for delivery by December 1973. Supplies are now arriving as planned. However, because of assurances of the arrival of WFP food, the Government was able to borrow from its national stocks and began distribution in May. The WFP food now arriving will be used to replenish these stocks.

Meanwhile, the Programme has arranged for shipment of a further 15,000 tons of grains plus an additional $350,000 for internal transportation of relief supplies regardless of their source. This will bring WFP's total contribution to 25,000 tons of food grains and $550,000 in cash.

Yours faithfully,

FRANCISCO AQUINO

Executive Director,
World Food Programme,
Via delle Terme di Caracalla,
00100–*Rome*

Fortuitous Correlations?

SIR,—The article 'What's in a Name?' (*Nature*, **246**, 385; 1973) pointed out a number of significant correlations but ignored the rich contributions made by brain research workers to this field[1–4].

Yours faithfully,

G. CURZON

Institute of Neurology,
Queen Square,
London WC1N 3BG

news and views

Narcotic action at the molecular level

Opium and its derivatives have been used for centuries to ease the pain of injury and illness, and to blur the mental anguish of society's less fortunate. Morphine, the primary active ingredient of opium, has long been the standard analgetic. Morphine's medical usage, however, is constrained by the body's tolerance to opiates. Ever increasing dosage is required to maintain the analgetic effect. With chronic usage the body becomes dependent on the presence of opiate, and withdrawal causes agony.

For several decades scientists have sought a morphine analogue which would produce analgesia without tolerance (see Eddy and May's review in *Science*, **181**, 407; 1973). Attempts to elucidate the mechanism of opiate action have been spurred on by the epidemic of heroin (diacetylmorphine) abuse which has became a socio-medical problem of staggering proportions in most western cities.

Last spring Pert and Snyder announced their biochemical demonstration of a receptor in nervous tissue which binds opiates with stereospecific selectivity and with affinity paralleling pharmacological potency (*Science*, **179**, 1011; 1973). In the ensuing months a stream of reports from Snyder's laboratory has demonstrated the utility of their assay, both for studying the basic pharmacology of opiate action and for rapid screening of narcotics with medical potential.

In *Nature* on October 26, Kuhar, Pert and Snyder (**245**, 447; 1973) described detailed mapping of the concentration of opiate binding sites in both human and monkey brains. They discovered striking regional variation in binding, with receptor concentrations varying more than thirty-fold between the highest and the lowest areas. Interestingly, the regions high in opiate binding all lie within the limbic system. Binding is greatest within the anterior amygdala, uniformly high throughout the hypothalamus, and high in medial but not in lateral thalamus. Frontal cortex areas show moderate binding of opiate, but little is found elsewhere in the cerebrum. This distribution leads to intriguing speculation about how the analgetic and euphoric effects of opiates might be related to limbic involvement in perception and expression of emotion and in the direction of motivated behaviour.

How well does the density of opiate binding sites correspond to the locations at which externally administered narcotics affect the brain? Previous workers have inserted morphine into various brain regions of living animals and tested for analgetic response; the distributions of opiate binding and of pharmacological effect seem well correlated.

There has been considerable controversy over whether opiate action is associated with some particular neurotransmitter. From the evidence various proponents have presented, one may conclude that the target of opiates is serotoninergic, or noradrenergic, or perhaps cholinergic. In this study, Snyder's group asked whether opiate binding could be correlated with distributions of acetylcholine, catecholamines, GABA or serotonin. Disappointingly, although there were some similarities, there was no clear-cut parallel in any case. Furthermore, lesions of well known nerve tracts specific for acetylcholine, noradrenaline, or serotonin produced no change in opiate binding in the affected areas.

Much narcotic research has centred on searches for the basis of the contrasting actions of opiate agonists and opiate antagonists. Many modifications of the morphine chemical structure have been studied in search of an analogue with a more amenable spectrum of pharmacological activity. In the process of searching, there were discovered certain analogues which block completely the action of opiate agonists (structures with morphine-like action). These 'antagonists' do not cause dependency, and in fact dramatically precipitate withdrawal in morphine-dependent animals. Safe, long lasting opiate antagonists are avidly being sought, with the idea of 'treating' addicts by thwarting the effect of heroin consumption.

Pert and Snyder have recently shown that the various opiate agonists and antagonists have a wide range of binding affinities for nervous tissue, and that there is a high correlation between affinity and pharmacological efficacy of these drugs *in vivo* (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2243; 1973). Agonists and antagonists apparently compete for the same receptors, and because there is complete overlap in the range of affinities of the two classes of opiate, it would seem that the difference in their pharmacological effect must lie in some difference in cellular response ('intrinsic action') due to contrasting structure. Pert, Pasternak and Snyder have now discovered a difference in the way agonists and antagonists are bound by brain tissue, and that this differential effect can be used to discriminate *in vitro* between the two classes of opiate (*Science*, **182**, 1359; 1973). They first found that injection of mice with either opiate agonists or antagonists produced within minutes a significant increase in the number of opiate binding sites. The narcotic antagonists were 10 to 1,000 times more potent than structurally related agonists in enhancing receptor binding, which corresponds well to the fact that antagonists affect the body at much lower concentrations than do agonists.

In the light of the far greater pharmacological potency of narcotic antagonists, it seemed puzzling that agonists, such as morphine, oxymorphine and levorphanol, showed *in vitro* binding affinities quite similar to those of the structurally corresponding antagonist derivatives nalorphine, naloxone and levallorphan (respectively). This puzzle was resolved by the propitious discovery that adding sodium to the assay medium (in concentrations corresponding to those found in the body) considerably increased antagonist binding, while lowering that of agonists. Interestingly, the increase in binding is caused not by a change in receptor affinity but by an increase in the number of receptor sites available.

The discovery of this differential ionic effect on binding offers the prospect of a simple biochemical test for discriminating the agonist and antagonist activities of drugs which might be used for treatment of heroin addiction or which might provide analgesia without physical dependency. The authors examined the ability of a series of known opiate agonists and antagonists to inhibit the binding of tritium-labelled naloxone (an antagonist), both in conditions of low sodium and of high sodium. High sodium did not alter the binding of antagonists, but drastically lowered the ability of agonists to compete for receptor sites. Pentazocine, which has a mixture of agonist and antagonist properties, showed an intermediate loss of binding. Such mixed action drugs are clinically important because they offer the possibility of 'non-addicting' analgesia. It is theorised that the ability to block pain is a function of agonist affinity, and that addiction is prevented when agonist and antagonist actions are present simultaneously.

Histone mRNA and maternal message

from a Correspondent

HISTONE mRNA not surprisingly may be isolated from many cell types as a 7–9S component which resolves on acrylamide gels into six or seven bands (Weinberg *et al.*, *Nature*, **240**, 225; 1972). Until recently the evidence in favour of these RNAs being truly histone messages was circumstantial, but Jacobs-Lorena, Baglioni and Borum (*Proc. natn. Acad. Sci. U.S.A.*, **69**, 2095; 1972) have provided proof that a 7–9S RNA species is translated into histones in an ascites cell free system. The original work of Robbins and Borun (*Proc. natn. Acad. Sci. U.S.A.*, **57**, 409; 1967) showed that in HeLa cells histones are synthesised during S phase on small cytoplasmic polyribosomes and this led to the identification of a rapidly labelled 9S RNA species associated with them (Borun, Scharff and Robins, *Proc. natn. Acad. Sci. U.S.A.*, **58**, 1977; 1967).

Early work by Kedes and Gross on sea urchin embryos (*Nature*, **223**, 1335; 1969; and *J. molec. Biol.*, **42**, 559; 1969) confirmed the existence of a newly synthesised 9S RNA species associated with small polysomes during the phase of rapid cell division called cleavage at the start of development. The system was notable for the very high specific activity to which the 9S RNA could be labelled, for the apparent ease of 9S RNA purification and for its freedom from contamination by labelled ribosomal RNA, which is not synthesised in appreciable quantities until much later. It is not difficult to think of things to do with highly labelled mRNAs even though they lack authentic credentials and, first, Kedes and Birnstiel (*Nature new Biol.*, **230**, 165; 1971), in what they regarded as the first steps to the isolation of a eukaryotic gene coding for a specific protein, produced evidence for reiterated, closely clustered histone coding sequences potentially separable from the rest of the genome.

Weinberg, Birnstiel, Purdom and Williamson (*Nature*, **240**, 225; 1972) took this analysis further by showing that component species separable from 9S histone messages each hybridise to DNA sequences several hundred times repetitive. The different groups of repetitive histone DNA seem to be closely linked since hybridisation of the RNA subfractions to DNA banded in CsCl shows that they all fall in the same region at a density (1.705 g cc^{-1}) just greater than the main band (1.697 g cc^{-1}).

In spite of the fact that histone 9S mRNA synthesis starts soon after fertilisation in sea urchins, treatment with actinomycin D at concentrations which inhibit synthesis permits many cleavages and apparently normal development to the blastula stage (Gross and Cousineau, *Exptl cell Res.*, **37**, 368; 1964). Embryos thus treated continue to synthesise proteins though not nuclear proteins during this time (Raff, Greenhouse, Gross and Gross, *J. cell Biol.*, **50**, 520 ; 1971) and this was regarded as indirect evidence for the absence of stored histone message in unfertilised eggs.

Two recent papers from Gross and his colleagues now provide direct proof that histone mRNA on the contrary is stored in unfertilised sea urchin eggs although at a lower level than that attained during cleavage, and this constitutes the first demonstration of a maternally-inherited message with a defined coding sequence. Many previous attempts have been made to provide direct evidence for stored maternal mRNA in echinoderm (Slater and Spiegelman, *Proc. natn. Acad. Sci., U.S.A.*, **56**, 164; 1966) and *Xenopus* (Davidson, Crippa, Kramer and Mirsky, *ibid.*, **66**, 379; 1972) embryos, but in none of these cases was an identifiable maternal RNA species shown to stimulate the synthesis of a defined product.

What Gross *et al.* (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2614; 1973) did was to extract RNA from different regions of a sucrose gradient in which a post mitochondrial supernatant from homogenised unfertilised echinoderm eggs had been centrifuged such that the 80S ribosomes were almost pelleted. They found that a mouse ascites cell free system will make protein from these RNA preparations but that the most active fractions are from the ribosome subunit region of the gradient (20–40S). Using aspartic acid and lysine to show up differences in mRNA coding sequence they found that the faster sedimenting RNP fractions give RNA which incorporates more aspartic acid relative to lysine than the more slowly sedimenting fractions. By running the labelled products in acrylamide gels together with authenic labelled histone, and by analysing tryptic peptides, they were able to show that the RNA from a slowly sedimenting (20S) RNP fraction makes histone protein almost exclusively and that the more rapidly an RNP sediments beyond 20S the less histone protein will be made by its RNA. These experiments show that mRNAs exist in non-ribosome bound RNP particles from unfertilised sea urchin eggs and that they are capable of stimulating the synthesis of histone in a cell free protein synthesising system.

Skoultchi and Gross (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2840; 1973), using the completely different approach of competition-hybridisation to detect specific mRNA sequences, have been able to provide direct support for the conclusions drawn from *in vitro* protein synthesis studies. They used ^{3}H-labelled 9S RNA from sea urchin embryos in conditions in which most of the input labelled RNA can form hybrids with DNA but which still allows identical unlabelled RNA to compete for sites. Both total RNA from small polysomes and unfertilised eggs competed in the reactions but purified 18 and 26S ribosomal RNA, rabbit globin mRNA and 9S histone mRNA from another echinoderm species did not. The curves generated suggest that the amount of histone mRNA in unfertilised eggs is one-quarter of that in the small polysomes of an embryo of 100 cells. This figure is in agreement with similar work by Farquhar and McCarthy (*Biochem. biophys. Res. Comm.*, **53**, 515; 1973), who used very different conditions for their hybridisation.

Skoultchi and Gross went on to show that RNA from subribosomal RNP particles from unfertilised eggs competes with 9S histone mRNA in agreement with the prediction from the protein synthesis studies of Gross *et al.* These papers represent a real advance since they unequivocally identify by two very different methods a messenger RNA which is maternally inherited.

Role of plastocyanin in photosynthesis

from our Photosynthesis Correspondent

THE old argument whether or not plastocyanin acts between cytochrome *f* and the reaction centre of photosystem 1 (P700) now seems to be over. It has been known for many years that this copper containing protein is an important component of the photosynthetic electron transport chain but there have been several contradictory hypotheses about its exact site of action. The most widely accepted view is that plastocyanin acts as an intermediate between cyt *f* and P700. Not all investigators, however, agree with this scheme and prefer to place plastocyanin on the oxidising side of cyt *f* so that cyt *f* acts as the primary electron donor to P700. Alternative suggestions have been that plastocyanin and cyt *f* act in parallel in such a way that they both donate electrons to P700 or that they are associated with the different photosystems; plastocyanin with photosystem 2 and cyt *f* with photosystem 1.

It now seems from a recent publication from San Pietro's laboratory at Indiana (Siedow, Curtis and San Pietro, *Arch. Biochem. Biophys.*, **158**, 889; 1973) that the most popular hypothesis is correct. In a very careful piece of work Siedow *et al.* have demonstrated that plastocyanin acts stoichiometrically as an electron carrier between cyt *f* and P700. Their work is particularly convincing because they have managed to prepare subchloroplast particles which are completely depleted of plastocyanin. These particles were obtained by sonicating osmotically shocked chloroplasts suspended in a medium containing a low concentration of pyridine. Using difference absorption spectroscopy Siedow *et al.* have demonstrated that these particles were unable to support the photo-oxidation of cyt *f* until plastocyanin was added to the suspension. Moreover, they found that it was necessary to either treat the particles with non-ionic detergents such as digitonin or sonicate them after adding the plastocyanin to induce full photo-oxidation of the cytochrome.

The results of these experiments clearly support a strict linear sequence of electron transport on the oxidising side of photosystem 1 from cyt *f*→ plastocyanin→P700. Furthermore, the requirement for sonication or detergent treatment to bring about the full reconstitution supports a concept already put forward by Hauska *et al.* (*J. biol. Chem.*, **246**, 189; 1971) that plastocyanin, *in situ*, binds to a specific site on the inner surface of the chloroplast membrane.

Structural analysis by electron diffraction

from a Correspondent

A JOINT meeting of the Crystallography and Electron Microscopy Groups of the Institute of Physics was held at the Institute of Electrical Engineers, London, on November 15–16 to discuss the use of electron diffraction for structure determination. The contributions covered electron diffraction from gases and surfaces, structural analysis of thin films by combined electron diffraction and microscopy, direct lattice resolution by electron microscopy, as well as applications of these techniques to the study of molecular crystals and minerals. There was also a discussion of the interpretation of electron micrographs and diffraction patterns of amorphous materials.

Gases and surfaces

D. W. J. Cruickshank (UMIST, Manchester) opened the meeting with a review of electron diffraction from gases. Since the 1930s some twenty groups around the world have analysed between them more than 1,000 molecules. The techniques and methods of interpretation are by now fairly standard and the interest lies in the chemistry of the molecules themselves. It is particularly interesting to compare rather similar molecules and to find surprises—for example, $(SiH_3)_3N$ is a planar molecule whereas $(SiH_3)_3P$ is pyramidal. Similarly, in the so-called 'sandwich' molecules $(C_6H_6)_2Cr$ and $(C_5H_5)_2Fe$, the metal atoms are symmetrically placed between the rings but in $(C_5H_5)_2Be$ the Be atom is asymmetrically placed and in $(C_3H_5)_2Ni$ there are two variants, in one of which the two carbon frameworks are not parallel.

M. Prutton (University of York) gave an account of the determination of surface structures by RHEED (reflection high energy electron diffraction) and LEED (low energy electron diffraction). Both of these methods are sensitive to the crystallography of the surface layers because of the low penetration of the electron beam and both can be used to obtain the mesh sizes of the surface and of adsorbed layers. The use of quantitative intensity data to deduce the position of atoms in the unit mesh has, however, proved more difficult. In the case of RHEED, transmission diffraction through asperities presents an experimental problem and surfaces with small roughness on the 10 Å scale are needed. For LEED, although progress in the theory has been rapid recently, Prutton felt that it was still extremely difficult to make good quantitative statements. This point was (perhaps inadvertently) reinforced by M. A. van Hove (University of Cambridge), who indicated that in the case of oxygen adsorbed on (100) Ni in a c(2×2) structure, the oxygen atom has been deduced by different workers to be either 1.5 ± 0.1 Å or 0.9 ± 0.1 Å above the Ni atoms, with an almost equally good fit to theory in both cases, but that values in between were impossible on the basis of a match between dynamical LEED theory and experiment. Of the two possible values the first is much more plausible from a chemical viewpoint.

The information obtainable from an understanding of the dynamical transmission diffraction effects through thin films was reviewed by J. W. Steeds (University of Bristol). Of the two techniques considered, the convergent beam technique and the analysis of electron microscope images of bent crystals, it is the second which is easier to use for qualitative crystal structure determination. Steeds showed that one could easily use the form of bend contours to deduce the point group of the crystal and that dark-field observation could establish the presence of centres of symmetry, glide planes and screw axes, which could lead to the establishment of the space group. Applications to layer structures such as mica and molybdenite were described in this and in the following papers by G. J. Tatlock and Steeds. The simulation of these bend contours using many-beam dynamical theory yielded impressive agreement with the experimental contours, and enabled them to distinguish easily different polytypes of molybdenite and to detect the presence of otherwise invisible stacking faults.

Lattice images

J. Hutchison (University of Oxford) gave a fascinating glimpse into the future with his talk on direct lattice resolution by electron microscopy. In the past few years the electron microscope has been used to study the lattice images of several structures including a class of complex oxides called block structures based on NbO_6 octahedra. The octahedra are stacked together in blocks of, say, 4×3 or 5×3 and have tetrahedral sites at the corner, where four blocks join together, which can accommodate substitutional metal ions. In the extremely high resolution micrographs shown, the blocks and the positions of the heavy atoms in a compound such as $W_4Nb_{26}O_{77}$ were clearly seen, and the experimental images were in excellent agreement with simulated images based on *n*-beam dynamical theory; one can almost resolve the individual octahedra in both the experimental and simulated images. The images depend in detail on the defocus of the objective lens, however, so that it is essential to know the amount of defocus and include this in the calculations.

Quasi-amorphous films

The use of dynamical diffraction theory for transmission electron diffraction from single crystal films is well established and Hutchison and Steeds elegantly showed how well the theory works. By contrast, the best theory for describing the diffraction from quasi-amorphous films is not nearly so clear; this was the theme of a panel discussion between W. Cochran (University of Edinburgh), A. Howie (University of Cambridge) and M. V. Berry (University of Bristol) under the chairmanship of D. J. H. Cockayne (University of Oxford). The problem arises because there are many possible structures of quasi-amorphous solids (such as amorphous Si and Ge) which would give the same diffraction pattern. Can lattice imaging in the electron microscope be used to give extra information? Previous work by Rudee and Howie had suggested the existence of microcrystallites, some 15 Å in diameter, on the basis of groups of 'lattice' fringes observed using a particular part of the diffraction pattern to form the image. These small regions are, however, embedded inside a film of thickness ≃200 Å, so that they are certainly not isolated crystallites, and the interference with the regions above and below any such crystallites, as well as the degree of defocus, are important in determining the image. Cochran has performed simulations of the image of a random network model and considers that although the fringes are unlikely to be due to such a structure, they do not really require a microcrystallite model either. He showed that changes in defocus during the exposure could cause certain periodicities in the image to be enhanced. Berry was inclined to favour an approach based on simple image transfer theory which he claimed means that the fringes in the image were merely random noise, spatially filtered by the objective aperture; provided a relatively small segment of the diffraction ring is used to form the image, groups of fringes would be observed, essentially independent of the detailed structure of the sample. Thus it is clear that the unravelling of the detailed structure of these quasi-amorphous films remains a difficult problem which is far from solved, though it is certain that electron microscopy has a part to play in its resolution.

Molecular solids

The application of electron microscopy and diffraction to the study of molecular solids and minerals was the subject of the last session at the meeting. C. A. English (University of Sussex) reviewed the work on solid rare gases, O_2, N_2 and CO_2, which has been carried out largely at the University of Sussex. An electron microscope fitted with a liquid helium stage is used and single crystals can be produced by annealing the thin films obtained by vapour deposition at a pressure of a few torr. Among the examples he described were the determination of the structure of α-N_2, the measurement of the stacking fault energy of solid xenon, twinning in β-O_2 and radiation damage in solid O_2, N_2 and CO_2.

An elegant structure determination of a molecular solid, poly sulphur nitride, by electron diffraction, was described by M. Boudeulle and P. Michel (University of Lyon). Also, the complexities of graphite-halogen intercalation compounds, including structures with very long period order giving rise to the very beautiful diffraction patterns, shown by W. T. Eeles (UKAEA, Capenhurst), revealed that there is much to be learned about the bonding in all the molecular solids discussed. The advantages of combined use of electron microscopy and single crystal electron diffraction when the crystals are too small for single crystal X-ray work were well illustrated in all these contributions.

Minerals

This same theme was reinforced by P. E. Champness (University of Manchester) in her review of electron diffraction and microscopy as a means of characterising minerals. Analysis of the characteristic X rays by EMMA (combined electron microscopy and microprobe analysis) to obtain chemical information from regions as small as 1,000 Å in diameter is also invaluable. A particularly impressive example of the combined use of these techniques is the study of an igneous pyroxene containing lamellae around 0.1 μm thick spaced about 50 to 100 μm apart. In between the lamellae there are very fine precipitates with a precipitate free zone next to the lamellae. The orientation relationships of all the phases can be determined by electron diffraction. Analysis of the Ca/Si X-ray intensity ratio reveals that the lamellae are rich in calcium and the diffusion profile of the calcium content between adjacent lamellae can thus be determined. The fine precipitates can be imaged by lattice resolution of the 1.8 nm spacing and shown to be only one unit cell thick.

The conference clearly showed the range of opportunities offered by electron diffraction, particularly when it is used in combination with electron microscopy and other techniques such as X-ray analysis. The greater difficulty of interpretation *vis à vis* X-ray diffraction remains, but well-founded dynamical diffraction theory is being used with very considerable success for quantitative work on thin films with high energy electrons. At low energy, theoretical improvements are rapidly being made, but much remains to be done before the theory can be used with complete confidence. Direct structure determination by high resolution electron microscopy is now a fascinating possibility and will undoubtedly be explored further in the future.

If M haemoglobin, then R or T?

from a Correspondent

Much ingenuity has been shown in utilising the structural differences found in the genetically determined haemoglobin variants to assist the study of the relationships between structure and function of normal haemoglobin. A striking example of this approach is the work of Mayer, Ogawa, Shulman and Gersonde (*J. molec. Biol.*, **80**, 187; 1973) on high-resolution proton nuclear magnetic resonance (NMR) spectral studies of the quaternary state of haemoglobin M(Iwate).

Hb-M(Iwate) is an α-chain variant (α^{87}His→Tyr, β_2) and is identical with Hb-M(Oldenburg) and Hb-M(Kanakee). Apart from shortening the list of M-type haemoglobins, the locations in which it has been discovered provide an interesting example of the probable independent occurrence of the same mutation in three widely separated places. As with other M-type haemoglobins the chemical properties of the haems on the variant chains are abnormal. It has previously been shown that in the crystal the quaternary state is deoxy (T) when the normal β-chain subunits are deoxygenated and also when they are oxidised to methaemoglobin and therefore ligated with H_2O. In view of the low oxygen affinity of the variant it seemed probable that after ligation it remains in the T quaternary structure in solution as well as in the crystal. Mayer and colleagues have therefore used Hb-M(Iwate) to test the extent to which three NMR spectral features are linked to the state of the quaternary structure.

These three features are (1) the paramagnetically-shifted resonances of the cyanide-liganded subunits in valency-hybrid haemoglobin, (2) the upfield resonance in oxy and carbonmonoxyhaemoglobin assigned to Val E11 near the haem group, and (3) the low-field resonance near −14 p.p.m. (referred to 2,2-dimethyl-2-silapentane-5-sulphonate) in deoxyhaemoglobin which comes from an exchangeable proton, and which disappears on ligation. Although these three features had been used to distinguish between oxy (R) and deoxy (T) quaternary structures, their validity had not been tested with a haemoglobin known to be in the T quaternary state in solution even when ligated.

A comparison of the 220 MHz NMR spectra of normal human adult haemoglobin valency hybrids and of Hb-M (Iwate) in the presence and absence of organic phosphates clearly shows that those NMR spectral features previously attributed to the deoxy (T) quaternary structure are present in Hb-M(Iwate) when the β subunits are ligated to O_2, CO or CN^- as well as when they are unligated, with the quaternary structure remaining in the deoxy (T) state throughout. These results complement previous spectral studies on Hb-Kansas ($\alpha_2\beta_2$ 102 Asn→Thr) and on valency-hybrid haemoglobin.

In the authors' view, the increasing body of evidence that the quaternary structure is the most important factor in determining the functional properties of haemoglobin provides additional support for a two-state model, as proposed by Monod, Wyman and Changeux in 1965, as a suitable first-order description of haemoglobin function.

In another application of NMR spectroscopy to the study of haemoglobin, Manuck, Maloney and Sykes (*ibid.*, 199) have studied the binding of methyl *iso*nitrile to the β chains by measuring the transverse relaxation times (T_2) of the *iso*nitrile protons as a function of protein concentration, temperature and ^{14}N decoupling. Binding both at the haem iron and at non-specific site(s) affects the measured relaxation times. From the results a value of 57 ± 12 s^{-1} for the 'off' rate constant (k_{-1}) for specific binding, and an Arrhenius activation energy for k_{-1} of 14 ± 3 kcal mol^{-1}, were obtained.

Erasmus Darwin, master of many crafts

Desmond King-Hele

Royal Aircraft Establishment, Farnborough, Hampshire

Erasmus Darwin was famous in the eighteenth century as a physician, an inventor and a best-selling poet. Today he earns most credit for recognising biological evolution, discovering how clouds form, analysing plant nutrition and influencing the English Romantic poets.

DR ERASMUS DARWIN, who lived from 1731 until 1802, achieved more in a greater variety of intellectual disciplines than anyone since. Why then has he not gained the fame he deserves? Partly, perhaps, because we feel that his family already has enough fame, through his grandson Charles; and partly because of our unspoken but deep conviction that no one can really master many different crafts, as Darwin did. He belongs with Leonardo da Vinci and Goethe, immensely capable in practice and theory, in life, in literature and in science.

By profession Darwin was a physician, generally recognised as the finest doctor of his time in England. "Within the narrow resources of 18th-century medicine, he was supreme"[1], but he refused King George III's repeated requests to become royal physician[2]. By nature Darwin was a large and powerful-looking man (Fig. 1), cheerful and healthy, and, despite a stammer, a witty and rather domineering talker. By inclination he was extremely sociable and inventive. With Matthew Boulton and William Small, he founded the Lunar Society of Birmingham[3], which was the real intellectual driving force behind the Industrial Revolution in England and hence the modern technological world[4]. Encouraged by his Lunar friends, especially Watt and Wedgwood, Darwin produced working inventions ranging from a speaking machine to a horizontal windmill, and dozens of designs on paper, from a canal lift to a steam turbine. Darwin won greatest acclaim, however, in a quite different sphere, as a poet: his long poem *The Botanic Garden* took the literary world by storm in the early 1790s. Coleridge called him "the first *literary* character in Europe"[5], the Napoleon of literature, as it were.

Today Darwin earns most credit among scientists for his recognition of biological evolution[6,7], his psychological ideas[8], his analysis of plant nutrition and photosynthesis[9], and his discovery of the main process of cloud formation[10]. And the literary critics are ready to honour him not for his poems but for his immense influence over the English Romantic poets, Wordsworth[11,12], Coleridge[11-16], Shelley[11,17] and Keats[18,19].

Lichfield and the Lunar Society

Erasmus Darwin was born at Elston near Nottingham, the third son of a moderately successful lawyer. He went to Chesterfield School and from there to Cambridge, where he studied medicine and took his BA in 1754. Then came two years at the leading medical school, at Edinburgh. After this thorough schooling in dubious medical theory, he was ready to be loosed on the public. Finding no patients at Nottingham, he migrated to Lichfield, where he had the good fortune—or perhaps skill?—to cure a prominent local man whom all other doctors had condemned to death[20]. His future career assured by this *coup de théâtre*, Darwin settled at Lichfield. From 1758 until 1781, living in the pleasant house which still stands on Beacon Street at the western extremity of the Cathedral Close, he gave medical advice expensively to the rich and freely to the poor.

Today Lichfield is overshadowed by its neighbour Birmingham 10 miles to the south; but in the eighteenth century their roles were more nearly equal, and the Cathedral Close housed a literary coterie, headed by Canon Seward, the Dean, who edited the plays of Beaumont and Fletcher, as if to rival Lichfield's leading literary figure, Dr Johnson. As Darwin put it,

> From Lichfield famed two giant critics come,
> Tremble, ye poets! hear them! 'Fe, Fo, Fum!'
> By Seward's arm the mangled Beaumont bled,
> And Johnson grinds poor Shakespeare's bones for bread[22].

Canon Seward's daughter Anna, who was 14 when Darwin arrived at Lichfield, later became quite famous as a poet, with some help from Darwin: she was known as "the Swan of Lichfield" in insulting analogy with "the Swan of Avon".

In 1758 Darwin married Mary Howard, whose family also lived in the Close; the marriage proved a very happy one, marred only by Mary's continual ill-health. They had three sons who survived infancy. The eldest, Charles, was a brilliant medical student, but he died tragically at the age of 19 from an infection, after cutting his hand while dissecting. The second son, Erasmus, became a lawyer. The third, Robert, followed in his father's footsteps, becoming a successful doctor at Shrewsbury; he was an impressive man, not only in appearance (he weighed 24 stones) but also in ability, and especially in his uncanny power of reading character, much admired by his son Charles[23].

Erasmus Darwin was at his most inventive and socially active during the 1760s. One of his earliest friends was Matthew Boulton[24,25], then a humble manufacturer of buckles in nearby Birmingham. But his energy and enterprise were to make Boulton the chief manufacturer of England and "the father of Birmingham". Darwin's "favourite friend" in the late 1760s was the learned and liberal Dr William Small, recently returned from teaching in America, where Thomas Jefferson, one of his pupils, declared that Small's example "fixed the destinies of my life". About 1766 Darwin, Boulton and Small began those monthly meetings of friends at the time of the full Moon, which were soon to develop into what became known as the Lunar Society of Birmingham.

In the early days of his friendship with Boulton, in 1763, Darwin was madly enthusiastic about the idea of a steam carriage with twin cylinders, which he hoped Boulton would help him to construct. Boulton was rightly cautious, but Darwin's enthusiasm for steam was not wasted: James Watt on his first visit to England in 1767 called on Darwin[25,26] and began a lasting friendship, which benefited both. Watt was rather gloomy by nature and needed encouragement: who better to provide it than the energetic and optimistic steam-enthusiast Darwin? No wonder Watt, though usually reticent,

Fig. 1 Erasmus Darwin from a portrait-bust by William Coffee, reproduced by courtesy of Sir Robin Darwin.

praised Darwin so highly: "It will be my pride while I live that I have enjoyed the friendship of such a man"[27].

Another man who enjoyed that friendship to the full was Josiah Wedgwood[28], who met Darwin when both were about 30. When in 1765 Wedgwood and Brindley began promoting what was virtually a new transport system, the Trent-and-Mersey canal, Darwin was an enthusiastic supporter. Darwin's horizontal windmill was used for grinding colours at Wedgwood's factory for 14 years, until displaced by steam. The Darwin–Wedgwood alliance was strengthened by the marriage of Robert Darwin with Susannah Wedgwood in 1796.

One of Darwin's friends at Edinburgh had been the chemist James Keir[29], who after a spell in the Army settled at West Bromwich in 1768, and later set up an alkali factory at Tipton nearby. Keir was a pioneer of the chemical industry, and his clever process of obtaining soda from salt in dilute solution[30] was commercially successful many years before the Leblanc process was devised.

On his daily rounds as a doctor, Darwin was bumped and joggled over the vile roads in his carriage, so it is not surprising that he was keen to construct comfortable carriages. Wedgwood greatly admired a design which used the wheel spokes as springs (an idea continually being resuscitated, even today[31]) with each spoke shaped in the serpentine line of beauty. A carriage of Darwin's, peculiarly resistant to overturning, greatly impressed Richard Edgeworth[32], and inspired him to become an inventor. He visited Darwin in 1766 and became a lifelong friend.

This group of Darwin's friends—Boulton, Small, Watt, Wedgwood, Keir and Edgeworth—formed the nucleus of the early Lunar Society; Priestley was a later addition to their number. "Intellectually the most effective provincial group that has ever come together in England", C. D. Darlington has called them[6]. Individually they were among the most energetic and intellectually ablest men of the era, and their meetings, by some strange alchemy, channelled their talents fruitfully, producing a unique forward thrust in science and technology.

Middle and later life

During the 1760s Darwin's reputation as a doctor continued to grow, but he had no cure to offer his wife Mary, who died in 1770; her tributes to her husband were carefully recorded by Anna Seward[20]. In the 1770s Darwin remained at Lichfield, unmarried; but he had two illegitimate daughters, known as the Misses Parker.

Then in 1778 he fell in love with Mrs Elizabeth Pole, the lively, young and beautiful wife of a leading Derbyshire landowner, Colonel Sacheverel Pole of Radburn Hall. At first Darwin could only woo her in verse[20], but in 1780 Colonel Pole conveniently died and Darwin, though rather ugly, fat and fifty, brushed aside more eligible rivals and married Mrs Pole in 1781. They moved to Radburn and later to Derby. This second marriage proved as happy as the first, and the seven children of the marriage acknowledged their good fortune in having been brought up in such a happy atmosphere. This quiet happiness seems to have lasted throughout the 20 outwardly uneventful years of Darwin's second marriage[12]. He died in 1802 at the age of 70, of a heart attack.

A flowering of verse

Though outwardly unspectacular, these later years saw the publication of Darwin's five books, each epoch-making in its own way. First, in 1789–91, when he was already 60, came his encyclopaedic poem, *The Botanic Garden*, which gripped the literary world like a fever: "Dr Darwin has destroyed my admiration for any poetry but his own"[33], wrote Horace Walpole, a sentiment echoed by many another hard-boiled literary pundit. Part II of the poem, "The Loves of the Plants", had been published first, in 1789, because it was lighter—968 rhyming couplets about the sex life of plants, nicely personified and backed by masses of scientific notes. Part I, "The Economy of Vegetation", published in 1791, belies its title: it is really a compendium of scientific knowledge in 1,224 rhyming couplets, again with lengthy notes in support. The complete *Botanic Garden*, which was beautifully reprinted in facsimile by Scolar Press last year[34], runs to 550 quarto pages.

Was it wrong of those readers of the 1790s to admire *The Botanic Garden*? The poem is certainly rather rambling and unstructured; but Darwin's polished couplets have a lustre that time cannot tarnish, as generations of literary critics confirm (see, for example, refs 35 to 38). To this skill in verse Darwin added three other talents: 'a greater range of knowledge than any other man in Europe', as Coleridge put it[39]; originality in proposing new theories and foreseeing new technology; and an amazing lightness of touch—he is forever laughing at himself. As an example of all three talents, here is his forecast of mechanically-propelled cars and aircraft:

> Soon shall thy arm, Unconquer'd Steam! afar
> Drag the slow barge, or drive the rapid car;
> Or on wide-waving wings expanded bear
> The flying-chariot through the fields of air.
> Fair crews triumphant, leaning from above,
> Shall wave their fluttering kerchiefs as they move;
> Or warrior bands alarm the gaping crowd,
> And armies shrink beneath the shadowy cloud[40].

When Darwin switches from technology to plants in Part II, comedy is still in the ascendant as he promises to tell us

> What Beaux and Beauties crowd the gaudy groves,
> And woo and win their vegetable Loves.

For example in *Lychnis*, where the males and females are on different plants, each female saucily peeps out when mature:

> In gay undress displays her rival charms,
> And calls her wondering lovers to her arms[41].

Science so pleasantly presented was much to the taste of the leisured reading public. As L. T. C. Rolt has remarked, Darwin performed "the astonishing feat of rendering in imaginative terms which any literate man could then appreciate the sum of human knowledge at that time. It was an achievement which was never repeated or even attempted[42]".

Medicine, evolution, young ladies and plants

In his later years Darwin's fame as a doctor became excessive. With a lifetime's experience and few new discoveries to outdate it, he was a legendary figure, whose every word was eagerly sought—a status scarcely credible today when the mystique of the doctor has largely evaporated. Although his medical theory was unsound, Darwin deserved his fame as a doctor because he was so keenly observant and could often guess correctly the future course of an illness; his cheerful attitude and his sympathy with the patient also had a good effect. To this must be added his long and deep thought about medicine, expressed in the second of his books, the two massive volumes of his treatise on animal life, *Zoonomia*, published in 1794–96. Dr Beddoes called it "perhaps the most original work ever composed by mortal Man", which would "place the author amongst the greatest of mankind[43]". We do not value the book so highly today because its classification of diseases has too many flaws. But we can still admire some of his bold experimental cures, his linking of body and mind, which has been influential in philosophy[8,14], and his pioneer work in treating mental illness humanely instead of brutally. Whatever our reservations now, *Zoonomia* had great influence in its day: it went into a second edition in 1796 and a third (revised) edition in 1801; provoked a 560-page critical commentary in 1798; "was translated into German, French and Italian and was honoured by the Pope by being placed in the *Index Expurgatorius*", as Charles Darwin remarked[44].

Zoonomia is mainly medical, but it has one riveting chapter on biological evolution. As I have explained in a previous article in *Nature*[7], Erasmus appreciated and described the main mechanisms of evolution, and made it part of his habitual thinking for 20 years. In the England of the 1790s, reeling from the shock of the French Revolution, evolution was quite unacceptable: denying that God created species was near-treason; but Darwin was not sentenced to transportation, only to satire. In the *Anti-Jacobin* magazine in 1798 he was ruthlessly lampooned by Canning and others[45], while Coleridge condemned his evolutionary speculation as mere "Darwinizing".

Erasmus Darwin's correct advocacy of evolution does not detract from Charles Darwin's achievements. Rather it helps to explain Charles's success, by bringing out the strong tradition of evolutionary ideas in the family. For Charles's father Robert followed Erasmus in his profession and in his ideas (on alcohol and religion as well as evolution).

Erasmus carried his evolutionary ideas further than his grandson did, weaving it into his philosophy of life. Erasmus saw the full horror of the struggle for existence, more clearly than anyone else in his day, but he saw the bright side too. He believed most creatures delight in life; so, the better adapted they are, the happier they will be. Evolution is, in that sense, the survival of the happiest. Although highly organised animals have a greater capacity for happiness than lowly creatures, the plants and insects by their vast numbers make up a large part of the sum of happiness. This is the basis of his remarkable philosophy of organic happiness. He looks on rocks like limestone, chalk and coral, the remains of once-happy creatures, as "mighty monuments of past delight" and thinks we "should eye with tenderness all living forms". He is very much in favour of sexual love, not only because sexual generation speeded up evolution by increasing variety, but also because sex is a major component of organic happiness—he regards sexual pleasure as the greatest source of delight for lower creatures as well as human beings.

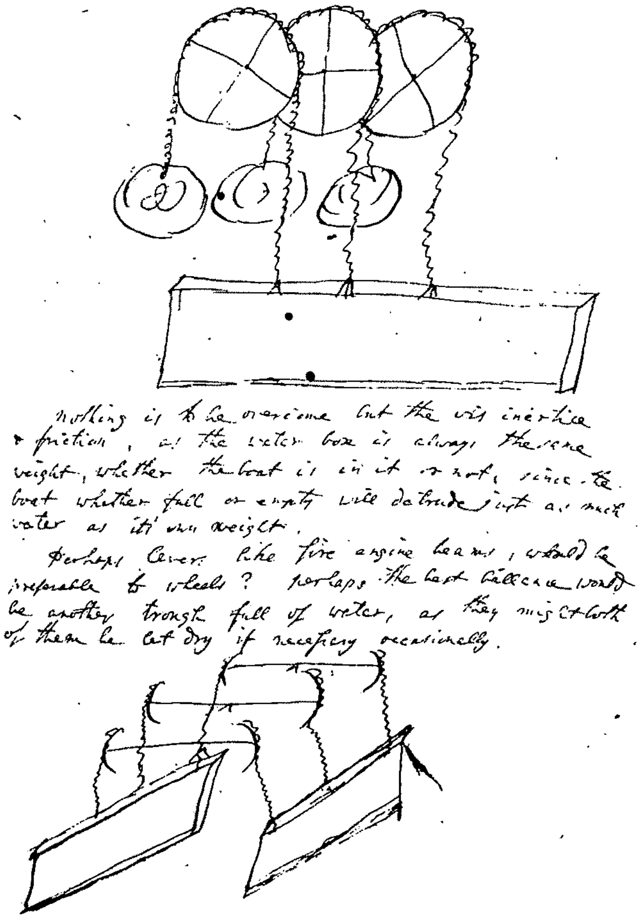
The third of Darwin's books is (for a change) a slim volume of 128 pages, entitled *A Plan for the Conduct of Female Education in Boarding Schools* (1797). Reprinted[46] in 1968, this is probably the most widely read of his books because of its significance in the history of education[47,48]. Darwin totally opposed the conventional idea of his time that girls should become feather-brained simpering misses: he wanted to see them "sound in body and mind". "The advantages of a good education consist in uniting health and agility of body with cheerfulness and activity of mind"[46]. His book, written for his daughters Susan and Mary Parker (who had set up a school), marks a quantum jump in the progress of girls' education, almost approaching modern ideas of sexual equality. Darwin deserves a small memorial in the pantheon of Women's Lib—though ironically the church where he was buried was burnt to the ground by suffragettes in 1914.

The fourth of Darwin's books, *Phytologia* (1800), is an impressive 600-page survey of vegetable life and all that sustains it, from carbon dioxide down to manures. *Phytologia* is a much better book than *Zoonomia* because it has so many ideas that are correct and new. One example is his discussion of plant nutrition, which is a great advance on any previous analysis. He specifies the process of photosynthesis, not of course in one neat equation (CO_2 + water + light energy = sugar + oxygen), but in separated sentences:

"This carbonic gas [CO_2] . . . is the principal food of plants. . . . Next to carbonic gas . . . water seems to afford the principal food of vegetables . . . because their solid fibres consist principally of carbon, and their fluids of water . . . When vegetable leaves are exposed to the sun's light they seem to give up oxygen gas. . . . Sugar is the principal nutriment of both animal and vegetable beings . . . the wonderful effect of vegetable digestion in producing sugar may be deduced from the great product of the sugar cane"[49].

Although Ingenhousz (1779) had shown that plants absorb carbon dioxide and give out oxygen in sunlight, Darwin goes much further towards the complete reaction, which was elucidated by Liebig and others some 40 years later.

Darwin also discusses other elements essential to plant nutrition, and was the first to recognise the importance of nitrogen and phosphorus[50]. He discusses nitrogen in detail, correctly specifying the role of ammonia and the formation of nitrates. He was well on the road towards defining the carbon and nitrogen cycles. Phosphorus he believed to be present in all plants because of their tendency to phosphoresce when decaying, and he recommends a search for phosphates as fertilisers—particularly calcium phosphate, since he also thought calcium was a vital element.



nothing is to be overcome but the vis inertiae & friction, as the water box is always the same weight, whether the boat is in it or not, since the boat whether full or empty will detrude just as much water as its own weight.

Perhaps levers like fire engine beams, would be preferable to wheels? perhaps the best ballance would be another trough full of water, as they might both of them be let dry if necessary occasionally.

Fig. 2 Some of Darwin's sketches for a canal lift, from his Commonplace Book (1777). Reproduced by courtesy of The Royal College of Surgeons of England.

Among the many other bright ideas in *Phytologia* are sewage farms, biological control of insects, engineering drawings for new water pumps and drill ploughs, a seminal discussion of the individuality of buds, and proposals for a system of artesian wells[51].

The pageant of life

The last of Darwin's five books is another long poem, *The Temple of Nature*, published posthumously in 1803. This is in my view his finest achievement, and its republication in facsimile by Scolar Press recently[52] should bring it back into circulation after 150 years of unjust neglect. In *The Temple of Nature* Darwin traces the evolution of life from microscopic specks in primaeval oceans through plant life, fishes, amphibia, land animals and birds:

> Organic Life beneath the shoreless waves
> Was born, and nurs'd in Ocean's pearly caves;
> First forms minute, unseen by spheric glass,
> Move on the mud, or pierce the watery mass;
> These, as successive generations bloom,
> New powers acquire, and larger limbs assume;
> Whence countless groups of vegetation spring,
> And breathing realms of fin, and feet, and wing[53].

The couplets are just as bright as in *The Botanic Garden* and Darwin manages to cram in even more information per line. But the really astonishing feature is the calm and correct description of the processes of evolution more than 50 years before the *Origin of Species* and 100 years before the details were generally agreed. For example, Darwin nonchalantly tells us about the transformation from fish through amphibia to reptiles. Some of the marine life, he says,

> Leaves the cold caverns of the deep, and creeps
> On shelving shores, or climbs on rocky steeps.
> As in dry air the sea-born stranger roves,
> Each muscle quickens, and each sense improves;
> Cold gills aquatic form respiring lungs,
> And sounds aerial flow from slimy tongues[53].

The pressures that shape evolution are expressed with equal verve as he describes the struggle for existence among animals, insects, fish and, here, plants:

> Yes! smiling Flora drives her armèd car
> Through the thick ranks of vegetable war;
> Herb, shrub, and tree, with strong emotions rise
> For light and air, and battle in the skies;
> Whose roots diverging with opposing toil
> Contend below for moisture and for soil[54].

"Where shall we find a benevolent idea to console us" amid so much slaughter, he asks. The answer is provided by his idea of organic happiness: he reminds us that

> when a Monarch or a mushroom dies,
> Awhile extinct the organic matter lies;
> but it soon teems with microscopic life again—
> Reproduction strives
> With vanquish'd Death—and Happiness survives.

Invention and research

Concentrating on Darwin's books, as I have done, brings out the variety of his accomplishments, but leaves unrecorded his contributions to technology and science. His Lunar Society friends looked on Darwin as primarily an inventor, and Boulton made a contract to pay him £1,000 for a developed version of his speaking-machine, which could pronounce many words "with so great nicety as to deceive all who heard it unseen". He constructed a mechanical "bigrapher", an early office copying machine, which worked well and inspired Watt to invent a chemical copying method "which beats your bigrapher hollow". He designed a number of water machines, including some elaborate pumps, an automated water closet, a wire-drawn ferry and a canal lift (Fig. 2), identical in design with those brought into operation 100 years later. Other paper designs include an artificial bird with flapping wings powered by a compressed-air bottle (Fig. 3), a sketch of a hydrogen-oxygen rocket motor, and telescopes made of numerous small lenses or mirrors: all three of these have proved prophetic[55].

Darwin did not devote much time, except in his medical work, to what we would call scientific research, but he still managed to achieve more than most scientists living today can hope for. His first two papers in the *Philosophical Transactions* are of little interest now, but they secured him election as a Fellow of the Royal Society in 1761, the first of five generations of Darwins to become Fellows. In one of his later papers, in 1785, he offers the first proper explanation of the principle of the artesian well[56]. But it is in his last paper in the *Philosophical Transactions*, in 1788, that he makes his most important contributions to physical science. In this paper[57] he gives the first clear statement of the principle of adiabatic expansion[58], fundamental to all heat engines: his discovery sprang from long familiarity with steam engines and Watt's problems in improving them. Darwin then applied the principle to explain the formation of clouds: "when large districts of air are raised . . . they become so much expanded by the great diminution of pressure over them . . . that . . . the air by its expansion produces cold and devaporates"[57]. Meteorology was a lifelong interest with him, and in addition to this discovery of the main mode of cloud formation he also recognised the existence of cold and warm fronts and of "rolling cylinders of air" in the lee of mountains[10].

Fig. 3 Darwin's artificial bird (1777). In this version the model is energised by a wound spring, but Darwin suggests a compressed-air bottle as an alternative source of power. Reproduced by courtesy of The Royal College of Surgeons of England.

In this article I have mentioned thirty-six subjects to which Darwin made pioneering contributions. I have left unmentioned thirty-nine others, including abolition of slavery, aesthetics, afforestation, animal camouflage, artificial insemination and aurorae—to quote only those beginning with 'a'. Of Darwin we can truly say, "We shall not look upon his like again". Yet schoolchildren and undergraduates in English-speaking countries complete their 'education' without hearing anything of Erasmus Darwin—a paradox for pedagogues and publishers to ponder. And, now that Darwin's poems are in print again, librarians have it in their power to popularise him.

Noradrenaline binding and the search for catecholamine receptors

Pedro Cuatrecasas, Guy P. E. Tell, Vincenzo Sica, Indu Parikh & Kwen-Jen Chang

Department of Pharmacology and Experimental Therapeutics, and Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205

The binding of ^{3}H-noradrenaline to intact cells and microsomes seems not to measure catecholamine receptor interactions, but rather a membrane catechol-binding protein which may be related to the enzyme, catechol-O-methyl transferase. True receptors are probably scarce and detection will require catecholamine derivatives of much higher specific activity than are at present available.

In the past few years considerable progress has been made in the identification of membrane-bound receptor structures for polypeptide hormones (insulin, glucagon, ACTH) in mammalian tissues and for cholinergic drugs in specialised tissues of certain fish. These studies have been based on the selective binding of highly radioactive (about 1 Ci μmol^{-1}) hormone derivatives to isolated cells or membrane preparations. These interactions demonstrate very strict specificity, saturability indicative of a finite and limited number of receptors, reversibility, and affinity and kinetic rate constants of binding which correlate with the biological properties of the hormone. Although radioactively labelled catecholamines have been used successfully for many years in the elucidation of important transport, storage and binding functions of adrenergic neurones[1–10], only recently have these labelled compounds been used to measure putative β-adrenergic receptors. Interactions between ^{3}H-labelled catecholamines and receptors have been described for isolated liver[11–13] and heart[14–17] microsomal preparations, spleen capsule[18], cultured myocardial cells[19], and turkey erythrocyte ghosts[20,21]. Here we describe our attempts to identify β-adrenergic receptors in intact cells and in microsomes from various tissues. Our data indicate that the binding of ^{3}H-noradrenaline does not measure catecholamine receptor interactions but rather a membrane catechol-binding protein which may be related to the enzyme, catechol-O-methyl transferase (COMT).

The binding of ^{3}H-(−)-noradrenaline to microsomal preparations (see legend to Table 1) from liver, heart and fat cells is a saturable process with respect to the hormone, although the binding is complicated by the existence of at least two separate binding processes and by an apparent cooperativity at low hormone concentrations. In microsomes stored at −20° C for 1 month the first plateau of binding indicates a capacity of about 1.4 nmol of hormone per mg of membrane protein in liver, 1.1 nmol in fat cell and 1.7 nmol in heart microsomes. These binding capacities are 10^3 to 10^4 times larger than for insulin[23,25] and glucagon[27,28] binding to fat and liver cell membranes. Using intact isolated fat cells, which are especially useful because of the homogenous nature of the cell type, absence of neural tissue and exquisite sensitivity to catecholamines, the data indicate a maximal ^{3}H-(−)-noradrenaline binding capacity of about 5×10^6 molecules per cell, which is at least 500 times greater than the binding capacity of these cells for insulin[22]. Myocardial cells in culture bind about 2.8×10^6 molecules per cell[19]. The concentration of unlabelled noradrenaline required to decrease the binding by 50% in fat, liver and heart cell microsomes and in intact fat cells is about 10^{-6} M.

These data must be interpreted very cautiously because the binding capacity of microsomes (in liver, heart and fat cells) increases strikingly during storage. Storage of fresh liver microsomes at −20° C in 50 mM sodium phosphate buffer resulted in a seven-fold increase in binding after 8 d and a fifteen-fold increase after 17 d; little further change occurs after 30 d. Storage of fresh liver microsomes at 4° C in 0.1 M Tris-HCl, *p*H 8.6, for 16 h results in a nine-fold increase in binding. Binding to stored fat cell microsomes, relative to insulin binding, is at least 200 times greater in the microsomes than in the intact cells.

Non-radioactive (+)- and (−)-noradrenaline compete in an identical way with ^{3}H-(−)-noradrenaline for binding to intact fat cells. The apparent affinity constants estimated from such inhibition studies are about 1 to 3×10^{-6} M. The apparent affinity constant calculated from dose-response studies of lipolysis (see legend to Table 1) is about 2×10^{-7} M. If sodium metabisulphite (20 μg ml^{-1}) is added to the medium to prevent oxidation of the catecholamine during the incubation (60 min, 37° C), the lipolytic dose response curves become hyperbolic and a half-maximal response was obtained at 6.5×10^{-8} M. Thus, there are substantial differences (about thirty-fold) between the apparent affinities for binding and for activation of a biological response in the identical, intact cell system.

The complete lack of stereospecificity for binding of ^{3}H-(−)-noradrenaline has been repeatedly confirmed in numerous systems including microsomal preparations from rat liver, heart, spleen and fat cells, sheep spleen capsule and pineal gland, and rabbit superior cervical ganglion. Even small degrees of stereospecificity are not detectable despite numerous variations in the concentration of ^{3}H-(−)-noradrenaline, temperature and time of incubation, rapidity of preparation of tissue, and composition of the buffer and cations. Others have also reported that the binding of catecholamines to liver[13] and heart[17] microsomes and turkey erythrocyte ghosts[21] is not stereospecific.

Specificity for catechols

Without exception, all compounds having a 3,4-dihydroxyphenolic moiety can effectively inhibit the binding of ^{3}H-(−)-

noradrenaline to microsomal preparations (Table 1). No reproducible differences were detectable in the relative ability of a widely divergent group of catechols to compete for binding. Pyrocatechol and dihydroxymandelic acid, which are not catecholamines, can displace binding effectively and completely. The presence of a third hydroxyl group at position 6 of the catechol ring (6-hydroxydopamine) resulted in an eight-fold lower apparent affinity. Compounds related to biogenic amines but lacking a catechol group are ineffective. Very similar results were obtained with microsomes from fat cells, liver and heart. The specificity of binding is thus restricted to catechol derivatives. This requirement for the catechol structure has also been reported for liver[12,13] and heart[17] microsomes and for turkey erythrocyte ghosts[21].

(+)-Noradrenaline, which can completely block the binding of ^{3}H-(−)-noradrenaline as effectively as (−)-noradrenaline, was ineffective in eliciting lipolytic responses in fat cells at concentrations (5 μg ml^{-1}) more than 1,000 times greater than those of (−)-noradrenaline which cause detectable lipolysis (Table 2). Furthermore, the (+)-isomer did not modify at all the lipolytic response to (−)-noradrenaline, even when its concentration was 1,000 times greater. Other catechols which effectively compete for binding, which possess virtually no intrinsic β-adrenergic activity in fat cells, and which do not modify the activity of (−)-noradrenaline or (−)-isoproterenol include dopamine, pyrocatechol (Table 2) and 3,4-dihydroxymandelic acid.

Table 1 Competition by Various Compounds with Binding of ^{3}H-(—)-Noradrenaline to Liver Cell Membranes

Addition	Concentration (μg ml^{-1})	Specific c.p.m. bound
None		17,700±500
(−)-Noradrenaline	0.5	9,200±200
	1.5	4,900±100
(+)-Noradrenaline	0.5	9,000±300
(−)-Isoproterenol	0.5	8,600±400
	1.5	4,800±300
Dopamine	0.5	6,900±500
	1.5	4,100±200
α-Methylnoradrenaline	0.5	8,800±300
3,4-Dihydroxymandelic acid	0.5	7,500±400
	1.5	4,600±300
Pyrocatechol	0.5	8,500±200
	1.5	4,900±300
6-Hydroxydopamine	1.5	14,100±200
	5.0	8,600±300
	10.0	5,100±100
(−)-Phenylephrine	50	16,800±400
Tyramine	50	17,500±500
Propranolol	500	14,200±500
Metanephrine	50	17,200±300
Phentolamine	50	16,900±500
Phenylethylamine	50	17,400±400

Triplicate samples (0.25 ml) containing 0.3 mg of protein per ml of Krebs-Ringer-bicarbonate (KRB) buffer (*p*H 7.4) were preincubated (24° C) for 3 min with the indicated compound, 0.2 μM ^{3}H-(−)-noradrenaline (2.6×10^5 c.p.m., 6.4 Ci mmol^{-1}) was added and incubations were continued for 30 min at 24° C. Binding was determined by Millipore membrane (cellulose acetate) filtration, which allows the samples to be cooled (4° C), filtered and washed (4° C) within 10 s, thus decreasing the probability of dissociation of the complex[22,23]. For all samples controls were performed in which unlabelled (−)-noradrenaline (50 μg ml^{-1}) was added before ^{3}H-(−)-noradrenaline; this binding was considered non-specific, and was subtracted to calculate specific binding[22,23]. Non-specific binding is generally less than 0.5% of the radioactivity in the medium and less than 10% of the total bound except in fat cells and turkey erythrocytes and ghosts where at high (10^{-6} M) hormone concentrations a larger part may be non-specific. Liver membranes (Sprague-Dawley rats) are the microsomal pellet of homogenates prepared in 0.25 M sucrose[24,25]. Fat cell membranes represent the total particulate fraction of intact fat cells homogenised in Krebs-Ringer-bicarbonate buffer[26]. Rat heart microsomes were prepared from homogenates (Polytron, 3 min, 0.25 M sucrose) by the centrifugation procedures described[14,17], which result in very low yields of material, as well as by collecting the 2,500*g* (15 min) pellet after discarding the material, sedimenting at 300*g* (15 min); the results were similar with both preparations. Intact turkey erythrocytes were used after washing thoroughly with ice-cold 50 mM sodium phosphate, *p*H 7.4, and suspending in KRB buffer, *p*H 7.0. Ghosts were prepared each day by freezing and thawing followed by washing as described above; the ghosts are devoid of haemoglobin and most are nucleated. Glass fibre paper filters (Whatman, GF/C 2.4 cm) were used in the filtration assay of erythrocytes and ghosts since the high concentrations (1 to 8×10^8 cells ml^{-1}) required to detect binding caused plugging of Millipore filters. All binding studies were performed in KRB buffer (*p*H 7.4), although generally similar findings were obtained with phosphate buffers.

Table 2 Lipolytic Activity of Catechol Substances, and their Effect on the Lipolytic Activity of (—)-Noradrenaline in Isolated Fat Cells

Addition	Concentration (ng ml^{-1})	Glycerol released
None		13.6
(−)-Noradrenaline	10	48.7
	50	71.0
(−)-Isoproterenol	0.5	27.4
(+)-Noradrenaline	500	14.4
	5,000	14.6
Pyrocatechol	2,000	14.5
Dopamine	500	16.2
3,4-Dihydroxymandelic acid	500	15.1
(+)-Noradrenaline+	500	
(−)-Noradrenaline	10	51.4
(−)-Isoproterenol	0.5	28.2
Pyrocatechol+	2,000	
(−)-Noradrenaline	10	49.8
Dopamine+	500	
(−)-Noradrenaline	10	52.9
3,4-Dihydroxymandelic acid+	500	
(−)-Noradrenaline	10	50.1

Fat cells were incubated for 80 min in KRB buffer–3% albumin, 7 μg per ml of sodium metabisulphite, and the indicated compound. Lipolysis was determined by measuring the release of glycerol in the medium[30,31]. Results are expressed as μmol of glycerol per mmol of cell triglyceride. The lipolytic potency of (−)-phenylephrine, pronethalol, phentolamine, and 6-hydroxydopamine was at least 100 times lower than that of (−)-noradrenaline while the potency of (−)-isoproterenol was five to ten times greater.

(+)-Noradrenaline did not stimulate the activity of adenylate cyclase in microsomes of isolated fat cells except at concentrations 200 to 1,000 times (depending on the batch) greater than those of (−)-noradrenaline (Fig. 1). This probably resulted from trace contamination with the (−)-isomer. The (+)-isomer in ten- to fifty-fold molar excess did not inhibit the activity stimulated by (−)-noradrenaline (Fig. 1). The catechol compounds, dihydroxymandelic acid, α-methyl dopa and pyrocatechol did not stimulate adenylate cyclase activity at concentrations as high as 10^{-4} M, and they did not inhibit (at 10^{-4} M) the stimulation (5.5-fold) caused by 5×10^{-6} M (−)-noradrenaline.

In liver microsomes maximal stimulation of adenylate cyclase (conditions as in Fig. 1) occurred with 10^{-5} M (−)-noradrenaline. Concentrations higher than 0.1 mM reversed the stimulation, presumably non-specifically. (+)-Noradrenaline did not inhibit the (−)-isomer in liver, even at 100-fold higher concentrations, provided its concentration did not exceed 1 mM. Such high (+)-noradrenaline concentrations were non-specifically toxic since they also inhibited activities stimulated by glucagon and fluoride. Fluoride (10 mM) stimulation was inhibited about 18% and 60%, and glucagon (10^{-6} M) was inhibited 20% and 100%, by 1 mM and 10 mM, respectively, of (+)-noradrenaline.

The non-catechol, *m*-methanesulphonamide derivative of isoproterenol, Soterenol (compound number 49)[32,33], stimulated lipolysis in fat cells and adenylate cyclase activity in fat cell membranes, and its activity was blocked by propranolol. Its apparent affinity was similar to that of (−)-noradrenaline. Despite this, very high concentrations (0.5 mM) of Soterenol (gift from Dr W. T. Comer, Mead Johnson) only decreased

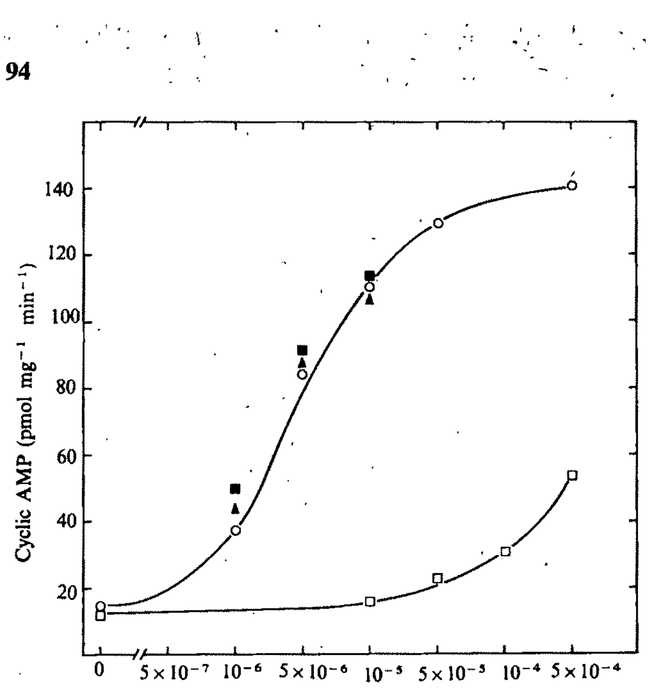

Fig. 1 Effect of (+)-noradrenaline on (−)-noradrenaline stimulation of adenylate cyclase activity in isolated fat cell microsomes. The incubation mixture (0.1 ml) contained 25 mM Tris-HCl (pH 7.6), 5 mM $MgCl_2$, 0.1 mM $MnCl_2$, 0.1 mM GTP, 2.5 mM aminophylline, 0.1% (w/v) albumin, 0.1 mM α-^{32}P-ATP (6×10^6 c.p.m.) and 100–200 μg of membrane protein; 5 mM phosphoenolpyruvate and 60 μg ml^{-1} of pyruvate kinase were used to regenerate ATP. After 5 min at 37° C, the tubes were placed in boiling water for 2 min. A recovery mixture (1.0 ml) containing ^{3}H-cyclic AMP was added to each sample. Cyclic AMP was isolated on a column containing 1 g of alumina that was eluted with 2.0 ml of 25 mM Tris-HCl (pH 7.6). Values are averages of triplicate replications. □, (+)-Noradrenaline; ○, (−)-noradrenaline; ▲, (−)-noradrenaline with 10^{-5} M (+)-noradrenaline; ■, (−)-noradrenaline with 5×10^{-5} M (+)-noradrenaline.

the binding of ^{3}H-(−)-noradrenaline (0.2 μM) by only 13% in fat cells, 14% in liver, and 22% in heart microsomes.

By two different methods the ^{3}H-(−)-noradrenaline which binds to liver, heart and fat cell membranes could not dissociate over a 40- to 80-min period at 4° C, 24° C, or 37° C (Fig. 2). The results were similar if the hormone-membrane complex was incubated for only 10 min at 24° C or 4° C before dissociation was studied, and this lack of dissociation was observed with fresh or stored microsomes. These results contrast with the immediacy of reversal of the catecholamine effect observed upon removal of the hormone from the medium in a variety of biological systems, including fat cells. HCl (0.4 N) did not reverse but instead slightly enhanced the complex between noradrenaline and liver or heart microsomes (Fig. 2, insert). Guanidine-HCl (5 M) increased, and 0.4 N NaOH depressed, the binding. The essentially irreversible nature of the binding and the facile oxidation of catechols have hindered chemical identification of the membrane-bound ^{3}H.

Relation with enzyme COMT

In agreement with others[13,17], proteolytic (Pronase) digestion of membranes destroyed subsequent binding activity, indicating that protein components are involved. The specificity of binding described above is very different from that observed for the transport, storage and binding functions of adrenergic neurones or storage vesicles[1–10]; furthermore, isolated fat cells and erythrocytes are devoid of such structures.

The strict requirement of the binding process on the presence of a catechol function suggests a possible relationship with the enzyme, catechol-O-methyl transferase (COMT). This enzyme has similar affinities for a wide variety of catechols, even for those lacking a ring side chain, and it does not distinguish between (+)- and (−)-forms of noradrenaline[34–37]. Although COMT is present in the soluble fraction of most tissues, its presence in microsomes is well established[38–40]. In isolated fat cells the enzyme is found predominantly in a membrane-bound form[40]. Although the particulate and soluble enzymes differ in certain respects[38], both demonstrate broad substrate specificity[38,39].

The presence of COMT activity[34,35] in the liver, fat and heart microsomal preparations used in these studies was confirmed using ^{3}H-(−)-noradrenaline or ^{14}C-S-adenosylmethionine[41] as substrates. As observed for COMT[13,17], reagents that blocked sulphydryl groups (such as p-chloromercuribenzoate) also blocked ^{3}H-(−)-noradrenaline binding. Also like COMT, (−)-noradrenaline binding required divalent cations; binding decreased 50% with 2 mM EDTA in liver membranes. Some well known[37,42,43] inhibitors (tropolone, pyrogallol, quercetin and U-0521) of COMT which do not have β-adrenergic activity could also inhibit the binding to liver and heart microsomes (Table 3).

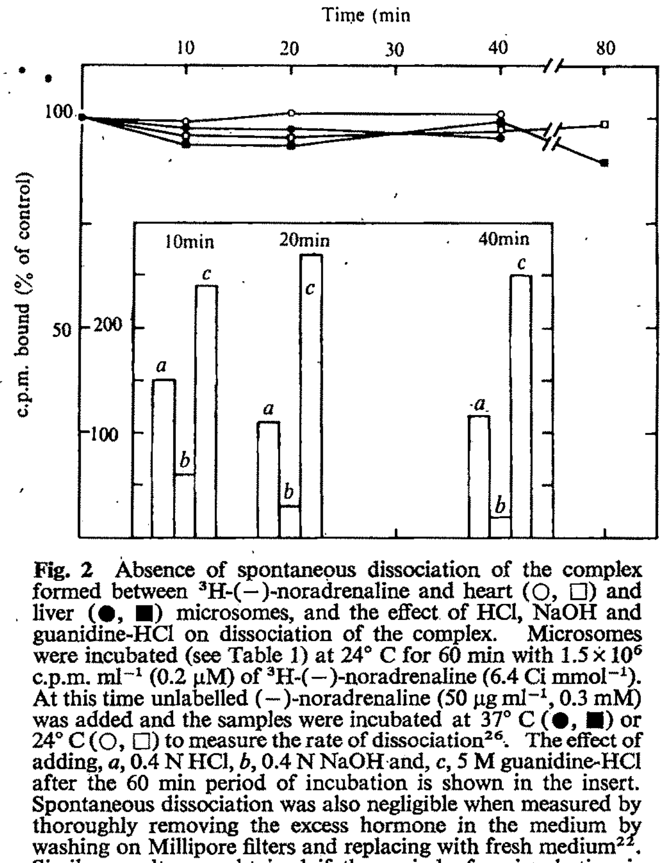

Fig. 2 Absence of spontaneous dissociation of the complex formed between ^{3}H-(−)-noradrenaline and heart (○, □) and liver (●, ■) microsomes, and the effect of HCl, NaOH and guanidine-HCl on dissociation of the complex. Microsomes were incubated (see Table 1) at 24° C for 60 min with 1.5×10^6 c.p.m. ml^{-1} (0.2 μM) of ^{3}H-(−)-noradrenaline (6.4 Ci $mmol^{-1}$). At this time unlabelled (−)-noradrenaline (50 μg ml^{-1}, 0.3 mM) was added and the samples were incubated at 37° C (●, ■) or 24° C (○, □) to measure the rate of dissociation[26]. The effect of adding, *a*, 0.4 N HCl, *b*, 0.4 N NaOH and, *c*, 5 M guanidine-HCl after the 60 min period of incubation is shown in the insert. Spontaneous dissociation was also negligible when measured by thoroughly removing the excess hormone in the medium by washing on Millipore filters and replacing with fresh medium[22]. Similar results are obtained if the period of preincubation is short (10 min), or if the temperature of preincubation is 4° C.

S-Adenosyl-L-methionine (SAM), a compulsory substrate for COMT activity[34,35,43], markedly increased (two- to four-fold at 1 mM) the rate of binding of ^{3}H-(−)-noradrenaline to liver and heart microsomes (Fig. 3); effects were detectable at concentrations below 0.1 mM. The effect of SAM was most pronounced on freshly prepared microsomes, and little effect could be observed in preparations stored frozen for more than 3 weeks. SAM did not dissociate bound radioactivity even if added after removal of the free ^{3}H-(−)-noradrenaline in the medium. Thus, SAM did not simply increase the rate of turnover of the catecholamine-membrane complex. The normal product of SAM hydrolysis by COMT, S-adenosylhomocysteine (SAH), inhibited weakly the binding to heart and liver microsomes; 10% to 20% inhibition (measured at 10 min, 24° C) occurred in the presence or absence of SAM (1 mM) with 5 mM SAH. The normal (−)-noradrenaline

Table 3 Effect of Inhibitors of Catechol-O-Methyl Transferase on Binding of ^{3}H-(—)-Noradrenaline to Liver Membranes

Addition	Concentration (μg ml^{-1})	Specific ^{3}H-noradrenaline bound (c.p.m.)
None		8,200 ± 300
(−)-Noradrenaline	2.5	3,300 ± 100
	0.5	5,400 ± 300
	0.1	7,600 ± 200
Tropolone	0.5	5,900 ± 100
	0.1	6,800 ± 200
U-0521	10	6,300 ± 100
	0.5	7,300 ± 300
Pyrogallol	10	3,600 ± 100
	0.5	6,100 ± 200
Quercetin	10	3,100 ± 200
	0.5	6,100 ± 300

Membranes (0.2 ml containing 1.1 mg of protein per ml) were incubated (24° C) for 3 min with the indicated compound followed by 60 min at 4° C with 0.9 μM ^{3}H-(−)-noradrenaline (4.8×10^5 c.p.m., 6.4 Ci mmol^{-1}) as described in Table 1. Similar results were obtained by incubating for 30 min at 24° C, and with heart microsomes. U-0521 is 3,4-dimethoxy-5-hydroxybenzoic acid[37].

product of transferase activity, (−)-normetanephrine, did not alter the binding (including rates) of ^{3}H-(−)-noradrenaline (0.1 μM) in the absence or presence of SAM even when tested at concentrations as high as 0.3 mM. The material bound to membranes was probably not a simple product of COMT catalysis.

The close analogue of SAM, S-adenosylethionine (SAE), profoundly decreased the binding of ^{3}H-(−)-noradrenaline to heart and liver microsomes (Table 4). Significant effects occurred with 5 μM SAE. SAE could decrease the binding even more effectively than nearly saturating concentrations (5 μg ml^{-1}) of unlabelled (−)-noradrenaline. Inhibition was observed only if SAE is added before ^{3}H-(−)-noradrenaline, and no dissociation was seen if it was added after the complex has incubated for 10 to 30 min at 24° C or 10 to 60 min at 4° C, even if the microsomes were washed before testing. SAE abolished the effects of SAM described above, and Dixon plots suggested competitive kinetics of inhibition with an apparent dissociation constant of about 80 μM (heart microsomes). SAE is a potent inhibitor of liver and heart microsomal COMT activity. When assayed with 30 μM ^{14}C SAM and 1 mM 3,4-dihydroxybenzoic acid (under conditions giving zero order kinetics), concentrations of SAE of 0.3 mM, 30 μM, and 3 μM inhibited COMT activity of liver microsomes by 85%, 56% and 15%, respectively.

Table 4 Inhibition of Binding of ^{3}H-(—)-Noradrenaline to Heart and Liver Membranes by S-Adenosylethionine

Addition	Total ^{3}H-noradrenaline bound (c.p.m.) Liver microsomes	Heart microsomes
None	13,500	7,200
(—)-Noradrenaline, 5 μg/ml	800	600
S-Adenosylethionine, 5 mM	500	400
1 mM	850	1,000
0.2 mM	1,250	3,800
40 μM	5,900	4,900
5 μM	9,300	6,700

The experiments were performed as described in Fig. 3. Incubations (24° C, 40 min) (0.2 ml) contained 0.24 mg (liver) or 0.30 mg (heart) microsomal protein and 1.2×10^5 c.p.m. (liver) or 2.0×10^5 c.p.m. (heart) of ^{3}H-(−)-noradrenaline (6.4 Ci/mmol).

3-Mercaptotyramine, which selectively and irreversibly inactivates soluble COMT presumably by forming disulphide complexes at the active site of the enzyme[45], is a very potent inhibitor of noradrenaline binding to liver and heart microsomes. Incubation of heart microsomes for 15 min (37° C) with 0.3 mM, 30 μM, 6 μM, 1 μM and 0.3 μM 3-mercaptotyramine (a gift from Dr C. R. Creveling) decreased the subsequent binding (30 min, 24° C) of ^{3}H-noradrenaline (0.8 μM) by 100%, 91%, 73%, 28%, and 15%, respectively.

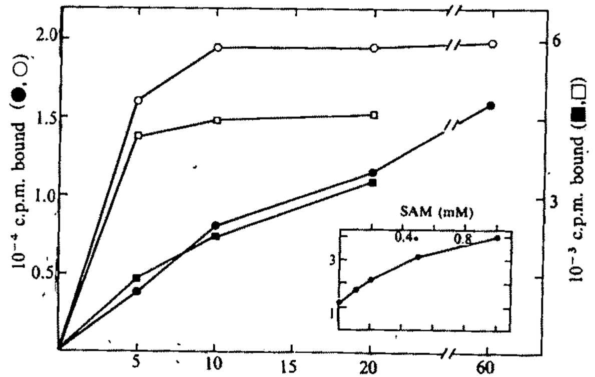

Fig. 3 Effect of S-adenosylmethionine (SAM) (○, □) on the binding of ^{3}H-(−)-noradrenaline (4.5×10^5 c.p.m. for heart, 1.9×10^5 c.p.m. for liver; 6.4 Ci mmol^{-1}) to liver (●, ○) and heart (■, □) microsomes. SAM was added immediately before the radioactivity. The protein content was 0.24 (heart) or 0.21 (liver) mg per 0.2 ml, and incubations were at 24° C. Insert shows the effect of SAM concentration on heart microsomes measured at 5 min.

Since noradrenaline binding is essentially irreversible, and since SAM does not release the bound material, the binding may represent an aberrant, covalent enzyme-substrate intermediate which is not susceptible to completion by the normal catalytic process. The very large increase in binding capacity during storage of microsomes or by treatment with Tris-HCl may reflect such an alteration of the enzyme. It may be relevant that dithiothreitol (DTT) potently inhibits the binding to liver and heart microsomes. Binding (30 min, 24° C) of 0.4 μM ^{3}H-(−)-noradrenaline to heart microsomes is decreased by 82%, 73%, 48% and 15% by 1 mM, 0.25 mM, 60 μM and 15 μM, respectively, of DTT. Although the activity of soluble COMT (heart or liver) is not inhibited by 3 mM DTT, the activity of microsomal, particulate preparations is enhanced four- to six-fold by concentrations of DTT as low as 0.6 mM. DTT thus may revert an altered particulate enzyme into a form that no longer binds catechol substrates irreversibly.

Solubilisation of catechol binding protein

As described by others[13,15,16], the binding protein can be solubilised from microsomes with non-ionic detergents. We studied extensively the material solubilised from fat and liver microsomes with Triton X-100. The soluble protein-^{3}H-noradrenaline complex would be assayed by precipitation with 65% $(NH_4)_2SO_4$, followed by Millipore filtration as described for microsomes, or by gel filtration on Sephadex G-25. As in microsomes, binding was destroyed by Pronase, was saturable with two distinct plateaus (in liver, K_d values were about 3×10^{-7} M and 2×10^{-5} M), was suppressed by unlabelled hormone, was lacking in stereospecificity, demonstrated specificity only for catechols, and could not be dissociated even during 2 h at 37° C. Binding was inhibited by SAE (50 μM inhibited the binding of 0.3 μM ^{3}H-noradrenaline to liver extracts by 75%), and the rate of binding was increased by SAM. 3-Mercaptotyramine[45] inhibited binding profoundly; 6 and 1 μM (15 min, 37° C) inhibited subsequent binding (liver) by 97% and 84%, respectively. Binding was also very sensitive to DTT. A most unusual property was the ability of 5 M guanidine-HCl and 2% sodium dodecyl sulphate to increase binding by 50% and by two- to five-fold, respectively; unlabelled hormone (10 µg per ml) prevented this increased binding, which required tissue extract, and ^{3}H-noradrenaline did not bind to the detergent or to guanidine. Binding was suppressed in 2 M NaCl and in 8.3 M guanidine-HCl, *p*H 1. The complex, once formed, did not dissociate with 2% sodium dodecyl sulphate, 0.5 N HCl, or by boiling for 4 min.

Binding to turkey erythrocytes

In accordance with the report of Bilezikian *et al.*[21], binding of ^{3}H-(−)-noradrenaline to turkey erythrocyte ghosts (see legend, Table 1) was not stereospecific and only required the catechol moiety. As in microsomes, binding was only very weakly inhibited by Soterenol, and it was inhibited by SAE and by 3-mercaptotyramine (although higher concentrations were required). Low concentrations (0.2 mM) of DTT inhibited binding, but not as profoundly as in microsomes. Unlike liver and heart microsomes, the bound ^{3}H-noradrenaline could dissociate spontaneously.

There were striking differences between the binding to intact erythrocytes and to ghosts. Freshly prepared ghosts bound thirty to seventy times more noradrenaline (per cell) than intact cells. Storage of the ghosts (−20° C, 3 d) further increased binding by a factor of two to three; binding did not change upon storing intact cells at 4° C for 3 d. An intact cell could bind a maximum of about 14,000 noradrenaline molecules, while a ghost could bind about 650,000. Intact human erythrocytes, which are unresponsive to catecholamines[46], bound about 5,000 molecules per cell.

Maximal stimulation (seven-fold) of adenylate cyclase activity (methods as in Fig. 1) in ghosts occurred with 5×10^{-5} M (−)-noradrenaline; concentrations higher than 0.5 mM reversed the stimulation, as described for microsomes. The activity of the (−)-isomer was not reversed by 100- to 500-fold higher concentrations of (+)-noradrenaline provided these did not exceed 10^{-3} M, which, as described earlier, non-specifically suppress activity. Pyrocatechol, dihydroxymandelic acid and α-methyl dopa did not stimulate the enzyme, and these compounds at 10^{-4} M and 5×10^{-4} M did not inhibit the stimulation (5-fold) of 5×10^{-6} M (−)-noradrenaline. The isoproterenol (10^{-8} M) enhanced rate of sodium outflux (15 min) in turkey erythrocytes was not modified by a 1,000-fold molar excess of DL-dopa, dopamine, vanilmandelic acid, or 3,4-dihydroxyphenylacetic acid, compounds that completely block the binding of ^{3}H-isoproterenol[46]. Although these compounds (1,000-fold excess, 0.2 mM) decreased the levels of cyclic AMP stimulated (90 min) by isoproterenol, the inhibition was only about 15%, and possible non-specific toxicity was not examined[46].

Stereospecific binding was not demonstrable in intact erythrocytes, despite the low number of binding sites compared to ghosts. The residual binding observed in the presence of pyrocatechol, 3-mercaptotyramine, SAE or DTT did not reveal stereospecificity. Despite differences in the binding between turkey erythrocytes (and ghosts) and mammalian cells or microsomes, the essential features indicate that the binding did not reflect a true β-adrenergic receptor interaction. The possible relation of binding to catechol transport has not been examined.

The binding of ^{3}H-(−)-noradrenaline to subcellular particles or cells cannot be reconciled with the view that such binding reflects β-adrenergic receptor interactions. The single most compelling argument is that certain compounds which completely prevent this binding have no intrinsic biological activity and do not measurably alter the biological activity of (−)-noradrenaline. Binding is probably related to a totally separate process which shares with catecholamine receptors only the property of recognising catechol moieties. It must be concluded that if such putative receptors exist in the materials examined, they must represent a negligible fraction of the actual binding of ^{3}H-noradrenaline observed. Estimates of the possible number of receptors in fat cells from lipolytic studies using a catecholamine, N-[2-(*p*-hydroxyphenylpropyl)]-(−)-noradrenaline (gift from Dr J. van Dijk, Philips-Duphar, The Netherlands), of very high apparent affinity (about 3×10^{-10} M), with the assumption that 10% of the molecules in the medium are bound, give a maximum figure of 10^5 sites per cell. This is five to ten times greater than the maximum number of insulin or glucagon molecules that are bound per fat cell[22]. The numbers of noradrenaline binding sites in microsomes or cells are orders of magnitude greater than the corresponding figures for peptide hormones. It may therefore not be surprising that specific receptors cannot be detected in the presence of other binding processes which exist in great excess. In turkey erythrocytes, however, the number of binding sites is very low. Assuming a cell radius of 4 µm, intact turkey cells have a binding density of about seven sites per µm^2, and ghosts about 300 sites per µm^2. (The density of insulin receptors in fat cells is 1 to 5 per µm^2, depending on cell size[22].) But despite the scarcity of interfering catechol-binding sites in erythrocytes, stereospecific binding cannot be detected.

Many attempts to detect stereospecific binding in cells and membranes after experimentally suppressing (with pyrocatechol, specific inhibitors of COMT, SAE, 3-mercaptotyramine, DTT, EDTA and treatment with *p*-chloromercuribenzoate or iodoacetamine) the catechol-binding structures have failed. In these cases the residual binding is very low. This is consistent with the probable scarcity of true receptors. Detection will probably require catecholamine derivatives of much higher specific activity than are at present available. The ^{125}I-labelled peptide hormones used to study receptors are 100 to 300 times more radioactive than ^{3}H-(−)-noradrenaline.

For technical reasons the ligand used to detect receptors should have the highest possible affinity. It can be calculated from $K_d = k_1/k_{-1}$ (K_d, dissociation constant; k_1 and k_{-1}, rates of association and dissociation, respectively) that a complex having a k_1 of 5×10^5 mol^{-1} s^{-1}, which is a very low estimate (ten times less than that of insulin receptors, 10^4- to 10^5-fold less than diffusion encounters), and a K_d of 5×10^{-8} M would exhibit a half-life of about 30 s. Since the true figure may well be ten times lower, it is possible that extensive dissociation of the complex can occur during washing of the particles or cells in the binding assay, especially if it is not performed at low temperatures.

This work was supported by grants from the US National Institutes of Health, US National Science Foundation, and the Kroc Foundation, Santa Ynez, California. P. C. is a recipient of a USPHS Research Career Development award. K.-J. C. is a recipient of a USPHS Research Postdoctoral Fellowship award. We thank Dr Solomon Snyder for helpful discussions, and Dr Cyrus Creveling for suggesting that catechol-binding may be related to particulate COMT, and L. Wu for technical assistance.

Typographical errors and technological solutions

Donella H. Meadows & Dennis L. Meadows

Dartmouth College, Hanover, New Hampshire 03755

A recently reported typographical error in our global computer simulation model did exist, but had only a small quantitative effect on the published results. The error was not responsible for the pollution crisis mode; its removal does not stabilise the model system and the conclusions are unaffected by the numerical change.

In a recent issue of *Nature*[1], Boyle reports finding a typographical error in the computer simulation model used as a background for our book, *The Limits to Growth*[2]. Boyle states that the error is responsible for the pollution crisis mode of the model and concludes that "affluence without restrictive social policies is apparently attainable". For the benefit of the many research groups currently working with our technical report on the model[3], as well as the general public interested in the policy questions raised by *The Limits to Growth*, we would like to clarify the nature of this error and its effect on our conclusions.

Error

Tabular functions are often used in system dynamics models to express the nonlinear relationship of one variable to another. In early versions of the world model we employed such a table function to represent the relative amount of pollution released as a function of the industrial output per capita. The table, called Pollution Generation Multiplier from Output Table (PGMOT), contained one mistyped value as indicated below (the values in the table express pollution relative to total global emissions in 1970, and they correspond to values of industrial output per capita over the range from $0 to $1,600 in steps of $200).

```
T PGMOT=0/0.87/1.64/2.5/3.5/4.5/5.5/6.5/7.5
```

The mistyped number corresponds to a value of industrial output per capita of $1,000 (equivalent to a GNP per capita of about $4,000) and will cause an error in the model output whenever the value of industrial output per capita lies between $800 and $1,200. That situation occurs in three of the twelve model runs shown in *The Limits to Growth*, Figs 40, 41 and 42. In the other nine runs, industrial output per capita remains below the region where the PGMOT function is in error, and the error has no effect.

The typing error in PGMOT was corrected in our laboratory before the first draft of the technical report was completed in April 1972. To our knowledge, no research group working with any draft of the technical report has been given a program containing the error. We were under the impression that the figures in *The Limits to Growth* were drawn from the corrected version of the program, and we are indebted to Boyle for pointing out our mistake. The error, however, has no effect on the general message of the book and it does not alter our conclusions in any way.

That statement may be better understood if we examine the error in the full context of the model assumptions.

Implications

The basic assumptions of the world model are:

(1) Population and capital by their very nature tend to grow exponentially; the amount added to either population or capital each year is partially determined by the amount of population or capital already present. This exponential tendency is enhanced by current short-term, pro-growth value systems.

(2) There are limits to the growth of any physical quantity on a finite Earth. The carrying capacity for human population and industry is variable; it can be expanded by technology, and it can be diminished by misuse, erosion or depletion of resources.

(3) There are significant delays in the feedback processes that act to contain population and capital within the global carrying capacity. Some of these feedback delays arise from biological or physical processes (such as population ageing and the passage of a pollutant up a food chain) and others from social processes (such as perception and communication delays and resistance to change).

These three assumptions, considerably elaborated, constitute the world model. The conclusion that follows from them is that the present global population-capital system is dynamically unstable. The combination of rapid physical growth and long feedback delays can lead to a temporary overshoot of the sustainable physical limits to population and capital. During the overshoot period the carrying capacity can be eroded by overuse, leading to an eventual decline of population and industry. The overshoot can be entirely avoided by a change of values to favour a deliberate stabilisation of population and capital. The quality of life in the stabilised state can be greatly enhanced by technologies that preserve resources and abate pollution. Technological changes alone, however, unaccompanied by value changes that lead to deliberate slowing of growth, can lead to greater overshoot by temporarily enhancing exponential growth and by masking and further delaying the feedback pressures from physical limits.

This general conclusion is the most significant one to be drawn from the model or from *The Limits to Growth*. The model provides no information about whether the value changes that lead to stabilisation will actually occur. No single computer run of the twelve presented in *The Limits to Growth* can be interpreted as an exact prediction of the future state of the world—in fact the precise quantitative features of the model runs were deliberately removed to discourage such interpretation. The output of such a general, aggregate model can never be, and was never claimed to be, numerically accurate. Three different models, all built around the same assumptions but incorporating different degrees of detail and different numerical parameters, have produced quantitatively different but qualitatively identical conclusions[2-4]. These qualitative conclusions about system instability and the conditions that lead to stability are the only ones upon which any policy recommendations have been based.

Although the numerical error reported by Boyle does influence the quantitative output of three computer runs, it does not influence the system instability reflected in those runs, nor does it invalidate or even address any of the basic assumptions in the model. The version of Fig. 42, illustrated in Boyle's paper, still shows a severe overshoot of industrial capital, followed by an uncontrolled collapse. Boyle states, "The pollution crisis forecast . . . has been traced to a typographical error in the program" but pollution crises occur in Figs 36 and 37 of *The Limits to Growth*, where the error is not operative, and in several figures in both *World Dynamics* (pages 10, 75, 96, 100, 105, 108–111) and the technical report[3] (chapter VII, runs 7, 8, 13, 14) where the error is not even present.

Stabilisation policies

Boyle goes beyond the question of the typographical error to suggest an alternative set of policy changes that will stabilise the model system. Many such stabilising policy sets exist, each of which leads to a quantitatively different equilibrium state. The one common characteristic of these stabilising policies is that they supply some forward-looking social pressure against growth in place of the delayed-feedback physical pressures of the natural system.

The pressures that Boyle has selected—on agricultural development, capital investment, advertising and consumer demand for food and industrial output—are not different in kind from those we used to stabilise the model. (We called our stabilising measures "deliberate constraints on growth"; Boyle prefers to call his "rational economic policies".) The major difference is that he excludes any deliberate pressure on population growth. *The Limits to Growth* model considerably underestimates the growth potential of the human population, as discussed in detail in the technical report[3] (chapter II) and so the question of whether policies that stabilise population in that model will stabilise a real population must be considered. In any event, *The Limits to Growth* was intended to raise the question of which pressures against growth will be effective and which we would prefer to live under, not to settle the question. Dr Boyle's alternative suggestion is a positive contribution to a debate that is just beginning.

We must take some issue, however, with Boyle's "real conclusion" that there is "hope for the technological solution". Even the crude representations of technology in *The Limits to Growth* model and in Boyle's paper do not lead to that conclusion. Furthermore, technology in this model is assumed to be immediate, perfectly effective, free of cost, and free of any unforeseen side effects. This lack of realism was utilised in *The Limits to Growth* only to illustrate the extreme case. In the technical report[3] (chapter VII, runs 21, 22, 23) and in detailed working papers[5] (chapters 3, 6 and 8), capital costs of technology and implementation delays are included. In these more realistic representations, reliance upon technology to bring an orderly transition to system equilibrium looks even less feasible.

Technological advance can, and we hope will, do much to make life more livable during the transition and in the stable state. We do not believe, however, that technology alone can produce a solution to problems arising from an inconsistent, short-term, anthropocentric set of values based primarily on the concept of an infinite Earth. Social problems ultimately require social solutions, not technological ones. It seems unpleasant for us to recognise the fact, but the sooner we do so, the sooner the necessary solutions are likely to be found.

Lepton Creation and the Dirac Relationship between Fundamental Constants

CAVALLO[1] has proposed an interpretation of the large number ratios between some of the fundamental constants occurring in physics and cosmology, in terms of rotating cosmological models. The purpose of this communication is to suggest another interpretation of these large dimensionless numbers in terms of lepton creation.

The starting point of this theory is the usual action principle for gravitation and electromagnetism but with the difference that charged leptons can be created or annihilated in the cosmological space-time. That is, the worldlines of these particles can have a beginning or an end, or both. The action can be written either in the field form or in the form of action at a distance[2]. The variation of the worldline of a lepton of mass m and charge e gives the following condition at the beginning or end of a worldline:

$$m\mathbf{u}_i = -eA_i \tag{1}$$

where A_i is the four-potential from the rest of the particles in the Universe and $\mathbf{u}_i$ is the four-velocity of the lepton.

I now apply this to a Robertson–Walker space-time used by most cosmologists, and used by Dirac in his discussion[3]. This represents an expanding homogeneous and isotropic Universe. In any given cosmological model of this type, it is possible in principle to calculate the A_i from charges of one species, although in practice the relevant integral may not be expressible in terms of elementary functions[4]. But if the Universe as a whole is electrically neutral the total A_i appearing on the right hand side of equation (1) will be zero.

I now propose a departure from strict neutrality in the following way. Suppose we consider particles of electric charge e. Although cosmological models differ in detail (such as deceleration parameter, the value of the λ constant, big bang or steady state, and so on), only the time-like component of A_i from all these particles is non-zero and it has the magnitude of the order of

$$Ne/R \ (R = c/H) \tag{2}$$

where N is the number of such charges in a spherical region of radius R. The parameters c and H in equation (2) are the velocity of light and the present value of the Hubble constant respectively. In the case of strict charge neutrality particles of opposite charge $-e$ will make an equal contribution $-Ne/R$ and thus cancel equation (2) exactly. But if the charge balance is a statistical effect, small fluctuations from it are likely to be present. This would mean that there is an overall electrostatic potential of the order

$$A_4 \sim \pm N^{1/2}e/R \tag{3}$$

The fluctuation effect assumed in equation (3) is of the order $N^{-1/2}(\sim 10^{-40})$.

Using equation (3) in equation (1), for a lepton created at rest in the cosmological substratum,

$$mc^2 = \mp N^{1/2}e^2/R \tag{4}$$

Since the left hand side is positive, the creation condition specifies that only the + sign on the right hand side is applicable. That is, only charge of one species can be created in a given region. We will return to this point again at a later stage, accepting for the time being the + sign in equation (4).

The relation (4) can be rewritten in a more familiar form:

$$R/(e^2/mc^2) \simeq N^{1/2} \tag{5}$$

stating that the 'radius' of the universe bears to the radius of the electron the ratio $N^{1/2} \sim 10^{40}$. This is one of the dimensionless numbers relating the fundamental constants.

The second relation follows when we take account of the relation between the Hubble's constant, the constant of gravitation G and the mean density ρ of matter in the universe. For the Friedmann model[5] with the deceleration parameter $q_0 = 1$, or for the steady state model with the C field[6],

$$\rho = 3H^2/4\pi G \tag{6}$$

Other models usually yield different coefficients of H^2/G on the right hand side, but they are of the same order as $3/4\pi$. Taking equation (6) to fix ideas, the mass of the matter in a sphere of radius R is around

$$4\pi R^3 \rho/3 \simeq c^3/HG \tag{7}$$

Observations of the Universe show that matter is largely made of equal numbers of electrons and protons at least in our neighbourhood. Taking M for the mass of a proton, the above relation gives an estimate of N:

$$NM \sim c^3/HG = c^2 R/G \tag{8}$$

If we now eliminate R between equations (5) and (8) we get

$$e^2/GMm \sim N^{1/2} \sim 10^{40} \tag{9}$$

The relations (5) and (9) are the core of the so-called Dirac relationships between fundamental constants. I now interpret these and discuss their astrophysical significance in the present picture by making the following points.

(1) Both relations express the overall dynamics of the Universe. The relation (5) arises from creation of charged leptons, the electrons and positrons in the cosmological framework. Although particles are created there is no overall loss of energy and momentum. Relation (8) may be looked upon either as an equipartition between the gravitational energy and the energy of expansion according to Einstein's equations or as a Machian relation determining the gravitational constant in terms of the matter content of the Universe[7,8].

(2) Although charge conservation is apparently violated when an electron is created, the violation is local, not global. The statistical fluctuation which requires the + sign in equation (4) for a given region is balanced by an opposite fluctuation which favours the creation of the opposite charge in another region. Thus we will tend to have electrons created in one region, positrons in another. Also the process is stable in the sense that the creation of too many electrons in a given region will produce a local contribution to A_4 which will soon cancel the cosmological contribution and thus control the process.

(3) Relation (6) owes its origin to a statistical fluctuation and hence is not exact. That is, it is not possible to fix the coefficient of $N^{1/2}$ on the right hand side which will make it exact although the coefficient will be of the order unity. The relation (8) is exact in any given cosmological model. (The

~ sign appears because I have not specified the model in my discussion.) If I use the present determinations of c, H and G, I find that $N^{1/2}\sim 7\times 10^{40}$ from equation (5) and $N^{1/2}\sim 1.3\times 10^{40}$ from equation (8)—a reasonably good agreement.

(4) It may be possible to turn equation (4) round and argue that it implies creation of leptons of different masses as H varies or as we take into account the variation in fluctuation. This raises the interesting possibility that the electron mass is not fixed all over the Universe. This avenue is worth exploring in view of the puzzles about the QSO redshifts unearthed by recent observations[9,10].

I thank Sir Fred Hoyle and Dr S. M. Chitre for illuminating discussions. I also acknowledge the award of a Jawaharlal Nehru Fellowship.

Production of Organic Molecules by Proton Irradiation

IN recent years there has been considerable interest in the production of complex organic molecules in primitive atmospheres. The emphasis of most of this work has been on mechanisms for prebiological synthesis of amino acids and related molecules, but the feasibility of producing organic chromophores which may account for the colours observed on planets and satellites in the outer Solar System by these same processes has become a topic of research effort in the past few years.

The early experiments[1-5] employed mixtures of methane and ammonia[4,5], sometimes with hydrogen[1] or water[2,3]; and indeed amino acids (in the experiments with H_2O) and related organic molecules have been produced. More recently[6-8], in attempts to simulate atmospheres likely to contain sulphur (those of Jupiter and primitive Earth), mixtures including hydrogen sulphide have been used. The results of these experiments were qualitatively similar to the non-sulphur ones, except for the production of free sulphur, alkyl sulphides and thio-amino acids. In one case involving a sulphur-free mixture a red polymeric material was reported[4], and this is considered a tentative candidate for the red colouring agent on Jupiter.

With the exception of the work of Palm and Calvin[2], in which energetic electrons were used, one of two types of energy sources was employed: electrical discharges[1,3-5] and ultraviolet light from a mercury lamp[6-8]. Electrical discharges may be initiated by strong atmospheric turbulence (similar to the familiar electrical storms) in the primitive atmospheres, and there is a significant amount of ultraviolet flux in the solar radiation. There is another source of energy, however, that is becoming increasingly worthy of consideration: energetic protons in the solar wind and in planetary radiation belts. Considerable attention has been given to the structure and composition of the radiation belts around Jupiter and the proton (and electron) flux is believed to be far from insignificant[9]. The satellites of the outer planets certainly are exposed to the solar wind, and two of these, Io and Titan, are unusually red[10]. Titan is especially interesting as it is known to possess an atmosphere of at least H_2 and CH_4 (ref. 11). Also, protons can bombard a planetary atmosphere directly from discharges in the radiation belts. It is possible, then, for proton bombardment to have a measurable effect on the organic chemistry of primitive planetary atmospheres.

The following preliminary experiments were carried out to investigate the effectiveness of proton irradiation for producing organic chromophores. The source of the 2 MeV protons used in the experiments was a model FN tandem Van de Graaff accelerator of the physics department at Stony Brook. The beams used ranged from 870 nA (5.44×10^{12} protons cm^{-2} s^{-1} over 1/3 cm diameter) to 220 nA (1.35×10^{12} protons cm^{-2} s^{-1}). Based on the nominal model[9] for the flux in Jupiter's radiation belt at six Jupiter radii from the planet (approximately the distance of Io), these beams correspond to 1.72 and 0.43 Earth years at Jupiter per second of exposure. Thus, for typical exposures of 3 and 6 h respectively, the total proton fluences are equivalent to those of 1.9×10^{5} yr and 9.2×10^{4} yr at Jupiter.

The gas cells used were hollow aluminium cylinders, each with a gas volume of approximately 125 cm³. Attached to both ends of each cell were infrasil quartz windows, enabling visual inspection of any reaction products and gas phase spectroscopy from 0.2 to 4 µm. A very thin pure nickel foil window was attached over a hole in the centre of each cell, perpendicular to the cylinder axis, to allow entry of the proton beam into the cell without loss of gas. The cells were evacuated to less than 10^{-3} mm Hg, filled with the appropriate gas mixtures (see below) and stored in a helium atmosphere to prevent contamination by air. The exposures were accomplished by placing the cells in a large target chamber, evacuating the chamber to 5×10^{-5} mm Hg, and running the beam into the cell for the desired length of time. The beam was stopped at the rear wall of the cell with approximately 1/2 MeV of the energy lost in the nickel window and 1 MeV deposited in the gas.

Five gas mixtures were used in this first series of experiments, none of which contained water. The first cell contained 50 cm³ CH_4 and 51 cm³ NH_3 at a total pressure of 615 mm Hg, and was exposed for 3 h at 870 nA. High resolution mass spectrometry of the gas phase indicated the presence of C_2H_2, C_2H_4, C_2H_6 and their methyl homologues, as well as C_4H_2 (diacetylene), CH_3CN, and residual CH_4 and NH_3. The orange-brown oily liquid produced was analysed by computer assisted gas chromatography-mass spectrometry[12,13], which indicated the presence of the expected alkyl hydrocarbons and alkyl amines. Some unexpected and interesting products were the tricyclic alkyl amines, hexamethylene tetramine ($C_6H_{12}N_4$) and its methyl and dimethyl homologues.

The second experiment was essentially the same as the first, except that the beam intensity was cut by a factor of four and the exposure was twice as long, resulting in the reduction of the total dose by half. The results of this run were similar to those of the first, except that the lower molecular weight molecules were enriched relative to the higher molecular weight ones. This indicates an 'evolutionary' sequence from low molecular weight to higher molecular weight, but further work will be done to confirm this.

A 1 : 1 : 1 mixture of $CH_4 : NH_3 : H_2S$ at a total pressure of 605 mm Hg was used in the third experiment. Before the irradiation, a thin white haze (NH_4SH ?) was observed inside the cells, but it was not seen after the exposure. This seems to be analogous to the white residue noticed by Sagan and Khare[8] in one of their experiments. The gas phase contained several simple hydrocarbons, saturated and unsaturated, along with CH_3CN and $(CH_3)_2S$. The gas chromatogram of the liquid, which was much yellower than in the previous cases, indicated the presence of a series of alkyl di and tri-sulphides, starting with $(CH_3)_2S_3$ and increasing in alkyl chain length, as deduced from the mass spectra of the various fractions. The yellow colour was found to be free polymeric sulphur, predominantly S_8. This is a very interesting result, as free sulphur (and subsequent ammonium polysulphides) have been proposed to account for the yellow and yellow-brown coloured layers on Jupiter[14]. Noticeably absent were the cyclic amines produced in the $CH_4 : NH_3$ experiments; the exposure here was a relatively short one and the result may reflect the relative reactivities of H_2S and NH_3.

In experiment four, a mixture of CH_4 with nitrogen was used instead of CH_4 and NH_3. The gas phase contained the same species as in the NH_3 cases but the liquid, similar in appearance to the others, contained a much larger proportion of alkyl amines relative to the cyclic amines.

The last cell, containing only CH_4, was run as a check on possible contributions of the apparatus itself to the final irradiation products. The gas phase again contained simple hydrocarbons, but also a trace of NH_3, caused by the nitrogen remaining in the cell after pumping and filling. The clear non-viscous liquid formed contained a mixture of higher molecular weight hydrocarbons, both saturated and unsaturated. No traces of any compounds containing nitrogen or sulphur were found.

It is obvious from the above results that energetic protons can be an effective energy source for the formation of complex molecules from simple ones. Subsequent decomposition of the products is not as serious a problem as might be believed as there are likely to be processes, such as convection and condensation, in the atmospheres for removing the molecules from the reactive zone, and there were found to be fair amounts of the liquids formed on the rear windows of the cells in the centres of the proton beams. In spite of the extreme energies involved (2 MeV) as compared to typical bond energies, there seems to be some sensitivity to different initial reactants, as different results were obtained for the $CH_4 : NH_3$ and CH_4N_2 mixtures, both containing only C, N and H. With the exception of the sulphide compounds none of the molecules that were identified are coloured; however, the colouring agents could be contained in the unresolvable fractions. It should be noted that no coloured compounds were produced in the pure CH_4 experiment; the presence of N or S seems to be necessary for their formation. Future experiments are being designed to probe this and other aspects relative to the outer Solar System colouring problem.

This research was supported by the National Aeronautics and Space Administration and the National Science Foundation. We thank the Nuclear Structure Laboratory of the Stony Brook Physics Department for providing assistance with the Van de Graaff accelerator. We also thank Mr Brian D. Andresen and Dr K. Biemann of the Chemistry Department at MIT for the mass spectrochemical results and their interpretation.

Particle Formation from NH_3-SO_2-H_2O-Air Gas Phase Reactions

RECENT articles on the formation of atmospheric aerosols from NH_3–SO_2–H_2O gas phase reactions[1,2] have considered only those products formed between the anhydrous gases to give 2:1 and 1:1 (NH_3:SO_2) compounds. I wish to draw attention to my work[3] on the reaction between these gases at partial vapour pressures in air of 50 to 500 N m^{-2}. Solid products were formed only in the presence of water vapour at 20° C. Analyses showed that the compounds formed were either ammonium sulphite (with excess NH_3) or ammonium pyrosulphite (with excess SO_2). Vapour pressure measurements at 0 to 23° C indicated that the extrapolated vapour pressures of NH_3 and SO_2 above the sulphite in dry air at −70° C would be about 1×10^{-4} and 5×10^{-5} N m^{-2} respectively. With 50% saturation of the air with water vapour at −70° C, however, these vapour pressures would be depressed to 8×10^{-6} and 4×10^{-6} N m^{-2} respectively, that is, to concentrations approximately equal to those reported for the 2:1 compound. The partial vapour pressures of the pyrosulphite under similar conditions would be 3.3×10^{-5} N m^{-2} for both gases. At −52° C the vapour pressures of these gases in dry air would be identical for both the 2:1 compound and ammonium sulphite.

It seems, therefore, that there will be competition between the formation of the 2:1 compound and ammonium sulphite in the stratosphere except under completely anhydrous conditions.

Thorium Determination in Glasses using Fission Track Technique

WE have applied the fission track technique to the determination of thorium in glasses. Neutron-induced fission occurs for thorium and uranium, the isotopes ^{232}Th, ^{235}U and ^{238}U fissioning with fast neutrons, and ^{235}U with thermal neutrons. Two irradiations are performed. The first irradiation is with predominantly thermal neutrons for determination of the uranium content (comparing to a standard and knowing the isotopic ratio of uranium) and the second irradiation is with predominantly fast neutrons which gives the uranium and thorium contents combined. The 'track excess' from the second irradiation, when the unknown is again compared to a uranium standard, is attributed to thorium fission.

Consideration of several factors is important for evaluation of a standard. Knowledge of (1) the fission cross sections for the various isotopes as a function of neutron energy[1], (2) the neutron energy spectrum for the reactor facility[2] and (3) the isotopic concentrations enables the percentage of tracks contributed by any one isotope to be calculated. The total number of fissions produced ($\Sigma_\tau \Phi_\tau$) from a mixed neutron energy spectrum, where the fast neutron energy spectrum is taken between 1 and 10 MeV and the thermal neutron induced fission of only ^{235}U is considered, is given by

$$\Sigma_\tau \Phi_\tau = N^{232}\int_1^{10}\sigma_f^{232}(E)\,\phi_f(E)\,dE + N^{238}\int_1^{10}\sigma_f^{238}(E)\,\phi_f(E)\,dE + N^{235}\int_1^{10}\sigma_f^{235}(E)\phi_f(E)dE + N^{235}\sigma_t^{235}\phi_t$$

where N is the atom density of an isotope; $\sigma_f(E)$, the fast fission cross section of a specific isotope as a function of energy; $\phi_f(E)$, fast neutron flux as a function of energy; dE, energy interval; σ_t, the cross section for thermal fission of ^{235}U; and ϕ_t, the thermal neutron flux.

Table 1 Comparison of Fission Tracks and Other Techniques for Determination of Thorium

* * Using α irradiation, see ref. 9.

Therefore, from this equation and with our irradiation conditions with predominantly fast neutrons[3], and for a material containing the natural isotopic ratio of uranium (^{238}U/^{235}U = 137.8), a Th/U ratio of 1,000 would mean that 80% of the tracks are from Th fission; a Th/U ratio of 4 means that only about 3% of the tracks are from Th fission. This low percentage approaches the limit of error imposed by track counting statistics. In our experiments, the standard used was NBS SRM 614 (ref. 4) where Th/U = 0.906 and ^{235}U = 0.2792 atomic % abundant. Even with the depleted ^{235}U, this served well as a uranium standard in the fast neutron facility and only 1.5% of the tracks observed in the detector were from thorium fission.

The samples and standard were mounted in epoxy and polished; an external detector was then affixed. Mica was preferred for use as an external detector because the temperatures attained during the second irradiation with fast neutrons would partially anneal the tracks in a plastic detector.

The glasses used in this study consisted of five lanthanum-based glasses (~48% La$_2$O$_3$) used as thorium standards by the US Army Night Vision Laboratory at Fort Belvoir, Virginia. Thorium glass T-1 described by Schreurs and others[5], and glass K2a described by Lovering (personal communication). The fission track results compared to Th determination by other methods (where data are available) are shown in Table 1. It was assumed that the range of fission fragments is proportional to the density of the material through which they pass[6]. Therefore, an additional correction was made for the differences in densities of the standard glass and the unknown glasses. As expected, the error increases with a lower Th/U ratio. For glass K2a with a Th/U ratio of ~1, our result was 20% greater than the value reported by Lovering. The fission of ^{235}U is still a major contributing factor, however, and by reducing this contribution by cadmium shielding, for example, or in a facility with a greater fast flux component, the error would be reduced.

This particular technique can easily be adapted for Th determination in minerals where the natural U isotopic ratio can be assumed, and would permit data to be acquired that would be more accurate than previously obtained by a neutron induced fission track method[7]. In addition, using this fission track technique for determining thorium and uranium avoids the uncertainties which result from beam current heating of the sample or observation efficiency differences when either α or other high energy particles are used to induce fission of thorium[8,9].

Part of this work was carried out under the supervision of the US Army's ECOM Night Vision Laboratory and TROSCOM Mobility Equipment Research and Development Center. G. M. R. is a National Research Council Postdoctoral Associate of the National Bureau of Standards.

NaOH Etch of Fission Tracks in a Soda-Lime-Silica Glass

IT is generally known that fission tracks intersecting the surface of man-made soda-lime-silica glasses can be etched with HF at room temperature[1,2]. In this technique the acid attacks the tracks preferentially so that they become visible in the microscope before the glass itself is destroyed. An NaOH etch at 60° C has been reported for phosphate glasses[3].

I wish to report a glass which I believe to be a soda-lime-silica glass that is etched by NaOH rather than HF. The material consists of numerous glass beads of a recognisable type known as 'trade wind beads' found in archaeological sites of the past millennium in eastern and southern Africa. They are consistently similar in appearance and chemical composition. Their composition is partly reported in Table 1 and abundant further information is available elsewhere[4].

Table 1 Partial Composition of 'Trade Wind Beads'

Element	Concentration	Method	No. of samples
Na	15.0±1.5%	NAA	133
Ca	4.4±1.9%	NAA	133
K	2.3±1.4%	NAA	133
Pb	~0.01–7.0%	XRF	~200
P	~0.1%	ES	2
U	112±55 p.p.m.	NAA	133
(SiO_2	~56%	XRF	1)

NAA, neutron activation analysis; XRF, X-ray fluorescence analysis; ES, emission spectroscopic analysis.

The beads are thought to contain fossil fission tracks useful for dating. In an attempt to etch such tracks, experiments were carried out on artificially produced fission tracks in 'trade wind beads'. HF at various concentrations at room temperature attacked the glass without etching the tracks preferentially. Successful etching was accomplished by refluxing for 7 min in NaOH. The reflux solution was made by dissolving 12 g NaOH in 16 g water.

The dating research was supported by the Wenner-Gren Foundation for Anthropological Research and was carried out in the Lawrence Berkeley Laboratory.

BIOLOGICAL SCIENCES

Proximal Myopathy induced by 5-HT-Imipramine simulates Duchenne Dystrophy

IT has recently been observed that patients with Duchenne muscular dystrophy (DMD) have a significant defect in the uptake of serotonin (5-HT) into platelets[1], raising the possibility that a defect in the metabolism of biogenic amines may be important in the pathogenesis of the skeletal muscle lesions of this disorder. If monoamines such as 5-HT or norepinephrine (NE) which are dependent on the intracellular enzyme, monoamine oxidase (MAO), have a diminished ability to reach this site of metabolism, increased tissue levels of these compounds could result and produce skeletal muscle damage. The effect of such a defect would be enhanced in skeletal muscle as catechol-O-methyltransferase, the alternative pathway for metabolism of biogenic amines, is absent from this tissue[2]. Support for this hypothesis of skeletal muscle damage is found in the observation that skeletal muscle from biopsies of Duchenne dystrophy patients has shown the presence of an abnormal intrafibrillar fluorescence (Falck-Hillarp technique) presumed to be a monoamine-like substance[3]. Furthermore, injection of the MAO inhibitor, pargyline, results in a myopathy with evidence for accumulation of monoamines[4]. The pargyline induced myopathy, however, has serious limitations as a model for Duchenne dystrophy, as the lesions are limited to the soleus muscle and, furthermore, MAO activity has been found to be normal in patients with DMD (ref. 1).

Here we report the findings of an experimental myopathy using 5-HT in combination with imipramine, a pharmacological agent blocking uptake of biogenic amines into platelets[5] and thereby producing a defect in biogenic amine metabolism closely simulating that observed in patients with DMD. The results of this study are extremely important in two ways. First, the very typical early and mid-stage histological lesions of DMD were reproduced and, second, this study represents the first demonstration of an experimental animal model with skeletal muscle lesions predominating in the proximal musculature, as is so characteristic of the clinical disease.

Fifty male Osborne-Mendel and Sprague-Dawley rats weighing 135 to 150 g were used. Fresh frozen sections of soleus, gastrocnemius, anterior tibialis, extensor digitorum longus, quadriceps, iliopsoas and deltoid muscles were stained by modified trichrome, haematoxylin and eosin, reduced nicotinamide dinucleotide-tetrazolium reductase and myofibrillar adenosine triphosphatase[6]. At the beginning of the study all rats were injected intraperitoneally with imipramine, 10 mg kg^{-1}, for 3 d. On the fourth day the animals received 5-HT, i.p., 100 mg kg^{-1}. Each week two rats were killed 4 d after the injection of 5-HT, the remaining rats being injected with the same dosage schedule for a total of 11 weeks.

Skeletal muscle lesions were seen in all rats examined and increased in severity as the number of injections in each rat increased. The distribution of the histological lesions in these animals was quite striking as the lesions were very severe in the quadriceps, moderately severe in iliopsoas and occasionally present in the soleus. In the gastrocnemius, anterior tibialis and extensor digitorum longus, only rare skeletal muscle pathology was encountered. The earliest lesions consisted of necrosis and phagocytosis and regeneration of individual muscle fibres or small groups of muscle fibres surrounded by a field of normal muscle (Figs 1 and 2). This is identical to the early lesions of DMD (ref. 7). In animals receiving multiple injections, the lesions showed signs of chronicity manifested by a marked variability in fibre size, internal sarcolemmal nuclei and proliferation of connective tissue surrounding individual muscle fibres (Fig. 3). This is characteristic of the mid-stage histological lesions of DMD (ref. 7). No abnormalities were seen in the intramuscular nerves and the intramuscular arteries showed no signs of occlusion, although, rarely, they were surrounded by a small round cell infiltrate, similar to that described in DMD (ref. 8).

Control animals included those injected i.p. with imipramine 10 mg kg^{-1} as above but without follow-up injections of 5-HT. Another group of animals was injected i.p. daily for 7 d with imipramine, 25 and 50 mg kg^{-1}. A third group of controls included those injected with single doses of 5-HT, 100 mg kg^{-1}. Only rare scattered fibres undergoing necrosis and phagocytosis were seen in the animals injected with imipramine, 50 mg kg^{-1} and 5-HT, 100 mg kg^{-1}.

We feel that this animal model of Duchenne dystrophy is extremely important because not only have the highly characteristic histological skeletal muscle lesions been reproduced but of possibly greater significance is the fact that the proximal muscles were found to be the principal site of lesion predilection. These abnormalities were the result of injections of 5-HT in combination with a pharmacological agent, imipramine, which reproduces an abnormality in biogenic amine metabolism similar to that found in patients with DMD. This study adds significance to the previously described transport defect of 5-HT (ref. 1) in DMD and opens many new avenues of investigation in a disease which has remained an enigma since its description. Furthermore, this 5-HT-imipramine induced myopathy provides a suitable animal model for future study which is superior to others previously described using arterial embolisation[8] or aortic ligation in combination with 5-HT or NE (ref. 7). These models, requiring surgical manipulation, failed to show a predilection of skeletal muscle pathology in a proximal distribution.

The pathogenesis of the proximal muscle lesions produced in this animal model remains to be elucidated. It is unclear at this time whether the lesions are the result of functional ischaemia to the skeletal muscle or are the result of direct myotoxicity. It also remains to be established whether or not these lesions are dependent on an intact nerve supply as are those induced by the MAO inhibitor, pargyline. Studies are currently under way to answer these and other questions.

Dose Dependence of Antigen Binding to B and T Lymphocytes

Specific precursor cells, as lymphocytes binding ^{125}I-labelled antigens, can be detected by autoradiography (see refs 1 to 3 for reviews). Classification of such antigen binding cells (ABC) into T and B cells gave equivocal results. Cell populations enriched in B cells (by treatment with anti-θ serum and complement) or in T cells (by passage through anti-immunoglobulin columns) indicated that some of the ABC were indeed T cells, but that they bound far less antigen than did B cells[4–7]. Using a direct approach by treating lymphocytes in sequence with ^{125}I-antigen (*Maia squinado* haemocyanin: MSH, or bovine serum albumin) followed by fluorochrome-labelled anti-immunoglobulin, anti-B, anti-T, or anti-θ reagents, Lamelin *et al.*[8] did not detect significant numbers of T ABC, while Roelants *et al.*[9] using the same antigen MSH and also the heavily iodinated (>50 atoms I per molecule) (Tyr, Glu)-Ala-Lys synthetic polypeptide (TIGAL) found that 20–30% of the ABC in primed mice were T lymphocytes and that they bound as much antigen as B ABC. Joint experiments (J. P. Lamelin and G. E. Roelants, unpublished) showed that this discrepancy was due to the hundred-fold lower concentration of antigen used by Lamelin *et al.* The influence of antigenic concentration on the binding by B and T cells has been systematically investigated, with the following results.

Antigen binding, with detection of immunoglobulin or θ surface markers on the same cell, has been described[9]. Briefly, 20×10^6 spleen or lymph node cells were mixed with various amounts of ^{125}I-TIGAL (20 to 300 μCi μg^{-1}) in a final volume of 0.4 ml ice cold Eagle's Minimal Essential Medium, 10% foetal calf serum (FCS), 1.5 mM NaN$_3$. In preliminary experiments cells were also exposed to antigen (2.5 μg ml^{-1}) at higher temperatures (23° C and 37° C) which only had a minimal effect on ABC frequency (10–20% increase of both B and T ABC). Further experiments were always carried out in the cold. After 45 min the cells were washed of excess antigen, incubated with either rhodamine-conjugated rabbit anti-mouse Ig or AKR anti-θ C3H immunoglobulin, washed, smeared on gelatine-coated slides and fixed for 5 min in absolute ethanol. Autoradiography was performed using Ilford K5 emulsion. The cells were observed under phase contrast at 100×6.3-fold magnification with Leitz Orthoplan microscopes equipped with Osram HBO-200 mercury vapour lamps and Opak-Fluor vertical illuminators (E. Leitz GmbH, Wetzlar, Germany). B lymphocytes were identified as immunoglobulin positive or θ negative and T lymphocytes as immunoglobulin negative or θ positive. The validity of this classification has been discussed in detail[9].

Lymph nodes or spleen cells from unprimed C3H/He mice (either sex, 2.5 to 5-month-old, Roche, Füllinsdorf, Switzerland) or spleen cells from primed mice (100 μg TIGAL precipitated with alum and 10^9 killed *Bordetella pertussis* intraperitoneally 4 month previously) showed a plateau in the number of B and T ABC at antigen concentrations of about 2 μg ml^{-1}. Cells pooled from 4–6 mice were used for each experiment. In accordance with reported results[9] at the plateau the overall frequency of ABC 4 month after priming was not very different from that of unprimed mice (400×10^{-5} to 700×10^{-5}). Figure 1 shows, for example, the ABC frequency of normal lymph node cells exposed to concentrations of TIGAL ranging from 0.5 to 4 μg ml^{-1}. Earlier experiments over the range of 2 to 64 μg ml^{-1}, at two-fold steps, did not cover the lower limit of the curve but showed that the plateau extended over all concentrations above 2 μg ml^{-1}, so the rise at 4 μg in Fig. 1 was not significant.

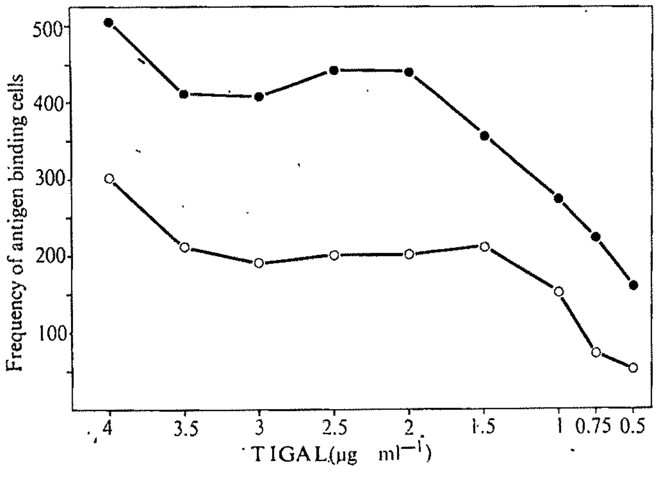

Fig. 1 Frequency of antigen binding B (●, $\times 10^{-5}$) and T (○, $\times 10^{-6}$) cells in a normal lymph node cell population at various concentrations of antigen (50,000 to 100,000 lymphocytes were examined per group).

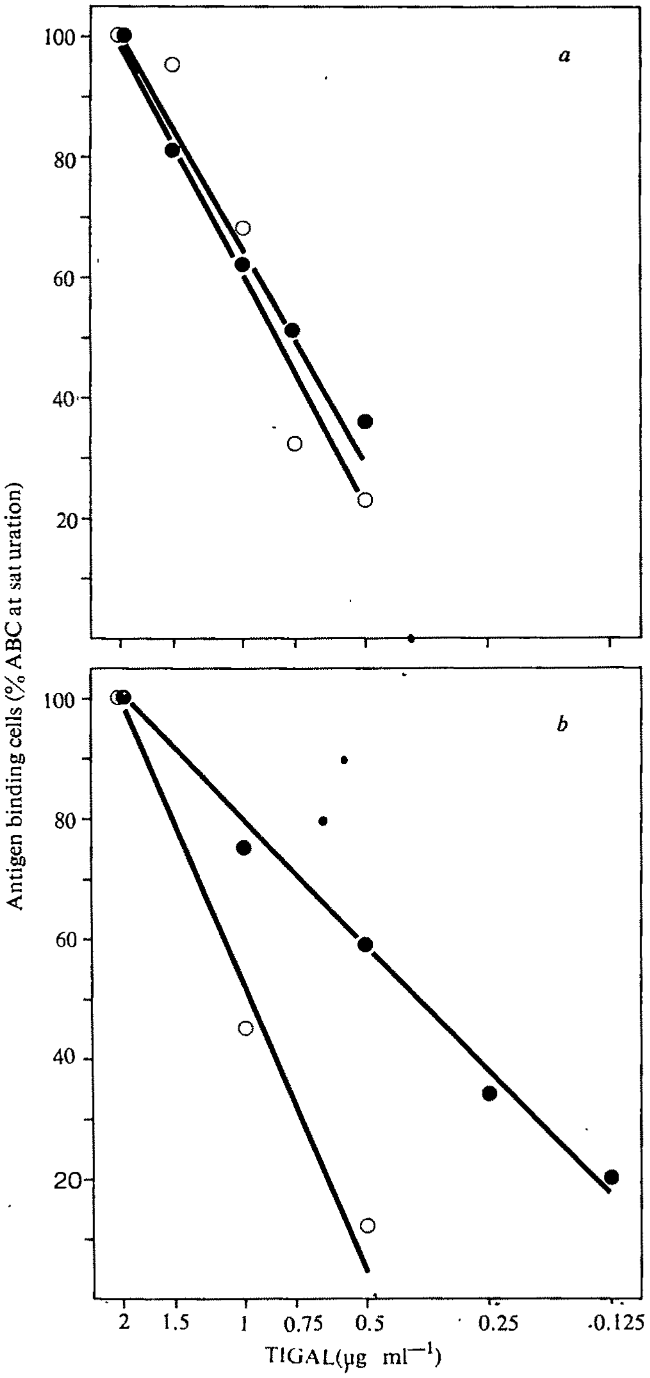

Fig. 2 Titration of, *a*, normal and, *b*, TIGAL-primed antigen binding cells at antigen doses below the plateau level (50,000 to 100,000 lymphocytes were examined per group). ●—●, B; ○—○, T lymphocytes.

Figure 2 shows the regression of B and T ABC on antigen concentrations below the saturation level. For unprimed cells the slopes are similar for B and T ABC; the slope of B ABC decreases after priming. This observation, in agreement with those of Möller and co-workers[10,11] using hapten inhibition of rosette formation, indicates that the avidity of both T and B rosette-forming cells is similar in unprimed animals, whereas after priming the avidity of B cells is increased, but that of T cells remains unchanged.

The degree of labelling, as indicated by the number of grains, was similar for T and B cells at a TIGAL concentration of about 2 μg ml^{-1}. Varying the concentration of antigen had a strikingly different effect on the degree of labelling of B or T ABC. As exemplified in Fig. 3 with a primed spleen cell population, the proportion of heavily

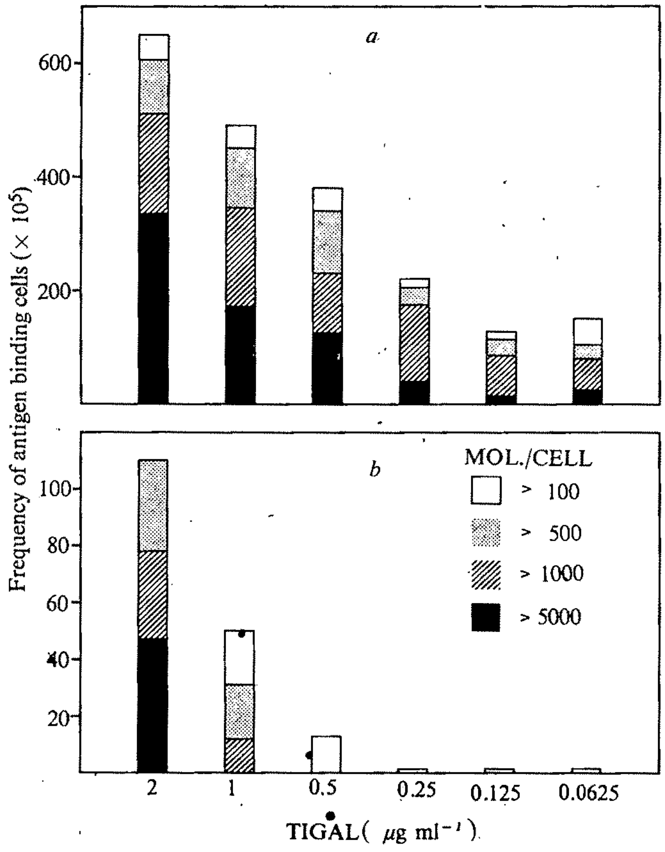

Fig. 3 Degree of labelling of TIGAL-primed antigen binding cells at various antigen doses. The ABC were distributed into four classes depending on their degree of labelling expressed as molecules per cell (see inset legend). *a*, B cells; *b*, T cells.

labelled B cells decreased when the concentrations of antigen were lowered, but even at the lowest concentrations used (0.0625 μg ml^{-1}) some heavily labelled B cells were still present. In sharp contrast all the heavily labelled T cells were lost by a mere two-fold dilution from the plateau (1 μg ml^{-1}). Unprimed cells behaved the same way, even though the overall proportion of T and B cells labelled was similar at different concentrations of antigen (see Fig. 2). Since the number of B ABC did not increase between 4 and 64 μg TIGAL ml^{-1}, some B cells were saturated with as little as 100 molecules of antigen. T cells seemed to be more homogeneous in this respect since they all become heavily labelled at high concentrations of TIGAL. Whether all T ABC bind a maximal amount of antigen (about 50,000 molecules) at saturation cannot be decided from these experiments, due to overlapping and confluent grains above 500 per cell.

These observations render it mandatory to establish binding curves over a wide range of concentrations. Without this tedious process, no valid information about the number of B and especially T ABC can be obtained. Hämmerling *et al.*[6,7] studying ABC for (T,G)-A--L (antigenically different from TIGAL) used concentrations of antigen between 0.5 and 1 μg ml^{-1} and detected only T ABC binding less than 500 molecules of antigen. Even with the far more potent immunogen TIGAL used here no heavily labelled T ABC are detected at those antigen concentrations. Binding curves for (T,G)-A--L are being determined and preliminary results indicate that a plateau is reached only for antigen concentrations as high as 25 μg ml^{-1}.

As shown by the saturation experiments, T cells possess a number of receptors for antigen comparable to that of B cells. The effect of antigen dilution on the distribution of label density is, however, far more pronounced for T than for B ABC, indicating that the average avidity for antigen is both lower and more uniform. Whether this is due to an inherent property of the receptor or is due to the nature of the T cell membrane remains to be investigated. The fact that even primed B ABC have widely varying numbers of receptors suggests that the high avidity of primed B ABC may be due not only to selection of cells with higher affinity receptors but also to 'maturation' of cells acquiring a larger number of receptors. Neither selection nor maturation could be discovered for T ABC.

The titration curves of this study do not argue either for or against the immunoglobulin nature of the T-cell receptor. Experiments approaching this problem in a direct way are presented in a companion paper[12].

We thank Drs R. E. Cone, S. Fazekas de St Groth, F. Loor and M. Nabholz for discussions.

Active Synthesis of Immunoglobulin Receptors for Antigen by T Lymphocytes

WHEN antigen binding cells (ABC) were studied by combined autoradiography and immunofluorescence it was found that antigen binding to both B and T ABC could be inhibited by anti-immunoglobulin (anti-Ig) reagents[1]. Moreover, receptors for antigen could be redistributed in caps in a similar way for B and T ABC using non-inhibiting doses of anti-Ig reagents[1]. Since membrane components are known to redistribute independently of each other[2–5] it was concluded from the inhibition and capping experiments that the receptor for antigen on T lymphocytes was immunoglobulin. The fact that T ABC are always a small minority of the total T cell population argues against the possibility that their receptors are passively acquired as cytophilic antibody. We present evidence confirming that T cells have receptors for antigen which are immunoglobulins and showing, in addition, that they are actively synthesised by the cells carrying them.

Both the redistribution of surface immunoglobulin after interaction with anti-Ig reagents, and the combined autoradiographic immunofluorescent technique of estimating antigen binding and demonstrating immunoglobulin or θ surface markers on the same cell, have been described previously[1,3]. Our present experimental scheme is set out in Fig. 1. Lymph node cells (80 to 85% T cells) from four to six unprimed C3H/He mice per experiment (either sex, 2.5 to 5 months old, Roche, Füllinsdorf, Switzerland) were exposed to a polyvalent rabbit-anti-mouse immunoglobulin reagent labelled with fluorescein isothiocyanate (FITC-RIgG-α-MIgG) and incubated under conditions allowing polar redistribution (capping) and endocytosis of cytoplasmic membrane immunoglobulin. In some experiments a second layer of unlabelled sheep anti-rabbit L chain reagent (Sser-α-RL)[3] was added to ensure complete clearing of surface Ig. After various incubation times, samples of cells were taken and exposed, under non-capping conditions, to radioactively labelled heavily iodinated (Tyr, Glu)-Ala--Lys synthetic polypeptide (> 50 atoms I per molecule) (^{125}I-TIGAL) at saturating doses for detection of ABC[6]. The cells were then divided into two parts under non-capping conditions: one was stained with rabbit anti-mouse immunoglobulin (IgG) reagent labelled with tetramethylrhodamine isothiocyanate (TRITC-RIgG-α-MIgG)[3], the other with rhodamine-labelled AKR anti-θ-C3H IgG (TRITC-anti-θ)[1,7]. As a control, cells were first incubated with a rabbit IgG antibody directed against tobacco mosaic virus (FITC-RIgG-α-TMV)[3] instead of FITC-RIgG-α-MIgG; subsequently these cells went through the same steps as the experimental group.

Fig. 1 Basic experimental procedure.

Characterisation of the various reagents used has been described[1,3,7]. The main specificity controls were as follows. TRITC–anti-θ stains the expected proportion of C3H mouse lymph node, spleen or thymus lymphocytes but stains neither AKR mouse thymocytes nor nude mouse spleen cells. Its capacity to stain C3H thymocytes or spleen cells is completely removed by absorption with C3H mouse brain. The capacity of TRITC-RIgG-α-MIgG to stain B cells, to block or to induce polar redistribution of receptors for antigen on T and B cells is removed by absorption with unsolubilised IgG myeloma. We used the FITC conjugate of the same RIgG-α-MIgG preparation. The capacity of both TRITC and FITC-RIgG-α-MIgG to stain B lymphocytes is absorbed by passage on electrophoretically purified IgG from normal mouse serum coupled to Sepharose. Anti-lymphocyte serum does not inhibit antigen binding to B and T lymphocytes and does not redistribute in polar caps, indicating that the activity of our reagents is not simply due to anti-membrane contamination.

The basic experiment was repeated five times, always using normal lymph node cells to exclude cytophilic anti-TIGAL antibody. The findings were reproducible and a sample is given in Fig. 2 (see also Table 1).

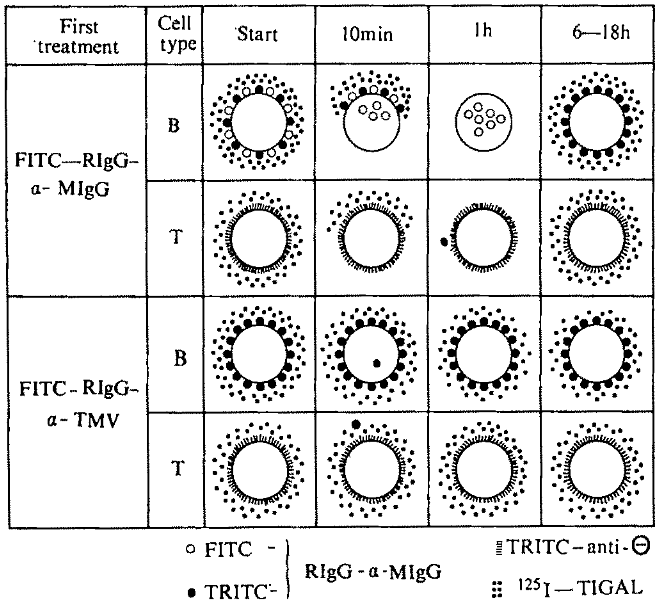

Fig. 2 Capping and resynthesis of immunoglobulin receptors for antigen on T and B lymphocytes. For experimental protocol see Fig. 1 and text.

FITC-RIgG-α-MIgG induced capping and endocytosis of cell surface Ig as detected on B cells by fluorescence microscopy (Leitz Orthoplan microscopes equipped with Osram HBO-200 mercury vapour lamps and Opak-Fluor vertical illuminators; 100 × 6.3 or 100 × 1.25 × 6.3 magnifications[1,3]). Endocytosis was complete in about 1 h. At this point the cells were no longer stained by the subsequent treatment with TRITC-RIg-Gα-MIgG. As described before[1], during the capping treatment both B and T ABC at first showed ^{125}I-TIGAL radioactive grains in caps, superimposed on the Ig caps in the case of B ABC, but after about 1 h, neither B nor T ABC were detected. In three experiments, ABC and surface immunoglobulin started to reappear about 3 h after capping and the receptor resynthesis was complete in about 6 h, in agreement with earlier observations[3]. In two experiments, however, complete resynthesis took 12–18 h. It is noteworthy that T ABC in each case followed the same kinetics of disappearance and reappearance as B ABC.

It would seem far-fetched that, in a population of normal lymph node cells, rare T cells (frequency 23–43 × 10^{-5}) would bear at their surface enough passively adsorbed antibody to bind up to 50,000 molecules of TIGAL and even less likely that during the *in vitro* incubation after capping, TIGAL-specific B cells (frequency 54 × 10^{-5} to 108 × 10^{-5}) would have secreted enough anti-TIGAL antibody which would bind only to those rare T ABC to bring their number back to their initial level. It could still be argued that the antigen-specific T-cell receptors were associated with some passively acquired Ig, were co-capped with it by the anti-Ig treatment, and were

Table 1 Active Synthesis of Ig Receptors for Antigen by B and T Lymphocytes

later resynthesised. Although there is no precedent for such co-capping, we sought formal proof that the antigen binding receptors which reappeared on B and T ABC were indeed immunoglobulin.

Two experiments were therefore extended by taking samples of cells known to have capped and resynthesised and exposing these cells once again to FITC-RIgG-α-MIgG. They were then, as before, put in capping conditions and later exposed, under non-capping conditions, to ^{125}I-TIGAL, followed by TRITC-RIgG-α-MIgG. Results of one complete experiment are given in Table 1: receptors for antigen on both B and T ABC which had been resynthesised after capping were cleared again by a second treatment with anti-Ig reagents. Samples of cells were examined before the total clearance of surface receptors by the second FITC-RIgG-α-MIgG treatment and showed that this clearance was also due to capping.

These experiments demonstrate the active synthesis of immunoglobulin receptors for antigen by T lymphocytes. The nature of these receptors in terms of known Ig classes remains to be investigated. It is perplexing that these receptors are not readily visualised using conventional fluorescent anti-Ig reagents. This may be due to their location in the T cell membrane; for instance, only a small part of the Ig receptor molecule(s) may be accessible to rabbit anti-M IgG antibody. These parts may, however, be detectable by antibody present in anti-M Ig antisera raised in chicken (F. L., J. R. L. Pink and L. Du Pasquier, manuscript in preparation).

Increase in Kallikrein Excretion during the Natriuresis produced by Arterial Infusion of Substance P

SUBSTANCE P was discovered by von Euler and Gaddum in 1931 in extracts of brain and small intestine[1] and its distribution and effects have recently been reviewed[2]. Its structure has been identified[3] and the undecapeptide has recently been synthesised[4]. Substance P is a potent stimulator of salivary secretion[5]; stimulation of the chorda-lingual nerve leads to increases in the production of saliva and blood flow through the salivary gland and is associated with the depletion of glandular kallikrein[6]. The presence of atropine blocks secretion but does not affect the increase in blood flow[7] or kallikrein depletion[6]. In homogenised nervous tissue substance P is located in the fraction containing the synaptic vesicles[8].

It seemed from these findings that substance P at the nerve endings might be released and lead to the activation or release of kallikrein. Kallikrein has been demonstrated in a variety of tissues which produce a liquid secretion such as salivary glands[9], small intestine[10], pancreas[11], sweat glands[12] and kidneys[13]. Urinary kallikrein resembles renal kallikrein[14] and differs from plasma kallikrein[15]. In severe renal failure urinary kallikrein excretion is very high which also supports the view that it is of renal origin and not filtered from plasma[16]. Kallikrein excretion is closely related to sodium excretion in a variety of circumstances[16–18]. Nevertheless increased sodium excretion also occurs without an associated increase in kallikrein excretion when there is a sharp fall in mineralocorticoid activity. These two processes related to sodium excretion are clearly differentiated by the Na/K ratio in the urine[19].

If 'substance P-inergic' nerves exist and promote the release of kallikrein, it might be expected that substance P infusion into the renal artery would lead to the release of kallikrein and a natriuresis. This has been tested in greyhound dogs under pentobarbital anaesthesia. Both ureters were catheterised and 0.9% saline was infused into the left renal artery at 1 ml min^{-1}. After several 10 min control collections of urine the infusion was changed to synthetic substance P (Beckman) in saline for three periods, then back to saline alone. Urinary sodium was measured by flame photometry. Kallikrein was assayed by determining the esterase activity of the enzyme in releasing tritiated methanol from a synthetic labelled substrate (*p*-tosyl-L-arginine-^{3}H-methyl ester)[20]. Pancreatic kallikrein (Bayer) was used as a standard in the assay and the results are given in esterase units, which are defined in Table 1.

In thirteen experiments on five dogs doses of 1, 10 and 100 ng substance P min^{-1} were used, equivalent to 30–4,300 pg kg^{-1} min^{-1}. The changes in sodium and kallikrein excretion, calculated as the differences between excretion in the experimental periods and the mean of the control periods immediately preceding and following the peptide infusion, are shown in the

Table 1 Increases in Sodium and Kallikrein Excretion in Response to Arterial Infusions of Substance P

Substance P dose (ng min^{-1})	Sodium excretion (μEq min^{-1})		*P*	Kallikrein excretion (mEU min^{-1})		*P*
	Control	Increase		Control	Increase

100	55.0±14.27 n (8)	128.9±19.16 (12)	<0.001	443±123 (8)	192±46 (12)	<0.005

Means ±s.e.
n, Number of control or experimental periods (see text).
P is derived from a *t* test on paired values.
EU, Esterase unit, equivalent to the hydrolysis of 4.8 μmol *p*-tosyl-L-arginine-methyl ester per h at *p*H 8.5 and 37° C.

table. The mean increases in sodium excretion were significant at each of the three doses. Mean kallikrein excretion increased at 1 ng min^{-1} though not significantly, but at 10 and 100 ng min^{-1} the increases were highly significant ($P<0.005$). The changes in excretion of sodium and kallikrein, when correlated with the logarithm of the dose of substance P infused, showed a highly significant correlation: $r=0.756$; $P<0.01$ for sodium and $r=0.735$; $P<0.01$ for kallikrein.

The data on sodium excretion place substance P amongst the most potent natriuretic substances so far described. Its threshold dose (around 1.0 ng min^{-1}) is less than, and its maximal effect greater than, those of the prostaglandins E_1, E_2 and A_1 found in comparable studies on dogs[21–23]. The concentration in the renal artery plasma which was natriuretic was approximately 0.1–1.0 ng ml^{-1} which is well below the limit of detection of a recent radioimmunoassay for substance P (ref. 24).

A variety of vasodilators are natriuretic when infused into the renal artery, for example bradykinin[25], lysyl-bradykinin[26], dopamine[27] and acetylcholine[28]. Substance P is also a vasodilator[29]. Since substance P stimulates natriuresis, salivary secretion and nasal secretion and all these processes are related to an increase in kallikrein activity, it is possible that the vasodilator action is dependent upon the release of kallikrein. There is strong evidence that urinary kallikrein originates from the kidney[14–16], being located principally in the cortex[30].

In view of the similarity between nervous stimulation and substance P infusion in their effects on stimulation of saliva flow and the related release of kallikrein and vasodilation in the salivary gland[5–7], the release of kallikrein from the kidney might be a direct effect of the substance P.

The effect of substance P on the kidney is a further example of the relation which has been shown between kallikrein excretion and sodium excretion[16–19] but in this case there is no associated expansion of body fluid volumes. The bradykinin released by kallikrein is known not only to be a vasodilator but also to increase vascular permeability. The natriuresis produced by the intra-renal release of kallikrein may be effected by vasodilator and permeability effects on the renal vasculature and tubules.

Androgen-induced Sexual Differentiation of the Brain is Blocked by Inhibitors of DNA and RNA Synthesis

SEXUAL differentiation of gonadotrophin secretion in the rat is known to occur during the early postnatal period under the action of testicular androgens[1,2]. Animals of either sex if exposed to androgen during this critical period develop the typical male pattern of gonadotrophin secretion after puberty with failure of ovulation, small polyfollicular ovaries lacking corpora lutea and a constant cornified vaginal epithelium. Several studies have localised this effect to the brain[3,4] and more particularly to the anterior hypothalamus[5], but very little is yet known of the mechanism of this effect.

What is known of the action of androgens and oestrogens on their peripheral target tissues would suggest that the steroid enters the cell, is rapidly transported to the nucleus and, by an action on the genome, induces specific RNA and protein synthesis and later DNA synthesis and cell division[6–8]. Inhibitors of these processes might therefore be expected to provide some protection against the masculinising effects of androgen in the neonatal female rat. Attempts to achieve this with inhibitors of RNA and protein synthesis by Gorski and coworkers[9,10] have so far produced only partial and/or temporary inhibition of the action of a low dose of androgen (30 μg of testosterone propionate, TP). Barnea and Lindner[11] gave direct intracerebral injections of DNA and protein synthesis inhibitors but failed to achieve any protection against the effects of 100 μg of TP. We therefore tested the effects of a variety of inhibitors of DNA, RNA and protein synthesis combined with three different dosages of TP and have obtained evidence of permanent and, in some cases, almost complete protection against the masculinising effects of the androgen.

Female Wistar rats were treated when 4 d old with 30, 80 or 200 μg of TP s.c. in oil and the inhibitors were administered by the same route in divided doses together with and 6 h after the TP. The inhibitors used were: hydroxyurea (OH-U), an inhibitor of DNA synthesis with no effect on overall RNA synthesis[12]; α-amanitin (AMAN), an inhibitor of nucleoplasmic or messenger-precursor RNA synthesis[13]; actinomycin D (ACT.D), at the low doses used in this study, a selective inhibitor of nucleolar or ribosomal RNA synthesis[14]; puromycin (PURO), a general inhibitor of protein synthesis, and fluorouracil (FU) which induces errors of translation and the synthesis of non-functional proteins. Cycloheximide was also tested at several doses but found to be too toxic for use in neonatal rats (compare refs 10 and 11). The progress of masculinisation was followed by daily vaginal smears for at least 3 weeks prior to death at 80 to 110 d. Animals were assessed as acyclic if they showed at least 8 consecutive d of cornified smears. The ovaries were removed (where possible on the day of oestrus) and were weighed and examined for the presence of recent (functional) corpora lutea and the oviducts were examined for the presence of eggs.

Table 1 shows the results of a low (30 μg) dose of TP combined with the maximum dose of each inhibitor compatible with survival to adulthood. This dose of TP did not induce full masculinisation at 80 d of age; at this stage 20% of the animals still had functional corpora lutea and 30% showed irregular vaginal oestrous cycles. Nevertheless, the inhibitors OH-U and AMAN were capable of preventing this degree of masculinisation to a highly significant extent particularly in terms of ovarian weight ($P<0.01$ and <0.001 respectively). This was also true of a dose of AMAN one fifth of the maximum tolerated, although at this dose no clinical symptoms or disturbance of normal growth were observed during the neonatal period. The protein synthesis inhibitors (PURO and FU) were less effective but still provided a partial protection against this dose of TP ($P<0.05$). Only ACT.D was completely without effect on the development of masculinisation in these animals. When these doses of inhibitors were given alone they had no significant effects on vaginal cycles, incidence of ovulation, ovarian morphology or ovarian weight.

The results of a similar experiment using 80 μg of TP are shown in Table 2. With this dose of androgen 90% sterility and 95% acyclicity were achieved and the ovarian weight was reduced to 40% that of controls. Again AMAN and OH-U produced effective protection against masculinisation ($P<0.001$ in terms of ovarian weight); evidence of ovulation in the form of corpora lutea was present in 100% of rats given the higher dose of AMAN. The lower dose of AMAN still afforded clear protection against 80 μg of TP ($P<0.01$); however, PURO failed to provide significant protection against this dose ($P>0.10$). Once again ACT.D was completely without a protective effect.

In a further experiment a dose of 200 μg of TP was used and in this case 100% sterility and acyclicity were achieved (Table 3). A high degree of protection was again obtained with OH-U, the effect being highly significant in terms of all the parameters tested ($P<0.01$ and $P<0.001$). Indeed the ovaries were almost equal in weight to the controls which received the inhibitor alone. AMAN was markedly less effective against this high dose of TP but 33% of the animals showed signs of ovulation ($P<0.05$) and their ovaries were significantly heavier than the TP controls ($P<0.01$) although much lighter than those of rats treated with the inhibitor alone ($P<0.001$).

It is clear from these results that substances that block the synthesis of DNA or of nucleoplasmic RNA can protect the newborn female rat from the permanent neural organising effect of neonatal androgen. Inhibition of protein synthesis is less effective in this respect, and inhibition of ribosomal RNA synthesis alone (as produced by the low doses of actinomycin D we have used[14]) is completely ineffective. The former may be because we were unable to achieve a complete block to protein synthesis in the brain. Three hours after the dose of puromycin, inhibition

of protein synthesis (by ^{35}S-methionine incorporation) was only 28% in the hypothalamus compared with 77% in the liver. Thus the lack of a protective effect of puromycin in these animals is still compatible with an obligatory role of protein synthesis in sexual differentiation of the brain.

The dependence of sexual differentiation on DNA synthesis, suggested by our results with hydroxyurea, has not been previously demonstrated. The failure of Barnea and Lindner[11] to achieve protection with hydroxyurea seems to conflict with this finding but, as these authors comment, very little is known of the time course of action of TP and it is quite possible that the effect may be more delayed than hitherto supposed. If this were the case our two large systemic doses of inhibitor given subcutaneously might well produce a longer lasting effect on the brain than their smaller doses given intracranially. This dependence is, however, entirely compatible with what is known of the process of hormone-induced differentiation in other tissues, notably the mammary gland[15]. It seemed important, therefore, to establish that some DNA synthesis was in fact continuing in the hypothalamus of the 4-d-old rat. We used ^{3}H-thymidine autoradiography to study this and have obtained evidence of DNA synthesis in both neuronal and glial cell nuclei throughout the brain, including the hypothalamus, at this age[16]. This is in accord with recent biochemical evidence obtained from whole brain fractionated into neuronal and glial nuclei[17]. Figure 1 illustrates a field in the anterior hypothalamic area but similar levels of labelling were observed in the medial preoptic area and the ventromedial/paraventricular region, the range being from 0.9 to 1.3% of cells labelled after 3 h exposure to ^{3}H-thymidine. The effect of TP on the frequency of thymidine labelling in this part of the brain is being investigated.

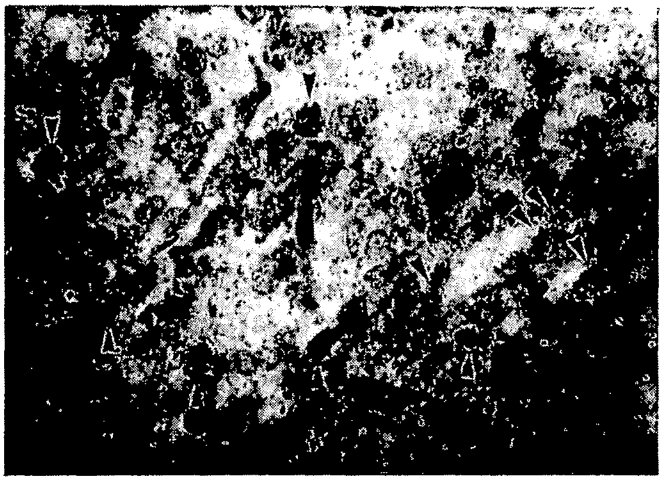

Fig. 1 Autoradiograph of parasagittal (8 μm) section from the anterior hypothalamic area (0.2 mm from the midline) of a 4-d-old female rat which received 50 μCi of ^{3}H-thymidine s.c. 3 h before death. Counter stained with nuclear fast red, exposed for 1 week at 4° C. Magnification ×390. Ten labelled nuclei are visible (arrows).

The protective action of α amanitin is equally striking since it is highly effective at a dose of one fifth of the maximum tolerated by the neonatal rat and one twentieth of that used by Tata *et al.*[13] to inhibit RNA synthesis *in vivo*. This suggests that the masculinisation process may be dependent on the synthesis of a few specific RNA molecules. It is possible that these may be histone or acidic nuclear-protein mRNA molecules the translation products of which would be necessary for the DNA synthesis that

might follow. Hydroxyurea is known to block the synthesis of these specific mRNAs selectively[18].

Although the precise mechanism of sexual differentiation remains obscure, it is apparent from these results that DNA, RNA and probably also protein synthesis is involved at an early stage; in this respect the process is closely analogous to hormone-induced differentiation in other tissues of the body, for example, in the mammary gland[15] or the erythropoietic system[19].

Dissociation of Stimulatory and Synthetic Phases in the Induction of Tyrosine Hydroxylase

RESERPINE treatment causes an increase in the activity of tyrosine hydroxylase (T-OH) in the superior cervical ganglion of the rat. A single systemic injection of the drug produces a rise in enzyme activity that reaches a maximum 48–72 h later[1]. No change in T-OH is seen if the preganglionic cholinergic tract is cut at the time of reserpine administration or if animals are pretreated with the ganglion blocking agents pempidine or chlorisondamine[2,3]. In the cat, direct electrical recording from the preganglionic cervical sympathetic trunk has revealed increased neuronal firing after reserpine administration[4]. These findings suggest that the rise in T-OH activity elicited by reserpine is mediated trans-synaptically through an increase in ganglionic transmission.

Little is known about the sequence of events that occurs between the injection of reserpine and the increase in T-OH activity. We have used a combination of *in vivo* administration of reserpine with subsequent *in vitro* maintenance of superior cervical ganglia to achieve a temporal dissociation of the trans-synaptic stimulation of the ganglia from the actual increase in T-OH activity. We have also used this system to assess the importance of continuing protein synthesis in the ganglion for the development of this increase in enzyme activity.

Adult male Wistar rats (250–350 g) were injected subcutaneously with 5 mg kg^{-1} reserpine (British Drug Houses, Poole) in 20% ascorbic acid or with the vehicle alone. Superior cervical ganglia were removed 24 or 72 h later and the ganglion sheaths removed. The ganglia were then either frozen at −20° C or placed in organ culture. The organ culture system involved placing ganglia on Millipore filters supported on metal grids in Falcon organ culture dishes (Becton, Dickinson and Co., Wembley, Middlesex). Eagle's minimum essential medium was supplemented with glucose (to 600 mg%), neonatal calf serum (10% v/v) and penicillin and streptomycin (100 IU ml^{-1}). The dishes were incubated at 37° C in an incubator perfused with humidified 95% O_2 and 5% CO_2 for 48 h. After incubation, ganglia were washed thoroughly in basic salt solution and stored at −20° C until assayed. Individual ganglia were homogenised in 20 or 60 µl of 5 mM Tris buffer, *p*H 7.4, containing 0.1% Triton X-100. Tyrosine hydroxylase activity was assayed in 10 µl aliquots using L-tyrosine (2,3,-^{3}H-side chain) as substrate at a concentration of 8 µM (ref. 5). Protein content was determined using the method of Lowry[6].

Table 1 Tyrosine Hydroxylase Activity in Rat Superior Cervical Ganglia Following Reserpine Treatment

	T-OH activity as % *in vivo* controls
In vivo controls	100±11
Reserpine 24 h	102± 6
Reserpine 72 h	186±10
Culture controls	86± 4
Reserpine culture	158± 9 (185±10% of culture control)

The tyrosine hydroxylase activity in the five experimental groups is expressed as a percentage of the *in vivo* controls. Means and s.e.m. are based on groups of thirty ganglia (pooled results from five experiments). The tyrosine hydroxylase activity in the *in vivo* controls was 350 pmol dopa per h per mg protein. 'Reserpine 24 h' and 'reserpine 72 h' refer to values obtained from ganglia removed from animals 24 h and 72 h after administration of reserpine (5 mg kg^{-1}, subcutaneously). 'Culture' results were from ganglia maintained in organ culture for 48 h; 'Reserpine culture' results from ganglia explanted 24 h after administration of reserpine.

Five experimental groups were studied: '*in vivo* controls' (ganglia from rats injected with vehicle alone 24 or 72 h previously), 'reserpine 24 h' (ganglia from rats injected 24 h previously with reserpine), 'reserpine 72 h' (ganglia from rats injected 72 h previously with reserpine), 'culture controls' (ganglia excised from rats injected with vehicle alone 24 h previously and subsequently maintained for 48 h in organ culture), 'reserpine culture' (ganglia from rats injected 24 h previously with reserpine and subsequently maintained for 48 h in organ culture). The *in vivo* control level of T-OH activity was 350 pmol dopa per h per mg protein. No change in T-OH activity was observed in the reserpine 24 h group when compared with the *in vivo* controls. The reserpine 72 h ganglia, however, showed an 86% increase (Table 1). Over the 48 h culture period, the T-OH activity in the culture control ganglia fell on average to 86% of the *in vivo* controls. On the other hand, the reserpine culture group showed a 58% rise in T-OH activity relative to *in vivo* control and an 85% rise relative to 'culture control'. Thus ganglia removed from the animal before any increase in T-OH activity had developed showed an increase in the enzyme in culture comparable with that which would have been achieved *in vivo*. These findings

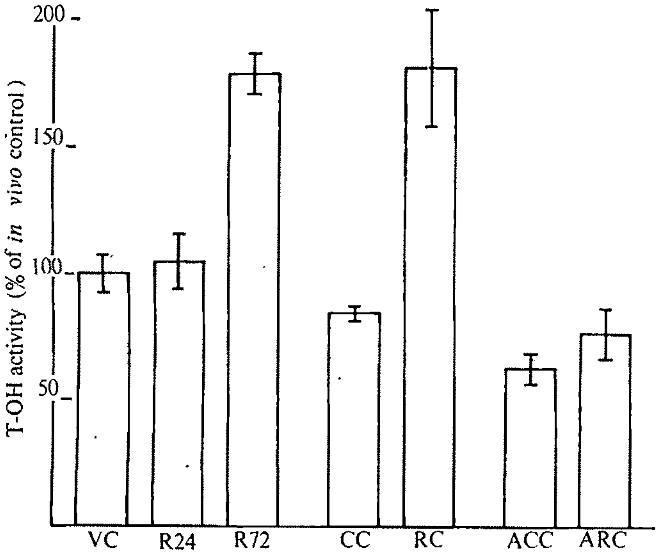

Fig. 1 Effect of anisomycin on the increase in tyrosine hydroxylase activity following reserpine treatment. The means ± s.e.m. are expressed as percentages of *in vivo* control values. Six ganglia were assayed in each group. The groups were: VC = *in vivo* controls, R24 = reserpine 24 h, R72 = reserpine 72 h, CC = culture control, RC = reserpine culture, ACC = anisomycin (2 μg ml^{-1}) culture control, ARC = anisomycin (2 μg ml^{-1}) reserpine culture. Mean tyrosine hydroxylase activity of *in vivo* control group was 350 pmol dopa h^{-1} per mg protein. For details see Table 1 and text.

suggest that any stimulation of the ganglion in the intact animal beyond that achieved within 24 h of a single injection of reserpine is unimportant to the expression of increased T-OH activity.

To investigate the role of protein synthesis in the development of increased T-OH activity one group of reserpine culture ganglia was maintained for 48 h in the presence of anisomycin, a specific blocker of peptide bond formation[7], at a concentration of 2 μg ml^{-1} in the culture medium. The enzyme activity was compared with that of a similar group of reserpine culture ganglia maintained for 48 h in normal medium. The T-OH rise normally seen after reserpine was completely abolished in the anisomycin-treated group (Fig. 1). This finding that inhibition of protein synthesis in the isolated ganglion abolished the reserpine-stimulated rise in T-OH activity confirms earlier interpretations of the effects of cycloheximide administered to the whole animal[8]. Our results clearly demonstrate that an important site of this effect of protein synthesis inhibitors is the ganglion itself.

By removing the ganglion from the animal and maintaining it in culture we have been able to show that after a period of stimulation the adrenergic cell bodies can produce an increase in T-OH activity when isolated from the neural and humoral changes produced *in vivo* by reserpine. Furthermore, this increase in enzyme activity is dependent on protein synthesis.

A recent study using actinomycin D suggests that the transcriptional phase of the rise in T-OH activity of rat stellate ganglia evoked by a 2 h exposure to stress is complete 24 h later[9]. Other workers have found that 12 h after insulin treatment actinomycin D can no longer prevent the insulin-induced rise in adrenal T-OH activity[10]. The time course of events following reserpine treatment has still to be elucidated.

The system we have described should provide a useful means of investigating this and other questions concerning the cellular mechanisms by which neurones respond to trans-synaptic stimulation.

Preparation of Frozen Hydrated Tissue Sections for X-ray Microanalysis in the Scannning Electron Microscope

THE technique of X-ray microanalysis, using a finely focused beam of electrons to excite characteristic X rays from the elements present in a specimen, is proving to be a powerful tool in the investigation of biological systems. Its main limitation has been that, in common with all electron-optical methods, the specimen must first be stabilised by removal or immobilisation of cell and interstitial water. Conventional chemical fixation techniques give excellent structural preservation, but also cause gross permeability changes in cell membranes and, together with subsequent dehydration, lead to substantial loss or redistribution of free electrolytes. Freeze drying suffers from a similar limitation, in that removal of water must inevitably redistribute electrolytes which move to the remaining structures such as cellular membranes.

To study the distribution of water-soluble ions in biological systems, we have therefore developed a technique for immobilisation of water and solutes by rapid freezing, followed by sectioning and examination of the tissue while still in the frozen, hydrated state, that is with cellular and interstitial water retained as ice at a low temperature. A similar approach is also being adopted by Gehring *et al.*[1] and by Hutchinson (private communication).

Full details of the preparative procedure are given elsewhere in papers on technique[2–5]: the principal purpose of this communication is to describe our first successful results. The specimens were salivary glands isolated from 2 to 3-d-old larvae of the blowfly (*Calliphora*). These were mounted in either insect blood or a balanced medium[6] on an aluminium chuck and quench frozen in liquid fluorocarbon at −150° C (ref. 3). The chuck was transferred to a Slee retracting microtome in a large cryostat chamber at −85° C, and sections 1 to 2 μm thick were cut using a steel knife. Sections were picked up on aluminised nylon support films[5], stretched over aluminium collars designed to fit into a copper specimen holder for examination and microanalysis. The collars with

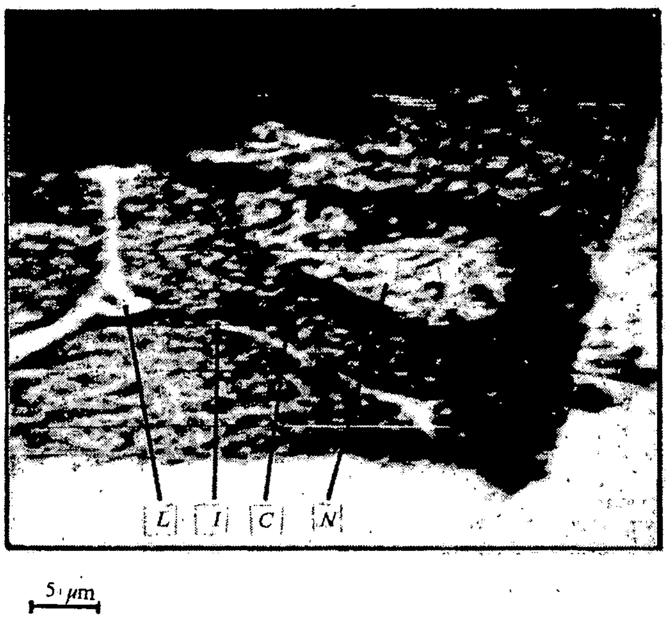

Fig. 1 Scanning transmission electron micrograph showing a frozen, hydrated transverse section of a blowfly larval salivary gland. *C*, Cytoplasm; *N*, nucleus; *L*, lumen; *I*, intercellular cleft.

sections attached were immediately immersed in liquid nitrogen, where they could be stored before fitting into the specimen-holder. Contamination of microtome and sections by surface ice was prevented by careful exclusion of atmospheric air during sectioning and transfer: the cryostat chamber was divided by a vertical polyethylene curtain separating the manipulation area from the microtome, and all manipulations were carried out either in the cryostat or under liquid nitrogen.

For critical work using diffracting spectrometers and high probe currents, it would be desirable to coat the mounted specimens, still maintained at a low temperature, with a further layer of evaporated metal to improve their stability and conductivity. In the experiments described here, where an energy-selective spectrometer and moderate beam currents were used, this complication was found not to be necessary and was omitted. The mounted sections, under liquid nitrogen, were enclosed in a protective metal cap[5] and transferred directly to the pre-cooled stage of a Stereoscan S4 scanning electron microscope (Cambridge Scientific Instruments Ltd).

The cold-stage consists of a standard Cambridge Instruments Series 200 microanalysis stage with hot-cold module, which we have modified to allow the examination of thin specimens in the transmission mode[3]. The detector for transmitted electrons is a silicon solar-cell (Centralab, California) approximately 2 mm in diameter, mounted about 40 mm below the specimen and coupled through a pre-amplifier to the video system of the Stereoscan. Our modifications have also increased the working distance from the specimen to the final lens of the microscope to about 18 mm. This allows us to insert the 'nose' of a lithium-drifted silicon X-ray detector (active area 25 mm^2; Quartz et Silice, Paris) close to the horizontally mounted specimen.

Figure 1 shows the scanning transmission electron image of a transverse section of a salivary gland, taken with an operating potential of 30 kV. Resolution at this potential is severely limited by scattering of electrons in the specimen, which is relatively thick compared with those normally used for transmission electron miscroscopy. Contrast is good, however, and the major cellular features are clearly identifiable.

X-ray microanalysis was carried out by advancing the detector as close as possible to the specimen (distance 10 to 15 mm) and allowing the electron beam to scan an area of specimen 5 μm square. Figure 2 shows X-ray spectra from areas in the nucleus, cytoplasm and lumen of the gland, each obtained with a 30 kV, 4 nA probe over an irradiation period of 100 s. The stage temperature was −160° C. The spectra show clearly the presence of a large concentration of potassium in the cell, but not in the lumen. Phosphorus and sulphur are also present in the cell; signals from copper, iron and silicon are background resulting from scattered electrons, and that from aluminium is generated mainly in the supporting film. Although these spectra do not by themselves permit accurate quantitative microanalysis, they are sufficient to show that ions are retained in the specimen during preparation. By using stable inorganic standards and the higher X-ray resolution obtainable with diffracting spectrometers, fully quantitative measurements will be possible.

Stability of the specimen under the beam was investigated by using the X-ray continuum intensity as a measure of the total mass in the irradiated portion of the specimen[7]. In Fig. 3, *A* shows local mass as a function of time in conditions similar to those used for microanalysis. The curve is similar to those obtained by Hall and Gupta[8] from cooled, freeze-dried tissue sections, showing only a very slow loss of material due to chemical and thermal damage by the high-energy electron beam. The early loss of mass which is normally found with room-temperature specimens was found in the present experiments only after the specimen had been warmed (Fig. 3*B*). It is thus very unlikely that any substantial loss or redistribution of inorganic ions could take place as a result of irradiation.

Apart from a brief period at about −80° C during sectioning, the temperature of the specimen during preparation and transfer never rose above −120° C, and it was always protected from exposure to the air. It is therefore most unlikely that any melting or drying would occur. Direct evidence that the specimen as examined was indeed hydrated

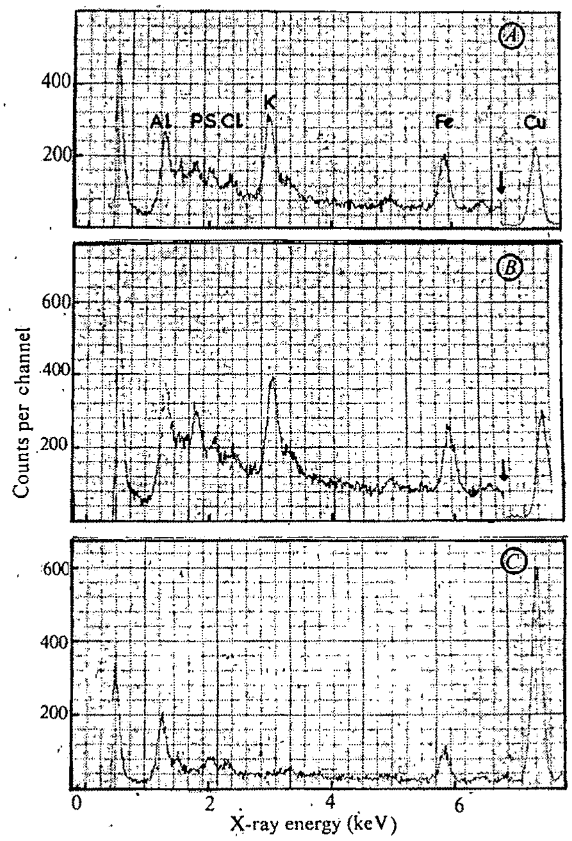

Fig. 2 X-ray spectra from the specimen of Fig. 1. *A*, Nucleus; *B*, cytoplasm; *C*, lumen. In *A* and *B* the vertical scale was reduced by a factor of 5 at the arrowed point, to keep the copper peak on scale.

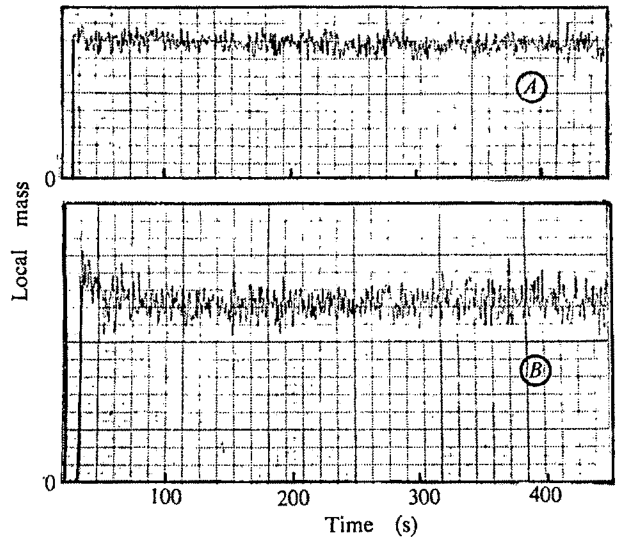

Fig. 3 Local mass (arbitrary units) against time during irradiation of the specimen. *A*, At −160° C; *B*, at room temperature, after sublimation of ice from the specimen.

was obtained by allowing the stage temperature to rise slowly, while continuing to watch the scanning transmission and secondary-electron 'reflection' images. At about −75° C, a transient rise in vacuum pressure indicated the sublimation of ice from stage and specimen, and was accompanied by an increase in contrast of the transmission image. The secondary-electron image, which had previously been almost featureless, now showed recognisable outlines of the cells (this is consistent with the results of Gehring *et al.*[1], who found it necessary to etch the surface of a frozen bulk specimen, in order to obtain a useful secondary-electron image).

We believe that Fig. 1 is the first scanning transmission electron image to be obtained from a frozen, hydrated tissue section, with firm evidence that the specimen did not suffer dehydration during preparation, transfer or examination. Although these results are of a preliminary nature, and do not in themselves significantly advance our knowledge of cells and tissues, we believe that they demonstrate the feasibility of a technique which is capable of providing answers to numerous biological problems. From the present results to the analysis of ion distributions as they exist in living tissues, on a scale of 1 μm or less, is a step involving no more than the use of more specialised instrumentation already commercially available.

Number of Ouabain-binding Sites in Fibroblasts from Normal Subjects and Patients with Cystic Fibrosis

One of the characteristics of cystic fibrosis (CF), an autosomal recessive disease, is a defect in the net sodium transport in the eccrine glands resulting in an increased concentration of sodium in the sweat[1]. This defect has yet to be characterised as an extrinsic and/or intrinsic phenomenon. Mangos and McSherry[2] demonstrated an unidentified factor in the sweat from CF patients which inhibited sodium reabsorption in the rat parotid duct after retrograde perfusion. The relationship of the sweat factor to factors observed in saliva[3] and sera[4,5] of CF patients has yet to be elucidated.

Although there is no direct evidence for an intrinsic defect within the gland, studies of erythrocytes indicate that a defect could exist. Balfe *et al.*[6] reported abnormal sodium transport in erythrocytes from CF patients; Lapey and Gardner[7] demonstrated a decrease in the pump II component of sodium efflux in male CF patients; and Horton *et al.*[8] reported a decrease in calcium-activated ATPase in CF erythrocytes. Fitzpatrick *et al.*[9] observed an altered electrophoretic pattern of CF erythrocyte membranes, which they interpreted as an altered calcium-binding component in the membrane. However, Hadden *et al.*[10] could not demonstrate significant differences in the sodium-potassium ion exchange and in the calcium efflux pump of CF and normal erythrocytes when comparisons were matched for age and sex.

Recently, binding of ^{3}H-ouabain to the cell membrane has been used to determine the number of ouabain-binding sites per cell in red blood cells[11–13], in cultured Girardi heart cells[14], and in HeLa cells[11,15,16]. These studies demonstrated a direct correlation between the number of ouabain-binding sites per cell (at low ouabain concentrations) and the Na^{+}–K^{+} ATPase activity.

As Hadden *et al.*[10] have said, the differences observed between CF and normal erythrocytes are difficult to interpret because the CF cells may be affected by the anoxia, infection, malabsorption, liver disease and vitamin or antibiotic therapy seen in CF patients. Recently, Fletcher and Lin[18] found no differences in the Na^{+}–K^{+} ATPase activity, measured in a heavy particulate fraction from fibroblasts of normal subjects and CF patients after cell homogenisation. Because of possible complications in the erythrocytes from CF patients, and since the activity observed in a cell homogenate may not express the situation in the intact cell, we have looked for differences in the binding of ^{3}H-ouabain in cultured normal and CF human diploid fibroblasts.

Human fibroblast cell strains were established from skin biopsy explants. The fibroblasts, after outgrowth, were frozen and stored in liquid nitrogen. The three normal and three CF fibroblast cell strains used had undergone less than ten subcultures since the establishment of the cell strain from the biopsy. The fibroblasts were cultured in F-12 (Gibco) containing 15% foetal calf serum (Gibco) and 100 U ml^{-1} of penicillin and 100 μg ml^{-1} streptomycin.

The number of binding sites for CF and normal human diploid fibroblasts was determined on cells in log phase (Fig. 1). The initial determination was made 24 h after inoculation of the cultures and additional determinations were carried out on days 2 and 4. As Figure 2 shows, we observed no appreciable differences in the number of ouabain-binding sites between normal and CF cell strains. The mean number of sites per cell for the normal fibroblasts was $7.0 \times 10^6 \pm 2.3$ s.d. and for the CF fibroblasts $8.3 \times 10^6 \pm 1.5$ s.d.

Boardman *et al.*[16] found that HeLa cells, after exposure to sublethal levels of ouabain for 24 h, had an increased number of ouabain-binding sites per cell and a concomitant increase in their Na^+–K^+ ATPase activity. Thus the cells compensated for the decreased Na^+–K^+ ATPase activity caused by ouabain inhibition of the enzyme. Since there was no apparent change in the number of binding sites during logarithmic growth of the CF cell strains (Fig. 2), it seems that the ciliary dyskinetic factor which accumulates in the media of CF fibroblasts[17] does not interfere with their Na^+–K^+ ATPase activity. Furthermore, the constancy in the number of ouabain-binding sites in CF fibroblasts indicates that the factor does not appreciably affect the permeability of the plasma membrane; that is, an increased number of binding sites would be expected[16] to maintain the normal intracellular ionic environment if the permeability of the membrane had increased.

Our observations also agree with the studies of Fletcher and Lin[18], who observed no differences in the membrane ATPase activity and its response to inhibition by ouabain and ethacrynic acid in CF and normal fibroblasts.

We were also unable to observe any differences in the kinetics of ouabain-binding between normal and CF fibroblasts in K^+-free phosphate-buffered saline solution, and the results were essentially the same as those seen in HeLa cells[15,16]; that is, saturation was achieved within 30 min at 37° C (2.0×10^{-7} mol l^{-1} ouabain) and remained constant for more than 1 h.

The studies on the Na^+–K^+ ATPase in CF fibroblasts, measured in a heavy particulate fraction from a cell homogenate, have indicated no observable differences in the specific activity of the Na^+–K^+ ATPase nor any alteration in the inhibitory pattern of the Na^+–K^+ ATPase *per se*[18]. Using intact cells, we observed no alterations in the kinetics of binding of ouabain nor any alteration in the total number of binding sites. These data indicate that the Na^+–K^+ ATPase functions normally in the CF fibroblast.

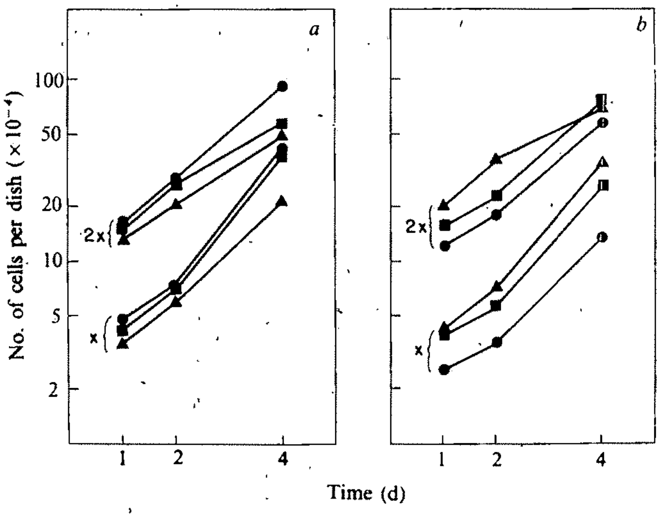

Fig. 1 The cell strains were grown to confluency and trypsinised. The resultant suspensions of cells were inoculated into P-60 Falcon tissue culture dishes at an approximate cell concentration of 4 (X) and 8 (2X) × 10^4 cells per dish. The cells were cultured in F-12 (Gibco) containing 15% foetal calf serum. At day 1, 2, and 4, 3 P-60 Falcon plastic dishes for each cell strain at each cell density were washed with saline, trypsinised and the total cell number per dish was determined. Results shown are the mean of the three determinations. *a*, Normal fibroblast: strains were (▲), No. 17; (■), No. 18; (●), No. 31. *b*, CF fibroblast: (▲), No. 2; (■) No. 4; (●), No. 24.

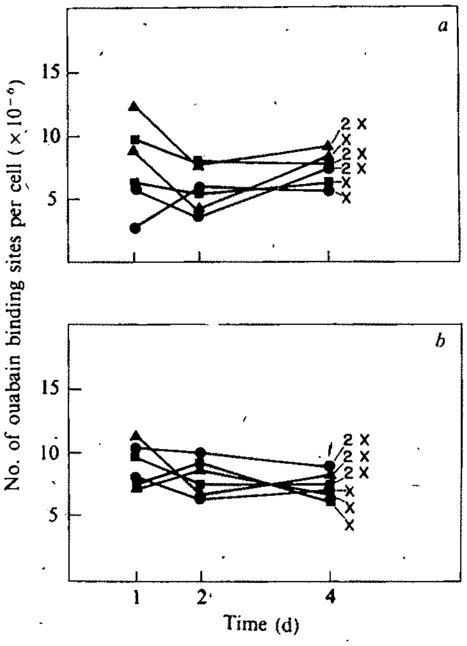

Fig. 2 The cell culture media were removed and the cells were washed with a potassium-free phosphate-buffered saline, *p*H 7.4, 37° C, which contained 0.01% glucose (PBS-g). The ^{3}H-ouabain (New England Nuclear Corp.) was added in a PBS-g solution (37° C), and the cells were incubated for 30 min. The ^{3}H-ouabain solution was removed, and the cells were washed four times with excess quantities of PBS-g at 0° C. The final wash was removed, the cells were trypsinised, and the entire contents of the culture dish were transferred to counting vials for liquid scintillation counting. The ouabain concentration used was 2.08×10^{-7} mol l^{-1}, and the specific activity was 2.3×10^7 mol per d.p.m. Each point corresponds to the mean of three determinations. X and 2X correspond to the inoculum cell concentration. The cell number per dish at the time of each determination is seen in Fig. 1. *a*, Normal fibroblast: strains were (▲), No. 17; (■), No. 18; (●), No. 31. *b*, CF fibroblast: (▲), No. 2; (■), No. 4; (●), No. 24.

Resistance to Marek's Disease in Immunologically Deficient Chickens

A CELL-ASSOCIATED herpesvirus has been shown to induce Marek's disease (MD), a naturally occurring malignant neoplasm of chickens. The mechanism of tumorigenesis or the factors that mediate natural or acquired resistance to MD are not well understood. Information on these aspects is needed for a better understanding of the basic mechanisms of this and possibly other herpesvirus-induced neoplasms.

Inherited resistance of chickens to MD has been known for many years[1], and several inbred lines selected for natural resistance are available. We observed that chickens of one such line, designated line 6, when exposed to MD virus (MDV), developed persistent viraemia and antibody but no clinical disease[2]. The mechanism of resistance is unknown, but in confirmation of Calnek's observations on another genetically resistant line[3], we found that line 6 chickens produced a better virus neutralising (VN) antibody response than simultaneously inoculated genetically susceptible chickens. Thus, it was postulated that genetic resistance to this disease has an immunological basis and may depend on the ability of chickens to produce VN antibody. In testing this postulate I reasoned that since antibody synthesis is a function of cells derived from the bursa of Fabricius[4], response to MDV inoculation of bursectomised genetically resistant chickens should provide proof of the involvement of humoral antibody in this type of resistance.

Two experiments were conducted. The White Leghorn chickens used had maternal MD antibody at hatching. Chickens of line 6 known to be resistant to clinical MD[2,5] were either surgically bursectomised on the seventeenth day of embryonic life or sham operated as described by Van Alten *et al.*[6]. Surgical bursectomy at or before this stage eliminates or severely impairs the ability of chickens to synthesise both IgM and IgG[7]. One week after hatching, bursectomised, sham operated and untreated chickens of line 6 and line 7 hatchmates (highly susceptible line) were either inoculated with the JM 19 clone[8] of MDV (1.8×10^5 and 1.0×10^5 PFU per chicken in experiments 1 and 2 respectively), or left as uninoculated controls. In both experiments 33–44% of hatched chickens from bursectomised and sham operated groups died of herniated gut before virus inoculation. Each group was maintained in a separate Horsfall–Bauer isolator under negative pressure and was given regular feed and medicated water (Floxaid, 2 ounces per 50 gallons of drinking water, Merck). At 4 and 6 weeks old, each bursectomised and sham operated chicken was inoculated intramuscularly with 10^9 sheep erythrocytes suspended in 0.5 ml of phosphate-buffered saline. The inoculum was deposited at either a single site or three different sites in the same bird.

In both experiments, 8 weeks after inoculation, all surviving chickens were bled by cardiac puncture and then killed. Certain groups were tested for levels of viraemia by inoculating white blood cells from individual chickens onto secondary cultures of duck embryo fibroblasts[9] and counting foci of cytopathic effects 10–14 d later. Plasma or serum samples were tested by some or all of the following tests: agar gel precipitin (AGP)[10], immunofluorescent (IF)[11] and VN tests for anti-MDV antibody[2]; haemagglutination (HA) test for anti-sheep erythrocyte agglutinins[12]; radial diffusion test[13–15] for values of IgM and IgG (conducted by Dr M. D. Cooper). All chickens were examined grossly and the following sections were taken for histological examination: both vagi, right and left sciatic, and right and left brachial plexuses, gonads, spleen and bursa. If bursal remnants could not be detected grossly, a small area at the usual location of the bursa was sectioned. All sections were stained with haematoxylin and eosin and additional sections of spleen were stained with methyl green-pyronin also[16].

Since the design and results of both experiments were similar, data were pooled and are given in Tables 1 and 2. Of sixteen survivors in the bursectomised group, eleven had no detectable bursal remnant. These eleven were all deficient in bursa functions, that is, they produced no anti-sheep erythrocyte agglutinins, they had no detectable germinal centres in spleen and their sera lacked detectable levels of IgM and IgG (Table 1). The five chickens with bursal remnants and all sham operated chickens had well developed bursa-dependent functions (Table 1). The response of bursectomised, sham operated and untreated line 6 chickens to MDV is given in Table 2. Only the chickens that lacked gross and microscopic evidence of bursa and bursa-dependent functions are included in the bursectomised group. The incidence of MD in genetically susceptible line 7 chickens was high (approximately 90%), indicating that MDV inoculum was highly pathogenic. However, clinical MD did not develop in bursectomised, sham operated and untreated chickens of genetically resistant line 6. Bursectomised chickens lacked AGP, IF and VN antibody against MDV in contrast to the high incidence of antibody detectable by all three tests in sham operated and untreated groups. Four of eleven bursa-deficient chickens had viraemia, evidence that chickens in this group were infected with MDV. In one experiment, five of thirteen uninoculated control chickens of line 6 had AGP antibody indicating inadvertent exposure to MDV. However, infection in this control group apparently did not affect the outcome of this study because in the second experiment where control chickens remained free of MD the results were similar.

In this study, although a limited number of bursectomised chickens were available, the results were considered valid because a complete morphological and functional depletion of bursa was achieved without endangering the functions of other tissues or systems. Also, since line 6 chickens are highly resistant to MD, any variation in their response would have been detectable even among the small numbers used.

These experiments demonstrated that bursectomised chickens of line 6, although devoid of immunoglobulins, maintained their resistance to MD. Unpublished studies of Payne and Rennie (quoted by Payne[17]) reportedly produced similar results. Although these studies strongly suggest that the ability to synthesise humoral antibody was not a critical factor

Table 1 Bursa-dependent Functions in Bursectomised and Sham Operated Line 6 Chickens

Embryonic treatment	Bursal remnant*	No. of chickens	Germinal centres per spleen section†		HA titre ($\log_2$)‡		mg% IgM in serum		mg % IgG in serum	
			Mean	Range	Mean	Range	Mean	Range	Mean	Range
Bursectomy	Absent	11	0.0	—	0.0	—	0.0	—	0.0	—
Bursectomy	Present	5	6.15	2–11	6.8	3–≥9	29.4	13.5–44.7	48.9	26.0–95
Sham operated	Present	18	15.45	3–36	7.2	5–≥9	27.6	13.5–55.1	109.3	0.0–201.0

Data were pooled from two experiments.
* Detectable by gross and (or) microscopic examination.
† Spleen was sectioned approximately through the middle and all germinal centres present in the entire cross section were counted.
‡ Sheep erythrocyte agglutinins.

Table 2 Response of Bursectomised, Sham Operated and Untreated Chickens of Line 6 to Marek's Disease Virus (MDV) Inoculation

No. of chickens	Embryonal treatment	Inoculum	Viraemia		MD-Antibody†				MD		
			+/ tested	Mean* titre	AGP +/ tested	VN +/ tested	IF +/ tested	Mean titre	No. died	No. with lesions‡ at termination	Total MD
11	Bursectomised	MDV§	4/11	2.6	0/11	0/11	0/11	0	0	0	0/11
18	Sham operated	MDV	2/18	0.25	12/18	18/18	18/18	≥142	0	0	0/18
29	None	MDV	NT	NT	28/28	NT	28/28	≥134	0	0	0/28
28	None	None	NT	NT	5/28¶	NT	NT	NT	0	0	0/28

Data are pooled from two experiments. NT, not tested.

* PFU per 10^7 white blood cells.

† AGP test was done on undiluted sera. For VN test, all samples were diluted 1 : 20. The IF antibody titre corresponds to the reciprocal of highest serum dilution giving a positive reaction (1 : 160 was the highest dilution tested).

‡ Gross or microscopic.

§ The MDV inoculum induced MD in approximately 90% of simultaneously inoculated line 7 chickens.

¶ Presence of AGP antibody indicates inadvertent exposure to MDV of this group in one experiment.

in resistance to MD, the following points must be considered before definite conclusions are reached.

(1) It can be postulated that bursa-derived (B) cells act as target cells for lymphoma formation by MDV and that embryonic bursectomy eliminated all available B cells from the host. Indeed, in lymphoid leukosis, another haematopoietic neoplasm of chickens, neoplastic transformation originates in the cells of the bursa of Fabricius and bursectomy during early stages of infection prevents clinical disease[18–20]. Thus, by this reasoning, lack of MD in bursectomised chickens was due basically to the lack of target cells. Although conclusive proof is lacking, available data suggest that the target cell in MD is not a B cell. The most direct evidence comes from the observation that MD lymphomas can be induced in susceptible, bursectomised, X-irradiated, agammaglobulinaemic chickens[21]. However, in this study, bursectomy and X-irradiation were performed at hatching, and since bursa-derived cells peripheralise during embryonic stages, it is possible but unlikely[22] that some B cells were available at the time of virus inoculation. Conclusions of Foster and Moll that bursectomy decreased MD[23] were not confirmed by others who found bursectomy either to have no effect[21,24] or to enhance the severity of MD in susceptible chickens[25,26]. Also, Hudson and Payne[27] and Rouse *et al.*[28] found that in MD lymphoma, most lymphoid cells (80% or more) were of thymic origin.

(2) Line 6 chickens used in this study had maternal antibody against MDV at hatching and bursectomy presumably did not influence the protective effect this antibody may have had on their response. Although this argument cannot be settled until after a similar study of line 6 chickens without maternal antibody, it seems unlikely that maternal antibody alone was responsible for the resistance in these chickens. Studies where the protective effect of maternal antibody was quantitated[29] showed that susceptible chickens with maternal antibody could neutralise approximately 1 $\log_{10}$ of cell-associated virus. Since in my study, line 6 chickens were challenged with 10^5 or more PFU of pathogenic MDV, and a dose of 1 PFU or less can induce neoplastic response in the susceptible chicken[5], it seems unlikely that maternal antibody seriously affected the outcome of this study. Nonetheless, in view of Calnek's observation[30] that maternal antibody was important in the expression of early resistance of N line chickens, the role of maternal antibody in MD needs further clarification.

The mechanism of resistance to MD is not clear. Suggestions include (*a*) selective ability of resistant chickens to produce VN antibodies[2,3]; (*b*) cell-mediated immunity[17]; (*c*) increased production in resistant chickens of non-specific inhibitors such as interferon[31]. Although these possibilities may not be mutually exclusive, the study reported here clearly demonstrates that ability to produce antibody is not required in the expression of resistance to MD.

I thank Dr M. D. Cooper, University of Alabama, for demonstrating embryonal bursectomy and for conducting tests for IgG and IgM. I also thank Drs H. G. Purchase and R. L. Witter for advice and assistance. Chickens were made available through Mr H. A. Stone. Mrs Evelyn Young and Mrs Karen Juntikka provided technical assistance.

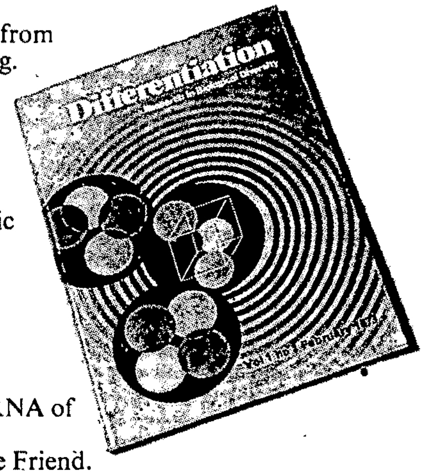
Biologic l diff r nti tion -a new journal.



Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation.

The first three issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.
Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.
Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Biesele, J. S. Morgante and M. C. Garrido.
The principle of sequential dependence in cellular differentiation. P. A. Riley.

The next issues of Differentiation will contain:
Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.
Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.
Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.
The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.
DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.
Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.

The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

PROGRESS IN BIOPHYSICS & MOLECULAR BIOLOGY

Editors
J A V Butler
Emeritus Professor of Physical Chemistry, University of London
D Noble
Balliol College, Oxford

In this series are published articles of substantial length, most of which take a broad perspective view of the subject rather than going into detailed discussion of specialized points. As the various aspects of biophysics are of interest to diverse groups of research workers, some of whom may not be as familiar with biophysical principles as they would like, contributors are encouraged to explain and illustrate their topics in a comprehensive and readable style. PROGRESS IN BIOPHYSICS AND MOLECULAR BIOLOGY is read by final-year undergraduate and postgraduate students and non-experts, as well as by research workers in biophysics and molecular biology.
The series is published in hard cover with a new volume appearing about every six months. The review articles in PROGRESS IN BIOPHYSICS AND MOLECULAR BIOLOGY are of interest to biophysicists, molecular biologists, physiologists, pharmacologists, bio-engineers and zoologists; those people who are concerned with the practical applications of biophysics in medicine and biology will find much relevant reading within the volumes of this series.

Volume 27

399 pages £10.00

book reviews

Nutrition reviewed

World Review of Nutrition and Dietetics. Edited by Geoffrey H. Bourne. Vol. 17 pp. xii+318; vol. 18 pp. 336. (Karger: Basel, London and New York, September and October 1973.) Vol. 17: Sfr. 144; £20.90; $57.75; vol. 18: Sfr. 165; £23.95; $59.15.

THE two latest volumes of this ambitiously named series contain three quite different types of contributions; one group is composed of technical reports of particular aspects of biochemical research; the second, consisting of two papers, contains accounts of the changes in food supply and their consequent effect on nutrition in different communities; while the third, again made up of two contrasting pieces of writing, deals with the very different philosophical outlooks with which workers of different origins have come, after a generation of hard experience, to view the practice of applying nutrition and dietetics to the problems of diverse communities. In spite of the wealth of scholarship deployed in the 654 pages of the two books, it would be a naive purchaser who, after paying the combined price of £44.85, considered that he had received his money's worth.

Some of the research reviews are excellent. E. B. Olsen and H. F. De Luca contribute an admirable paper to volume 17 on the recent advances in understanding of the metabolism and mechanism of action of vitamin D. That by I. Szelenyi in the same volume on magnesium and its significance to cardiovascular and gastro-intestinal disorders is also stimulating, as a review article should be. For anyone who wants to know all about the use of molasses for feeding cattle or about the use of citrus fruits for feeding people (apparently more citrus fruit is eaten than any other kind), T. R. Preston has an exhaustive paper in volume 17 and J. Kefford an equally comprehensive one in volume 18. C. G. King contributes a good review covering the biological synthesis of ascorbic acid which possesses the added advantage of being succinct; the paper by J. T. Snook on protein digestion is equally good.

The two articles, one by S. C. Hsu describing what has happened to nutrition in Taiwan between 1945 and 1970, in volume 17, and the other by E. Ferber reviewing conditions in Yugoslavia between 1953 and 1963, in volume 18, take us into a different area of nutrition and dietetics. The minutiae of the biochemistry of vitamins, of magnesium and water-borne goitrogens, about which E. Gaitan has an article in volume 17, are some of the essential bricks from which our knowledge of nutrition is built up. What use can be made of the edifice of scholarship is demonstrated in the narrative of communities of real people. It is easy to see that the work in Taiwan was influenced by American thinking. The tables of figures are all there, the dietary surveys, anthropometric data and plans to regulate the labelling of food and provide nutrition education for the public. In brief, the story is one of rapidly increasing prosperity, increased consumption of food in general and fish, pork and chicken in particular, bigger children, the disappearance of nutritional deficiency diseases and—you've guessed it—a rise in the mortality from vascular disease and an increased incidence of gout. Here, indeed, is the full gamut of nutritional science.

The narrative in Yugoslavia is the same but with a difference. Here too a rural population took to the industrial life. The people left the villages to work in the towns where imported food was provided. As they became richer they too ate better while those left behind had a poorer diet. But while this difference persisted and, as Ferber points out, despite the intrusion of combines, cars and television, regional dietary habits and customs remained. Nevertheless, in the country as a whole the consumption of meat, fruit and vegetables rose while the proportion of cereals fell. At the same time pellagra and rickets dwindled away. Ferber surely has the last word when he writes "all efforts of the health policy group would be futile without the advancement of the economic basis of the population".

J. Trémolières, in the third type of article, writes in volume 18, as he has done elsewhere before, to imply that food has a symbolic significance apart from its chemistry and that people are different from the nutritional statistics in which we sometimes purport to describe them. "Reference Man" must always be based on the particular community to which he is intended to be applied.

Finally, there are thirty-five pages in volume 17 by J. E. Gordon and N. S. Scrimshaw—surely written on an off day. This too is a philosophical exposition of their views on how to decide whether action planned to improve a community's nutrition has done any good or not. "Essential components are to establish the goals of professional achievement for nutritional and allied variables, the means for their measurement, a standardisation of performance in their execution and quality control of the assembled data", write the authors or, alternatively, "the approach to evaluation of a nutrition action programme is ecologic, wherein epidemiologic method provides the means to measure effect".

If Dr Geoffrey Bourne, the indefatigable editor of the series, could persuade some of the contributors to knock off a word here and there, he might be able to get the publishers to reduce the price. MAGNUS PYKE

Ways with cells

New Techniques in Biophysics and Cell Biology. Edited by R. H. Pain and B. J. Smith. Vol. 1 pp. 249. (Wiley-Interscience: London and New York, September 1973.) £5.73.

THIS little book clearly emphasises how present-day biology depends on technical innovation. Like all multi-author works, it is heterogeneous in style and approach. Some of the eight chapters describe in detail the theory behind each technique but are thin on useful applications, whereas others list the various problems successfully tackled but with a minimum of theoretical background.

New Techniques begins with an account by J. Edwards of intercellular adhesion in which the Coulter counter is fully exploited to study aggregation of BHK 21 cells, which are the author's speciality. It is followed by a lucid and well-documented description by K. W. Jones of *in situ* DNA-RNA hybridisation, a technique which has already yielded valuable information on gene analysis during development. N. G. Maroudas concludes that there is no "best buy" among the different techniques for anchorage-based cell propagation. There is an authoritative chapter by R. G. Miller on cell separation by velocity sedimentation but the excellent theoretical introduction is not matched by sufficient examples of successful or possible applications of the technique. This is followed by the only two chapters on biophysics—one on circular dichroism as a probe for polysaccharide structure and the other on the application of mass spectrometry to protein sequencing. P. L. Pearson's chapter on differential staining of mammalian chromosomes ends with a useful collection of recipes. The last chapter by S. P. Spragg on on-line computers is more useful for information obtained with physical methods than those of cell biology.

Looking at the book as a whole it is difficult to see the rationale for grouping these five methods of cell biology with two physical techniques, particularly as no mention is made of the contents of future volumes. The index is useful and the presentation of text and figures pleasant but the glossary of fourteen cell biology words seems rather pointless. I feel that this book, limited as it is in its scope, will be useful to many biologists, but hope that the next volume will include techniques such as electron microscopic visualisation of genetic transcription or the application of NMR to biological problems.

J. R. Tata

Organic orbitals

The Organic Chemist's Book of Orbitals. By William L. Jorgensen and Lionel Salem. Pp. xii+305. (Academic (Harcourt Brace Jovanovich): New York and London, May 1973.) $11.50.

There is a growing group of organic quantum chemists who believe that the symmetry properties and shapes of orbitals provide the most informative insight into the structure and reactivity of organic molecules. The concern of the authors of this book is to provide the requisite information in the form of electron density contour diagrams for 104 selected molecules of special interest, from hydrogen to norbornadiene. In each case there are three-dimensional computer-produced drawings for the occupied valence orbitals and for at least one unoccupied orbital, together with their group-theoretical symmetry and the orbital energy. These annotated drawings occupy nearly three-quarters of the book. There is a brief introductory account of molecular orbitals and their genesis from bond orbitals and group orbitals. The remaining pages consist of literature references and indications of the computational methods used (*ab initio* with extended basis sets, MINDO/2 or extended Hückel wave functions). The computer programs for the graphical output devices are not given, nor is there any indication of the effort in terms of programming and computer time.

Any chemist with a weakness for computer graphics should enjoy the pretty drawings produced. While not everyone will share completely the authors' enthusiasm for their usefulness, it is perhaps worth remembering that it can be argued that most progress in theoretical organic chemistry has come through the contemplation of three-dimensional atomic arrangements in molecules. The extension of this approach to electrons is therefore within the tradition of mainstream organic chemistry.

V. Gold

Subatomic interactions

The Pion-Nucleon System. By B. H. Bransden and R. G. Moorhouse. Pp. ix+538. (Princeton University: Princeton, July 1973.) $20 boards; $8.95 paper.

Of all elementary particle interactions, the πN system is undoubtedly the one which has been most extensively studied. This has resulted in a wealth of accurate data for pion-induced reactions, and natural accompaniments have been detailed phenomenological studies, model building, and the testing of theories. This is the field of Bransden and Moorhouse's graduate-level book, although it also contains much material (30–40%) about the techniques of hadron physics in general.

The contents, briefly, are as follows. The book opens with a discussion of basic quantities such as isospin, scattering amplitudes and cross-sections. These are illustrated in Chapter 2 by analyses of low-energy πN scattering and pion photoproduction. Chapter 3 is concerned with fixed-t dispersion relations, starting with a field theoretical derivation of forward dispersion relations for spinless particles, and then discussing applications to πN scattering. Analyticity is developed further in Chapter 4, which contains a review of the analytical properties of amplitudes for potential scattering, and then discusses the relativistic πN case, leading to the Mandelstam representation and partial wave dispersion relations. These four chapters are in general clearly written and straightforward, although the discussion of the Mandelstam representation concentrates exclusively on its analytical properties without a warning statement about the asymptotic behaviour necessary for its existence.

Baryon resonances are the subject of the next two chapters. The first, Chapter 5, contains a detailed account of resonance theory, and explains very clearly the general forms of resonant amplitudes and how they arise. The second half of this chapter describes how resonance parameters are deduced from data by phase shift analysis, and gives an assessment of the results that have been obtained. A somewhat surprising omission is the lack of any description of the actual data themselves, not even qualitatively. The second of these chapters, Chapter 6, discusses the classification of resonances in higher symmetries, starting from the isospin group SU(2) and ending with the L-excitation quark model. There is a good physical discussion of group theoretical ideas, and extensive use is made of Young tableaux. Symmetry ideas are also the subject of Chapter 7 on current algebra and its sum rules. Chapter 8 contains a description of higher-energy two-body scattering, and in particular the ideas of Regge poles and duality, and in Chapter 9 the analyticity approach reappears in a review of some attempts at πN dynamical calculations. The final two chapters, 10 and 11, are concerned with πN inelastic scattering, and a detailed discussion of the form factors of the pion and nucleon, respectively. There are two appendices, on angular momentum and the formalism for pion photoproduction.

In reading this book I was conscious of a certain unevenness in the background required of the reader. For example, some knowledge of field theory is required to understand chapters 3 and 7, whereas isospin is (more than once) introduced without assuming any prior knowledge. This is also true of the style. Undoubtedly the best sections of the book are those where the discussion starts from a comparatively low level and the ideas are developed in detail with the necessary full explanation. Chapters 5, 6 and 11 are of this form, and all are excellent. Less successful are those sections where motivation is lacking, or where discussion terminates at an interesting point. An example of the latter is the discussion of resonance poles on page 185. An example of the former is the concept of "signature". I doubt whether someone meeting the idea, as introduced in section 8.4, for the first time would really appreciate its significance. Graduate students may also be alienated by the fact that words are frequently mentioned long before their meaning is explained; for example, "exotic" and "Veneziano model" (or, occasionally, not explained at all). The readers likely to obtain most from this book are thus those with some prior knowledge of strong interaction physics. They are not likely to be disappointed, for almost all aspects of πN physics are discussed. Certainly, all particle physics libraries should possess a copy.

The volume is well produced, and, since there is a paperback edition, not unreasonably priced. There is a considerable number of misprints, but fortunately most of these are trivial. Despite its typed format, it seems to have taken rather a long time to produce (the preface is dated April 1972) with a result that many of the references have been superseded, but that is probably inevitable in an advancing field like particle physics.

B. R. Martin

Embryos and ethics

The Mammalian Fetus in vitro. Edited by C. R. Austin. Pp. xii+388. (Chapman and Hall: London, July 1973.) £8.

THE *in vitro* culture of mouse and rat embryos during the early somite stages of development has little directly in common with the physiological problems of the premature human infant. It is the aim of *The Mammalian Fetus in vitro* to establish a connection by including both in a series of fields of study, each of which overlaps the next. To further this aim, as the editor explains in his introductory chapter, the meaning of the term 'foetus' has been extended backwards and forwards in time somewhat beyond its usual limits.

Culture of post-implantation stages of rodent embryos through the period of organogenesis is described by D. A. T. New, who himself developed most of the relevant techniques. Later organogenesis is particularly inaccessible in placental mammals, but can be studied in marsupials not *in vitro* but in the pouch. In his chapter on marsupial pouch young, G. B. Sharman presents a comprehensive compilation of data on a topic never previously reviewed. D. A. Nixon deals with the physiology of the mid-term foetus and placenta, mainly on the basis of experiments on foetal lambs. The same theme is considered, with particular reference to the development of an artificial placenta, by W. M. Zapol and T. Kolobow on the foetal lamb and by M. C. Macnaughton on the mid-term human foetus. The problems in this field are enormous, and it is abundantly clear that the vitriparity of Aldous Huxley's *Brave New World* is not yet in sight.

Moving on to the viable (or almost so) stage, C. H. M. Walker and B. J. N. Z. Danesh describe their artificial lung–kidney system as used on puppies and human infants, and E. Hey contributes an outstanding chapter on the problems of the premature baby, including respiration, thermoregulation, circulation and nutrition.

Some of the ethical problems involved are discussed in a final chapter, "The Road Ahead", by R. A. McCance. Clearly the enormous strides that have been made in reducing perinatal mortality would have been impossible without extensive experimentation, on human as well as animal material. Sometimes the measures designed to save the lives of infants introduce new and unsuspected hazards: for example, the hundreds of babies suffering retinal damage and subsequent blindness as a result of excessive oxygen treatment in the early 1950s, or the many deaths from "grey baby syndrome" a few years later, due to injudicious treatment with chloramphenicol.

Guidelines for the use of human foetuses for research have been laid down in the 1972 Report of the Advisory Group set up by the College of Obstetricians and Gynaecologists. Different ethical principles apply to viable and to non-viable infants; in the latter case, as also with animal experimentation, the problem is almost as much aesthetic as ethical. McCance regrets that the Advisory Group recommended that foetuses of more than 20 weeks' gestation should be considered viable, since he feels that this creates a "shadowy period of 8 weeks" during which abortions can be performed, yet the use of the abortuses (almost certainly not viable) for experiments of any kind may become illegal. From the point of view of experiments which could involve pain and distress, the cut-off point should surely come earlier: a 19-week foetus, however non-viable, differs from a 6-day blastocyst in possessing all the mechanisms for feeling pain.

One wider ethical point is not considered in this volume. The survival rate of liveborn babies weighing between 1 and 1.5 kg at birth has been pushed up from 50% to 75%, and 20% even of those weighing less than 1 kg may now "expect to survive the neonatal period with expert care". Fortunately, the outlook for survivors has also improved: past reports on babies weighing less than 1.5 kg at birth suggested that more than half would be handicapped, but more recent reports indicate that "with skilled nursing care less than 20% of the survivors will be seriously handicapped". Even this figure makes a disturbingly high contribution to the total burden of physical and mental handicap. Should lung-kidney machines and all the other achievements of foetal and neonatal physiology be used to try to maintain viability in earlier and yet earlier premature infants? If not, where should the line be drawn?

As one might expect from Professor Austin's editorship, the volume is impeccably turned out.

ANNE MCLAREN

View of the brain

The Understanding of the Brain. By John C. Eccles. Pp. xv+238. (McGraw-Hill: New York and London, May 1973.) £1.95.

THIS short book is based upon a series of lectures delivered at Indiana University early last year. Its aim is to provide an outline of recent neurophysiological work of special relevance to our understanding of brain function and, incidentally, to convey the author's somewhat idiosyncratic views on the relations of brain, mind and consciousness.

Professor Eccles makes it clear that his book is to be regarded not as a text or reference work but as a personal communication limited to aspects of the subject which he regards as of particular interest or importance. These aspects are covered in six longish chapters, dealing respectively with neurones and the nerve impulse, peripheral synaptic transmission, synaptic transmission and pathways in the brain, the control of movement, neurogenesis and the neural basis of learning, and finally, brain, speech and consciousness. A list of selected references, mostly recent though certainly not exhaustive, is appended to each chapter.

The material covered in the earlier chapters is presented with the skill and cogency we have come to expect from Professor Eccles; his account of peripheral transmission, in particular, would seem outstandingly well balanced, particularly when his own changes of view over the years are borne in mind. So, too, is the chapter on the central mechanisms of transmission, in which he goes beyond the experimental data in a praiseworthy attempt to formulate general principles governing central nervous activity. Although it is beyond my competence to assess these chapters at an expert level, they seem to me pertinent, well presented and fair.

The chapter on neurogenesis brings together, in a brief compass, much recent experimental material considered in relation to the pioneer work of such men as Weiss and Sperry. The author defends strongly the view that the developing brain can no longer be viewed as a randomly organised structure moulded by use to an appropriate design but rather as a system in which the basic patterns of connection are established prior to their being called into action. This conclusion obviously has important implications for many problems in genetic neurology.

In his account of movement and its control, Professor Eccles has a great deal more to say about the cerebellum than the motor cortex, though he has little use for those who have attempted to understand its functions on the basis of computer models. For this reason, he makes no reference to the work of Marr and others, which many have found extremely stimulating. It is a pity, perhaps, that this whole approach is dismissed so cavalierly.

The final chapter on mind and brain is inevitably controversial. Rightly, the author devotes considerable attention to the work of Sperry on "split-brain" patients. As is well known, a variety of fascinating disconnections between the activities of the two cerebral hemispheres can be demonstrated in these patients, such that each may under appropriate circumstances operate at a high-order level independently of its fellow. Although the right hemisphere seems to be largely, if not wholly, devoid of linguistic expression, it is nonetheless almost certainly unjustified to treat it, as does Professor Eccles, simply as a "computer" lacking any direct liaison with consciousness. No one who has watched a split-brain patient performing complex visual discrimination and recognition tasks processed wholly by the right hemisphere could possibly doubt the presence of consciousness in the sense in which the term is ordinarily used. It is difficult not to suspect that Professor Eccles's view in the matter is governed, in part at least, by extrascientific considerations.

This book has a glossary though no index. It should make stimulating reading for medical students and others seeking a concise and up-to-date account of several important aspects of contemporary neurophysiology. At the same time, its intentionally selective character will obviously limit its usefulness as a formal text. O. L. Zangwill

•

Social wasps and loners

Wasps: An Account of the Biology and Natural History of Solitary and Social Wasps, with Particular Reference to Those of the British Isles. By J. P. Spradbery. Pp. xvi+408 (28 plates). (Sidgwick and Jackson: London, September 1973; University of Washington: Seattle, November 1973.) £8.50; $17.50.

What is a wasp? Dr Spradbery adopts a very narrow definition to include only the members of the Vespoidea, a group which consists of the familiar social wasps and a number of solitary species. In a recent work of very similar title (*The Wasps*, University of Michigan Press, 1970), Evans and Eberhardt take a much wider definition to include all aculeate, or stinging, Hymenoptera, with the exception of the ants and bees. Such a grouping includes the majority of solitary forms (particularly of the Sphecoidea), which have been studied by so many insect ethologists since the early work of J. H. Fabre. Of course, it is quite reasonable to take the more restrictive view, but even Dr Spradbery in his text uses the term frequently in a more general sense.

Taking the Vespoidea then as his group, Dr Spradbery gives us an excellent monographic treatment based mostly on the British species, but with widespread reference to other faunas and to literature otherwise difficult for the non-specialist to obtain. The first part of the book is devoted to a good general discussion of the group, with emphasis on structure and function. There follows a chapter on the solitary species, of the family Eumenidae, concerned mainly with comparative behaviour studies. It is perhaps here that some comparison with the more diverse sphecoid wasps might have been included with advantage. The next eight chapters form the core of the book and are devoted to a thorough review of the behaviour, particularly in terms of nesting, foraging and social organisation, and the population ecology of the British Vespidae, the social wasps.

As would be expected from the author's previous publications, there is a first-class, balanced discussion of many problems, including the controversial field of caste determination. A chapter is devoted to the parasites, predators and commensals associated with wasp colonies. This necessarily is drawn from a wide variety of published records, at least some of which need judging with caution. Chapter twelve is entitled "The Impact of Wasps on Man" and is a useful summary, especially of the sting and its pharmacology. It may come as some surprise to discover that during the period 1949 to 1969, thirty cases were recorded of people in England and Wales who died as a direct result of being stung by wasps! The main part of the book concludes with two chapters of a less detailed nature, which discuss the 800 or so social vespoid species of the world and the possible paths and mechanisms of the evolution of such complex societies.

The book concludes with four very useful appendices. The first is concerned with the taxonomy of the British species and gives good illustrated keys for the identification of the twenty-nine known species. A further appendix gives helpful information on methods of studying, collecting and preserving wasps. The final appendix gives the first published distribution maps for all British species, compiled by the Biological Records Centre, Monks Wood. Clearly these are very incomplete, but their very inadequacy may foster an interest in the group, which is essential for the accumulation of further information.

The standard of line illustrations throughout the book is generally very high. The half-tone plates are in some cases less satisfactory. Most show live wasps or their nests, and others show structural details. A number of good colour plates are included, but those illustrating mounted specimens are rather disappointing. The individual insects are mostly too small to show useful detail and some are very poorly reproduced. Most unfortunately the colour and black-and-white plates are inconsistently laid out, with blank pages interspersed irregularly, for no apparent reason. The legends are often very difficult to associate with the correct figures, and sometimes even hard to find.

In conclusion this is clearly a very valuable and exhaustive work which should be read not only by the small band of research workers interested in wasps, but also by a wider group of general ethologists and ecologists. It will without doubt for long be a standard work in its field.

M. F. Claridge

Straight dislocations

Introduction to Anisotropic Elasticity Theory of Dislocations. By J. W. Steeds. Pp. ix+274. (Clarendon: Oxford; Oxford University: London, May 1973.) £8.35.

In this book Steeds presents a concise, very clearly written account of the elastic theory of straight dislocations in anisotropic media. He concentrates exclusively on those cases whose solution can be analytically expressed, and he shows that these comprise such a large number of cases that the algebraic effort is worthwhile. In short, Steeds 'professionalises' the subject so that a research student with the aid of this book should be able to make intelligent use of anisotropic elasticity, whereas before the book was available most research students (and their supervisors) would founder.

The book contains explicit solutions for a large number of commonly occurring dislocations, and a table at the end lists them so that one can see at a glance whether or not a particular problem is solved. Furthermore, a very clearly written chapter outlines the relationship between the two-dimensional (that is, straight dislocation) solutions and the three-dimensional solutions; it also covers dislocations in uniform motion.

The book is intended to be a reference work, and it has extensive tables of parameters for different crystals. As a reference book, it gains greatly from its clarity and strict deductive approach. As a textbook, it suffers somewhat from these features: students will not easily gain from it a feel for when anisotropic elasticity is important and when it is not; and one would perhaps like guidance on the use of computers to solve some of these problems. In my experience, it is possible to write a computer program which works reliably and which obviates the necessity for algebra or thought—although of course it does not give the kind of insight obtainable from analytic formulae. The computer program itself, however, requires an investment of time which will not pay off unless extensive calculations are envisaged—the one-off calculation is better done by algebra. So there is no doubt that any laboratory concerned with the properties of dislocations should have this book on its library shelves. L. M. Brown

Classified Advertisements

CONDITIONS. All advertisements will only be accepted on the condition that the advertiser warrants that the advertisements do not in any way contravene the provisions of the Trade Descriptions Act 1968 and the Race Relations Act 1968. The Publisher also reserves the right to refuse, amend, withdraw or otherwise deal with all advertisements submitted to him at his absolute discretion and without explanation. All advertisements must comply with the British Code of Advertising Practice.

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes.

Semi-displayed £3.60 per 10 mm. Minimum £7.20, each additional 2 mm 72p. Full page £230.00. Half page across £125.00. 30p is charged for the redirection of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, London, WC2A 2ED. Telephone: 01-242 6264. Telegrams: Textualist, London, W.C.2.

APPOINTMENTS VACANT

university of wales
university college of swansea

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the vacancy of Post-doctoral Research Assistant in the Department of Biochemistry to work on an S.R.C. sponsored research programme concerned with biochemical studies of uracilyl amino acids. Preference will be given to applicants with experience in the isolation of enzyme systems, especially those of plants.

The commencing salary will be on the scale £1,929 to £2,223 per annum plus F.S.S.U. benefits, and the appointment will be for three years from January 1, 1974 or as soon as possible after that date.

Further particulars and application forms may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by **Friday, February 1, 1974.**

(133)

THE OPEN UNIVERSITY

Research Assistant in Earth Sciences

Applications are invited for a post of Research Assistant in Earth Sciences, tenable immediately. The person appointed will work under the supervision of Professor I. G. Gass on Petrochemistry and genesis of volcanic rocks. Applicants should possess a good honours degree in Earth Sciences and postgraduate experience/qualifications in geochemistry. The successful candidate will be given the opportunity to register for a Higher Degree of The Open University.

Further details are available from the Acting Personnel Manager (RE 1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL (Tel. Milton Keynes 74066, extension 3068). Closing date for applications Friday, January 25, 1974. (135)

GLASGOW
COLLEGE OF
TECHNOLOGY

Department of Ophthalmic Optics

Senior Lecturer and Lecturer in Ophthalmic Optics

Applicants should hold degrees or professional qualifications in Ophthalmic Optics. In the case of the Senior Lectureship, a Higher Degree or Higher Diploma together with appropriate experience will be required.

A special interest in clinical aspects, visual optics, ocular pathology or ocular anatomy will be an advantage. Those appointed will be expected to contribute to the development of, and teaching in, areas of ophthalmic study up to Honours degree and post-graduate level.

Members of staff are encouraged to pursue research interests and to read for Higher Degrees.

Salary Scales: Senior Lecturer—Up to £4,023 per annum, depending upon experience, plus £117 per annum for approved teaching training. Lecturer—Up to £3,201 per annum, depending upon experience, plus £117 per annum for approved teaching training.

Application forms and further particulars may be obtained from The Director, Glasgow College of Technology, North Hanover Place, Glasgow G4 0BA, and should be returned as soon as possible. (149)

Faculté des Arts et des Sciences

1. Directeur, Département de physique.
2. Physicien avec Ph.D. ou D.Sc. d'une université reconnue; compétence établie en recherche et préférablement aussi en enseignement; francophone.
3. Direction d'un département de physique groupant actuellement 32 professeurs représentant un assez large éventail des diverses disciplines de la physique; responsabilité de l'enseignement et de la recherche; participation modérée à l'enseignement; supervision des personnels enseignant et non enseignant; animation de la recherche; administration du budget; coordination des activités du département avec celles des autres départements de la Faculté des Arts et des Sciences et de certains départements des autres facultés ou écoles.
4. Traitement proportionnel à la compétence et à l'expérience.
5. M. René de Chantal, doyen de la Faculté des Arts et des Sciences, Université de Montréal, C.P. 6128, Montréal, P.Q., Canada.
6. ler juin 1974 ou avant cette date.
7. ler février 1974.

(150)

DUBLIN INSTITUTE FOR ADVANCED STUDIES

SCHOOL OF THEORETICAL PHYSICS

Applications are invited for a post as Assistant Professor in the School tenable for one or two academic years commencing October 1, 1974.

Salary: £3,091 per annum plus marriage and family allowances.

Applicants should send a curriculum vitae and list of publications, together with the names of two referees, so as to reach the undersigned not later than March 15, 1974.

The Registrar,
Dublin Institute for Advanced Studies,
10 Burlington Road,
Dublin 4, Ireland.

(160)

QUEENSLAND INSTITUTE OF TECHNOLOGY

QUOTE: V.173.73

Applications are invited for the following Senior Academic position.

HEAD OF SCHOOL—APPLIED SCIENCE

Departments have been established within the School to offer degree and/or diploma courses within the following professorial areas.

Applied Chemistry
Applied Geology
Biology and Environmental Science
Computer Science
Mathematics
Paramedical Studies
Physics

The salary for Head of School is currently $19,102 per annum (Professorial level).

Further information may be obtained from the Registrar at the address shown below.

Applications containing full personal particulars, details of qualifications and experience, and the names and addresses of two referees, should be forwarded to the Registrar, Queensland Institute of Technology, P.O. Box 246, North Quay, 4000, by February 2, 1974.

(124)

Head of Animal Supplies

The Research Department, situated in Nottingham, has a vacancy for a person to take full charge of the Animal Supplies and Services Unit, with the responsibility for the breeding, purchase, handling and health of a wide variety of laboratory animals for use in medical research. The Unit, comprising small animal, dog and primate sections, is being enlarged. Extensive new animal facilities are planned and the man appointed will be expected to participate in the development of this project. Staff numbers over 25.

The person appointed is likely to be qualified in veterinary science and may possess experience of laboratory animal husbandry.

Employment conditions are attractive and include profit sharing and contributory pension schemes. Assistance with re-location expenses will be given in appropriate cases.

Please write for further details and application form to: J. F. Pattison, Employment Manager,

Boots
The Boots Company Ltd.,
Station Street, Nottingham NG2 3AA.

(159)

RESEARCH BACTERIOLOGIST

The Union International Co. Ltd., wishes to engage a Research Bacteriologist for the St. Albans Research Centre.

The successful applicant will be required to initiate work on the growth of bacteria for isolation of enzymes acting upon bile acids and other steroids.

Please write, giving full personal and career details, to the Staff Manager (AD 5784), 14 West Smithfield, London, E.C.1.

(103)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

RESEARCH SCHOOL OF PHYSICAL SCIENCES

CHAIR OF MATHEMATICS: The Chair will be an established Chair in the Department formerly held by Professor Kurt Mahler, F.A.A., F.R.S. Other Chairs are held by the Head of the Department, Professor B. H. Neumann, F.A.A., F.R.S., and Professor R. E. Edwards, F.A.A. It is contemplated that the successful applicant will be invited to accept appointment as Head of the Department for a period to be agreed with the Council, following the retirement of Professor Neumann in December 1974. The Department at present has an academic staff of 13. Departments in related fields include the Departments of Applied Mathematics and Theoretical Physics in the Research School of Physical Sciences, the Department of Statistics in the Research School of Social Sciences and the Department of Pure Mathematics in the School of General Studies. In addition, the University Computer Centre has strong interests in numerical analysis. No particular area of research is specified, although it is expected that the appointee will be a recognised authority in one or more branches of pure mathematics.

Closing date: **February 28, 1974.**

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH FELLOWS / POSTDOCTORAL FELLOWS IN GENETICS: Two positions are available in the Department of Genetics (Head: Professor W. Hayes, F.R.S., from January 1974). The successful applicants will work within a group headed by Dr C. H. Doy, in a research programme concerned with the developmental and biochemical genetics of plants.

Work is expected to range from basic and developmental studies with plant cells in culture, to the transfer and expression of genetic information between cells of related and diverse species (plant-plant and plant-microbial hybrids).

Preference will be given for one position to applicants with a background in plant physiology and genetics and for the second position to applicants with a background in molecular biology of plant and/or microbial DNA and its expression.

Closing date: **February 4, 1974.**

Salaries: Salaries for Professor will be $A20,336 per annum. Salary on appointment to other posts will be in accordance with qualifications and experience within the ranges: Research Fellow $A8,698 to $A11,901 per annum (2 by 641; 2 by 640; 1 by 641); Postdoctoral Fellow $A8,698 to $A11,901 per annum. Current exchange rates are approximately $A1=61 NP=$US1.48.

Other conditions: Tenure: Professor to retiring age (at present 65 years); Research Fellow normally for three years in the first instance with possibility of extension to a maximum of five years; Postdoctoral Fellow for not less than one year and not more than two years. Postdoctoral Fellows would normally have recently completed the Ph.D. degree.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation (where applicable) is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF for further particulars before applying. (93)

UNIVERSITÄT ZU KÖLN GERMANY

INSTITUT FÜR GENETIK

E. COLI GENETICIST

A post-doctoral research position for work in association with Professor B. Müller-Hill will be available immediately. The appointment will be for two to three years. The salary will be on the scale of ca. 27,000,— DM per annum.

Applications, with curriculum vitae and the names of two referees, should be sent to Professor B. Müller-Hill, Institut für Genetik der Universität zu Köln, Köln 41, Weyertal 121, West Germany. (25)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOLOGY

ANIMAL TECHNICIAN (GRADE 3) is required by the Department of Biology for the care of small wild animals, including British reptiles.

Duties will include some local field work, giving opportunities to assist with research programmes, and the maintenance of laboratory equipment.

Applicants should preferably have a minimum of one or two years' relevant experience.

The appointment is established with initial salary on the scale £1,650 to £1,920 according to qualifications and experience.

Applications in writing, giving details of age, qualifications and experience and the names and addresses of two referees, should be sent to the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH, as soon as possible. Please quote reference number Na/169/T. (92)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following vacancy:

LECTURER IN ASTRONOMY

in the

DEPARTMENT OF APPLIED MATHEMATICS

Salary range: £1,929 to £4,548. Duties to commence October 1, 1974. Closing date for applications January 31, 1974.

Applications, together with the names and addresses of two referees, should be forwarded to the Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars will be available. Please quote reference 0972.

(85)

LOUGHBOROUGH UNIVERSITY OF TECHNOLOGY

LASER APPLICATION RESEARCH

Applications are invited from qualified physicists, electrical or mechanical engineers for a post as RESEARCH ASSOCIATE to work on S.R.C. sponsored research into laser applications. Some experience is desirable, other relevant experience could include thin film techniques, vacuum deposition methods and optical measurement. The person appointed will work within a laser applications group with an international reputation.

The post, tenable for 2½ years, will carry a commencing salary within the scale £2,058 to £2,718 with F.S.S.U. benefits. Further details and application forms from Mr. F. N. Birkett, Department of Mechanical Engineering.

NEW ZEALAND UNIVERSITY OF CANTERBURY

Christchurch

SENIOR LECTURERS OR LECTURERS IN ZOOLOGY

Applications are invited for the following positions:

MARINE ZOOLOGY. Preference will be given to a marine zoologist with teaching and research experience in some aspect of marine ecology.

ANIMAL BEHAVIOUR. Experience and research interests in some aspect of animal behaviour are necessary. Preference may be given to an applicant interested in invertebrate behaviour.

The salary for Lecturers is on a scale from NZ$6,575 to NZ$8,343 per annum, and for Senior Lecturers NZ$8,489 to NZ$9,963 (bar) NZ$10,259 to NZ$10,846 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **January 31, 1974.** (174)

ELSEVIER SCIENTIFIC PUBLISHING COMPANY

(international publishers of scientific journals and books) has openings in Amsterdam and Oxford for full-time

Editorial Assistants

Description. Preparation of manuscripts for printing, correction of proofs, language correction of contributions written by non-English speaking authors, supervision of freelance workers, responsible and varied work.

Requirements. Degree or equivalent in chemistry, biochemistry, or biomedicine preferred, English mother tongue, meticulous eye for detail.

A good salary according to qualifications and experience, work in a congenial atmosphere, and excellent social security arrangements are offered.

Handwritten applications giving details of education and experience and an indication of salary expected should be addressed to The Personnel Department, Associated Scientific Publishers, P.O. Box 2400, Amsterdam, The Netherlands.

(122)

TROPICAL PRODUCTS INSTITUTE

Animal Nutritionist

. . . to lead small group engaged in assisting developing countries on the better utilisation of animal feed resources and the development of feed manufacturing industries.

The post, in London, will entail travel overseas both to advise governments of developing countries and to undertake project work on animal feed development.

Candidates (aged at least 25 and normally under 32) should have a 1st or 2nd class honours degree, or equivalent, in a relevant subject, and have at least four years' postgraduate experience. Practical experience in the analysis of feed materials an advantage, and experience of applied animal nutrition essential.

Appointment will be as Senior Scientific Officer (£2,790–£3,815).

Application forms (to be returned by 1 February 1974) from Miss C. A. Hall, Administrative Secretariat, Tropical Products Institute, 127 Clerkenwell Road, London EC1; please quote SA/10/JD.

(82)

LIVERPOOL REGIONAL CARDIAC CENTRE

SEFTON GENERAL HOSPITAL, Liverpool L15 2HE

Applications are invited for the post of

BIOCHEMIST

(Basic Grade, Probationary or Post Probationary) in the Research Laboratory of the Liverpool Regional Cardiac Centre. The work of the laboratory covers research into all aspects of heart disease with particular emphasis on coronary artery disease.

Opportunities exist for studying for a higher qualification. The appointment will be subject to the Whitley Council terms and conditions of service.

Enquiries should be made initially to Dr T. Deegan, at the above address (Tel. 051-733 4020 ext. 311). Application form obtainable from the Acting Secretary, The United Liverpool Hospitals, 80 Rodney Street, Liverpool L1 9AP, to be returned by January 25, 1974. (79)

UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE

Chair of Rehabilitation Studies

The University Court invites applications for the Chair of Rehabilitation Studies which has been established by means of gifts from the National Fund for Research into Crippling Diseases and the Thistle Foundation. The Chair has been founded primarily to foster research in the many aspects of rehabilitation. It is confidently expected, however, that the involvement of the Professor and his colleagues in undergraduate and postgraduate education will lead to a greater realisation within the health professions and the community of the importance of rehabilitation and resettlement after all forms of illness and disability.

The Professor is initially to be accommodated within the Department of Orthopaedic Surgery but is in no sense restricted to the problems of locomotor rehabilitation.

The appointment will be made in association with the South-Eastern Regional Hospital (Scotland) Board (or its successors from 1st April, 1974) who have undertaken to fund two consultant posts in rehabilitation medicine and supporting staff.

Applications will be welcomed from candidates in any discipline within the health professions. It is hoped that the Professor will be able to take up office by October, 1974.

The stipend of the Professor will be £7,599 per annum, and membership of F.S.S.U. will be required.

Further particulars and terms of appointment may be obtained from the undersigned to whom applications (16 copies), giving the names of three persons to whom reference may be made, should be lodged not later than 16th March, 1974.

Secretary to the University,
University of Edinburgh,
Old College,
South Bridge,
Edinburgh EH8 9YL

(126)

GLASSHOUSE CROPS RESEARCH INSTITUTE

Applications are invited for the following posts:

1. **Two SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICERS in PLANT BREEDING DEPARTMENT** for work on vegetable crops. Good honours degree required in a biological subject with specialisation in genetics, coupled with plant pathology or plant physiology. These posts are being re-advertised. Closing date February 14.

2. **One HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER in BIOCHEMISTRY AND CROP PROTECTION DEPARTMENT** to lead team working on growth regulating substances. Applicants should have good honours degree or equivalent qualification in plant chemistry or other appropriate subject with at least two years' post-graduate research or development experience. At least four years relevant post-graduate research or development experience required for appointment to SSO grade. Closing date February 21.

Salary scales: £1,590–£2,177 (SO); £2,076–£2,667 (HSO); £2,615–£3,640 (SSO); Additional non-pensionable allowance of 4¼% of gross salary to offset superannuation contributions.

Further details obtainable from Secretary of the Institute, Worthing Road, Rustington, Littlehampton, Sussex, to whom applications should be sent, giving full biographical details and the names and addresses of two referees.

(165)

Horticultural Inspector

Scotland £3377-£4057

for work in connection with schemes relating to improvement, business grants, fruit certification and bulb inspection and to carry out import and export plant inspection, horticultural surveys and liaison with various horticultural organisations and outside interests.

Candidates (aged at least 26) should, preferably, have a degree or national diploma in Horticulture together with practical knowledge and experience of commercial horticulture. Specialist knowledge of fruit and bulb production and a working knowledge of Government grant-aided schemes would be an advantage. Ability to drive a car essential.

Starting salary £3,377 on a scale rising to £4,057. Prospects of promotion. Non-contributory pension scheme.

For full details and an application form (to be returned by February 1, 1973), write to Scottish Office, Personnel Division, St. Andrew's House, Edinburgh EH1 3BX quoting S/8499.

Department of Agriculture and Fisheries for Scotland

(158)

UNIVERSITY OF THE ORANGE FREE STATE

C.S.I.R. FLAVONOID RESEARCH UNIT

RESEARCH ASSISTANTSHIP

Applications are invited for the above vacancy in the Department of Organic Chemistry tenable over a period of up to 3 years. The work involves postgraduate research in all branches of flavonoid and tannin chemistry leading to M.Sc. or Ph.D. degrees, according to initial qualification. Preference will be given to candidates for the Ph.D. degree. The position should be assumed as soon as possible after January 1, 1974.

Minimum initial salary with M.Sc. qualification: R3,000; B.Sc.(Hons.) R2,500.

Applications, giving details of academic record and curriculum vitae should be posted to Professor D. G. Roux, Department of Chemistry, University of the Orange Free State, P.O. Box 339, Bloemfontein, South Africa. (31)

UNIVERSITY OF ZAMBIA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN PHARMACOLOGY in the School of Medicine. Duties will include the teaching of physiological pharmacology to pre-clinical students, organisation of the practical work, teaching of chemotherapy to clinical students and the carrying out of pharmacological research of relevance to the continent. Appointee will be required to take up duties as soon as possible. Salary scales: Senior Lecturer K5,600 to K6,600 per annum. Lecturer K4.000 to K5,400 per annum. There is a medical supplementation of K1,200 per annum (£1 sterling=K1.50.) The British Government may supplement salaries in range £200 to £500 per annum (sterling) for married appointees, or £100 to £200 per annum (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation and medical aid schemes; regular overseas leave.

Detailed applications (two copies), including a curriculum vitae and naming three referees, should be forwarded by airmail, not later than January 26, 1974, to the Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (173)

UNIVERSITY COLLEGE, DUBLIN

DEPARTMENT OF GEOLOGY

COLLEGE LECTURER
or
ASSISTANT LECTURER

Applications are invited for the above post by geologists with specialist qualifications in Sedimentary Petrology and Stratigraphy.

The essential requirements are a Doctorate, together with adequate experience and research accomplishments, and the names of two referees with personal knowledge of the applicants must be submitted.

Salary scale: College Lecturer: £3,232 by £154 to £4,310; Assistant Lecturer: £2,195 by £122 to £3,049. Non-contributory pension and family allowances are additional to salary.

Applications should be made before February 1, 1974, to J. P. MacHale, Secretary and Bursar, University College, Belfield, Dublin, from whom further details may be obtained. (156)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF MEDICINE
(LEEDS GENERAL INFIRMARY)

Applications are invited for the post of RESEARCH ASSISTANT in MYCOLOGY in the dermatology section of the department. The successful candidate will take part in studies on the epidemiology and pathogenesis of Candida infections. Applicants should have a degree in Microbiology or a related subject. The appointment will be made for one year in the first instance, and it is hoped that the successful candidate will take up the appointment as soon as possible. Starting salary £1,449 (with F.S.S.U. benefits).

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote reference 50/5/D). Closing date January 31, 1974. (172)

Research Unit on the Spatial Structure of Biopolymers

A research unit on the spatial structure of ribosomes and their components is to be established at the Max-Planck-Institut für Molekulare Genetik in Berlin-Dahlem, with the financial support of the Deutsche Forschungsgemeinschaft.

Applications are invited for the positions of the head of this research unit and for scientists working in the unit. The annual salary for the head will be approximately 45-50,000 DM and for the scientists 32-42,000 DM. The initial appointment will be for three years with the possibility of extension.

Applicants should have experience in one of the following fields: Crystallization of proteins or nucleic acids, X-ray crystallography of biopolymers, chemistry of proteins or nucleic acids. It is not necessary for the applicants to be German.

Applications should be sent before March 30, 1974, to Professor H. G. Wittmann, Max-Planck-Institut für Molekulare Genetik, Ihnestrasse 63-73, D-1000 Berlin 33, Germany.

(112)

UNIVERSITY OF OTAGO

FACULTY OF MEDICINE

THE CHRISTCHURCH CLINICAL SCHOOL

CHRISTCHURCH, NEW ZEALAND

RESEARCH OFFICER/ SENIOR RESEARCH OFFICER

Applications are invited from suitably qualified persons for the position of Research Officer in the Department of Surgery within the Faculty of Medicine.

Applicants should hold a Ph.D. or its equivalent and postdoctoral research experience is desirable. Applicants should have a sound scientific background and preferably some experience within the broad field of transplantation and tumour immunobiology.

Salary scale: Research Officer NZ$5,985 to NZ$8,343 per annum.

A particularly well-qualified candidate could be appointed at the level of Senior Research Officer on a salary scale ranging from NZ$8,489 to NZ$10,846 per annum, with a bar at NZ$9,963 per annum. Salary scales are subject to both triennial review and cost-of-living adjustments.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, P.O. Box 56, Dunedin, New Zealand. Particular enquiries concerning the position may be addressed to Professor W. A. A. G. Macbeth, Department of Surgery, Christchurch Clinical School, Christchurch Hospital, Private Bag, Christchurch, New Zealand.

Applications close in London and in New Zealand in **January 31, 1974.** (98)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GENETICS

Applications are invited for the post of LECTURER IN POPULATION GENETICS in the Department of Genetics.

Initial salary within the range £1,929 to £4,548 per annum, according to qualifications and experience.

The post is tenable from October 1, 1974.

Applications, together with the names of three referees, should be received not later than February 27, 1974, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/N/80640. (129)

UNIVERSITY OF WARWICK

RESEARCH TECHNICIAN GRADE 3

The Department of Biological Sciences has a vacancy for a permanent post in the research laboratories. The person appointed will work on the biochemistry of proteins and nucleic acids, under the direct supervision of a member of the academic staff.

Applications in writing to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 19/2T/73, as soon as possible. (87)

GOVERNMENT OF FIJI

HYDROLOGIST

Required for the Public Works Department for one tour of 30/36 months' initially. Salary including TAX FREE SUPPLEMENT will be in the range £2,180–£3,180 a year according to qualifications and experience. Other benefits include a substantial gratuity, free passages, liberal leave on full salary, generous education allowances and Government quarters at moderate rental. An appointment grant £200, car advance £600 and packing expenses £60 may be payable.

Candidates MUST have a wide experience ranging over 10 years in general hydrological works, with particular emphasis on the collection, collation and evaluation of rainfall and run-off data, and the location and establishment of hydrological stations.

Because of lower rates of income tax in Fiji, the gross emoluments are roughly equivalent to UK salaries of

£3,200 to £4,600 for a single man

£3,400 to £4,800 for a married man with 2 children

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Overseas Development Administration of the Foreign and Commonwealth Office.

For further particulars you should apply, giving brief details of experience to:

crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number M3F/730217/NF.

(147)

MINISTRY OF AGRICULTURE FISHERIES AND FOOD LONDON

CHIEF SCIENTIST'S GROUP

ASSISTANT RESEARCH LIAISON OFFICERS

There are vacancies at SCIENTIFIC OFFICER level in the Chief Scientist's Group which is responsible for providing scientific advice to the Ministry on policy matters relating to agriculture, horticulture and food science, for framing, commissioning and reviewing the Ministry's research and development programme and for keeping in touch with R and D work in the UK and overseas.

The disciplines involved are Animal Husbandry, Arable Crops and Plant Science, Horticulture, Agricultural Engineering, and Food Science and Technology.

The appointment will be for a period of three years. Duties include general scientific support to the Research Liaison Officers (Senior Principal Scientific Officers): drafting papers for R and D Boards and Committees of the Joint Consultative Organisation: preparation and evaluation of statistical information and interpretation of reports, data, scientific papers and computer printouts: visits to Research establishments, NO laboratory work.

QUALIFICATIONS: University Degree, HNC or equivalent qualification in an appropriate scientific subject.

AGE: Normally under 27 years but older candidates will be considered.

SALARY SCALE: £1,318 to £1,402 to £1,499 to £1,590 by nine increments to £2,177 plus £175 per annum. Inner London Weighting. Starting salary determined on basis of qualifications and experience.

APPLICATIONS: Fuller details of the posts and application forms are available from Mrs. M. Lyn-Cook, Ministry of Agriculture, Fisheries and Food, Room 625, Great Westminster House, Horseferry Road, London SW1P 2AE. Telephone No. 01-834 8511 Extn. 6449 or 6244. Closing date for completed applications January 23, 1974.

(142)

Warrnambool Institute of Advanced Education

Post Office Box 423,
Warrnambool 3280
Victoria, Australia

The Institute is a Regional College of Advanced Education providing diploma courses in applied science, art, business studies, engineering and social science. A degree course in business will be introduced in 1974. A degree course in social science is at an advanced planning stage. Other degree courses and courses in teacher education will be introduced as soon as possible.

Plans are now being prepared for complete relocation on a 150-acre site. The first residence buildings on the new site were occupied in February, 1973.

HEAD. OF SCHOOL/DIVISION

(Two Positions)

1. Division of Applied Science and Engineering.
2. Division of Business Studies, General Studies (including Social Science) and Art and Design.

SALARY: $19,102 per annum.

DUTIES: Each head will be responsible to the principal for the administration of his division. He will be expected to provide academic leadership and enrichment by teaching, investigation and publication in his discipline. He will be expected to work in collaboration with heads of faculty and other staff for the maintenance and advancement of the academic programme of the Institute.

QUALIFICATIONS: Recognised scholarship together with a higher degree or equivalent in or related to one or more of the disciplines of the division.

At least 15 years' relevant professional experience, including some experience in tertiary education.

Ability and experience in the development and administration of academic programmes.

APPLICATION: Prospective applicants should obtain further particulars from the Academic Registrar.

Applicants will be expected to include particulars of qualifications, experience and present position, together with the names of three referees.

Applications close with the Academic Registrar on Monday, February 18, 1974.

(123)

UNIVERSITY OF ABERDEEN

RESEARCH ASSISTANTSHIP IN CHEMISTRY

Applications are invited for above post for work on organic reactive intermediates in collaboration with Dr A. R. Forrester. Salary £1,896 per annum; appointment for one year only.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) giving the names of two referees should be lodged as soon as possible. (125)

MARINE SCIENCE TEAM

Geological Oceanographer-Geophysicist, Ph.D., 20 years' experience in continental shelf exploration, research and teaching, with numerous publications and some patents pending, and **Biological Oceanographer,** M.Sc., specialist in marine microbiology and pollution, presently teaching and operating own research vessel in the eastern Mediterranean, are interested in becoming associated with an aggressive, developing research, academic or industrial organisation, preferably Europe or Mediterranean area.—Write Box 2079, Nature, T. G. Scott & Son Ltd., Clement's Inn, London WC2A 2ED. (7)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

Applications are invited for the post of

LECTURER IN VIROLOGY

(in the Department of Medical Microbiology)

Preference will be given to those with medical degrees.

Salary scale: (a) £3,012 to £4,668 (Clinical); (b) £1,929 to £4,548 (Non-clinical) plus £162 London allowance.

The School provides a routine hospital diagnostic service and the successful candidate will be expected to participate in this work as well as undertaking research and teaching. The hospital has its own infectious diseases unit and there are excellent opportunities for gaining wide experience in clinical virology, as well as in diagnostic bacteriology both in the Department and in the associated Public Health Laboratories.

Applications, including curriculum vitae and names and addresses of two referees, to the Dean, St. George's Hospital Medical School, Blackshaw Road, Tooting, London SW17 0QT, before February 8.

The Virology Unit is at Hyde Park Corner and may be visited by arrangement with Professor H. Stern. (119)

MONASH UNIVERSITY

MELBOURNE, AUSTRALIA

DEPARTMENT OF PHYSICS

LECTURER

Applications are invited from experimental physicists with a research interest in one of the following areas: low temperature physics (helium studies, nuclear orientation and superconductivity), laser studies, spectroscopy (Mössbauer, ESR, NMR, optical), fundamental magnetic, electrical and structural studies of matter including polymers, minerals and biological materials.

The Department which has 72 staff members, is well equipped for research in these areas and has good technical services including mechanical and electronics work-shops, materials preparation, computing and photographic facilities.

Salary scale: $A8,698 to $A11,982 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5 per cent and 10 per cent respectively.

Benefits: Travelling expenses for appointee and family; removal allowance; repatriation after three years' appointment if desired; temporary housing for an initial period. Study leave entitlement accumulates at the rate of one month's leave for each six months' service up to six years, with provision for financial assistance.

Further general information and details of application procedures are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia, or the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. Technical enquiries should be addressed to Professor R. Street, in the University.

Closing date: **February 22, 1974.**

The University reserves the right to make no appointment or to appoint by invitation. (101)

ROYAL POSTGRADUATE MEDICAL SCHOOL

SCIENTIFIC OFFICER (Graduate in Biochemistry, Chemistry or Biological Sciences) required to assist research biochemist investigating prostatic tissue. Training given in advanced laboratory techniques The research project involved may yield material suitable for submission for a higher degree. Salary not less than £1,812 per annum.

Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS, quoting ref. no. 3/326/N. (141)

PERSONAL ASSISTANT/ SECRETARY

Graduate, required by the Director of Research and Managing Director. Shorthand or audio-typing essential. An interest and some basic training in Scientific/Medical subjects essential. Company engaged in Drug Research. Very interesting work and excellent conditions, with pension and assurance scheme in operation.

Apply BIOREX Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (167)

The University of Leeds
DEPARTMENT OF PHYSICS

Applications are invited for the vacant CHAIR of Theoretical Physics in the Department of Physics. The salary will be not less than £5,625 per annum and the appointment will be made from a date to be arranged with the successful candidate. The University reserves the right to consider for appointment persons other than those who submit formal applications.

Applications (two copies) stating age, qualifications and experience naming three referees, should reach the Registrar, The University, Leeds LS2 9JT (from whom further particulars may be obtained), quoting the reference number 22/13/D, not later than March 4, 1974. Applicants from overseas may apply in the first instance by cable naming three referees who should preferably be in the United Kingdom. (120)

UNIVERSITY OF BOTSWANA, LESOTHO AND SWAZILAND

Applications are invited for the following post:

CHAIR OF MATHEMATICS. The University is seeking a versatile mathematician with interests in undergraduate teaching and research relevant to the needs of the three developing countries it serves. A particular interest in the development of courses appropriate to middle-level manpower training would be welcomed. Two years of the University's four-year post-O-level programme are at present taught in all three countries. The full programme in Mathematics is at present offered only in Lesotho and the Chair is likely to be tenable on the Lesotho campus.

The appointment will be on contract for limited periods, normally for three years in the first instance. Appointee will be expected to assume duty by July 1, 1974, or as soon as possible thereafter. Salary scale: R5,880 to R6,420 per annum (£1 sterling=R1.55). A 25 per cent gratuity is paid in lieu of superannuation. The British Government may supplement salary by £1,000 per annum (sterling) for married appointee or £600 per annum (sterling) for single appointee (normally free of all tax) and provide children's holiday visit passages. Education allowance; medical scheme; accommodation at reasonable rents; family passages; biennial overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees should be forwarded by air mail, not later than January 30, 1974, to the Registrar, University of Botswana, Lesotho and Swaziland, Roma, Lesotho, Africa. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars of the appointment may be obtained from either address. (137)

SUNDERLAND POLYTECHNIC
DEPARTMENT OF MINING

Applications are invited for the post of

CURATOR

N.J.C., A.P.T. & C. Staff T4 (£1,644 to £1,926) in Geology in the Mining Department. Candidates should either be graduates or have wide experience in Geology.

Applications are restricted to Local Government Officers in England and Wales (excluding London).

An application form and further particulars can be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD. The form should be returned by January 25, 1974. (102)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS
DEPARTMENT OF APPLIED BIOLOGY
DOWNING STREET, CAMBRIDGE

Duties: Duties include preparation and editing of abstracts for the journal *Plant Breeding Abstracts*, which covers world literature on plant breeding and genetics.

Qualifications: Applicants should have a degree in botany, agriculture or genetics. A knowledge of or aptitude for foreign languages would serve as an additional qualification. An ability to write good English is essential.

Salary: In the scale £1,318 to £2,422 (bar) to £2,615 to £3,250 (bar) to £3,510 to £3,742, plus a compensatory allowance (taxable but not superannuable) of 4½ per cent to offset personal contribution to F.S.S.U. Starting salary according to qualifications, experience and age.

Application forms and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: January 31, 1974. (104)

AUSTRALIA
Public Service of Victoria
Ministry for Conservation
Fisheries and Wildlife Division

Research Officer

Ref. No. (P/01)

TWO POSITIONS

Yearly Salary: $A6,229 minimum; $A10,674 maximum. (Generally appointment will be within the salary range $A6,229 to $A8,981 according to qualifications and experience, but applicants possessing special qualifications or extensive experience may be considered for appointment to the range $A9,151 to $A10,674).

POSITION NO. 1

Duties: To carry out field and laboratory studies in marine primary productivity and energetics in relation to water quality characteristics; other research duties as directed.

Qualifications: An approved degree in Science with appropriate training in Botany; appropriate training and experience as related to primary productivity and energetics is desirable. Experience with productivity of higher plants an advantage.

POSITION NO. 2

Marine Invertebrate Zoologist, Western Port Bay Environmental Study

Dutes: As a Marine Invertebrate Zoologist to conduct investigations into the quantitative ecology of Westernport Bay with a view to assessing the effects of industrial and domestic development in the area; other research duties as directed.

Qualifications: An approved degree in Science with Zoology as a major; appropriate training and experience in the taxonomy of polychaetes.

Note: Separate applications must be submitted for these positions.

Applications should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, 1 Treasury Place, Melbourne, 3002, Australia, quoting reference number (P/01), not later than Tuesday, January 29, 1974, together with statements of experience and qualifications and date and place of birth. (105)

UNIVERSITY COLLEGE, DUBLIN
GEOLOGY DEPARTMENT
RESEARCH ASSISTANTS
1973–4 SESSION

Applications are invited for a Research Assistantship in the current session, with the possibility of re-appointment in the two succeeding sessions. The Assistants will be required to carry out research on the Igneous and Metamorphic Geology of the Leinster Massif, under the sponsorship of the National Science Council of Ireland.

The essential requirement is a good Honours degree in Geology and preference will be given to candidates with ability to conduct research, and with experience in XRF work. Successful applicants who do not hold doctorate degrees will be expected to register for a Ph.D. of the National University of Ireland.

Salary: approximately £900 per annum.

Applications must be submitted before January 31, 1974, but appointments may be made before that date.

Apply to: the Secretary, Department of Geology, University College, Stillorgan Road, Belfield, Dublin 4. (157)

UNIVERSITY OF OTAGO
DUNEDIN, NEW ZEALAND
LECTURER OR SENIOR LECTURER IN MICROBIOLOGY

The Council of the University of Otago, Dunedin, New Zealand, invites applications from Science graduates for an appointment as Lecturer or Senior Lecturer in the Department of Microbiology in the Medical School.

Salary: According to qualifications and experience: Lecturer: NZ$6,575 to NZ$8,343 per annum; Senior Lecturer: NZ$8,489 to NZ$10,846 per annum with a bar at NZ$9,963 per annum.

Further information may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, from Professor J. A. R. Miles, Department of Microbiology, University of Otago Medical School, P.O. Box 913, Dunedin, New Zealand, or from the Registrar of the University, P.O. Box 56, Dunedin, New Zealand.

Applications close in London and in New Zealand on **February 9, 1974.** (99)

OPPORTUNITIES IN FORENSIC SCIENCE

Chemists and Biologists graduating this year or completing a post-graduate course

Science has important contributions to make to the administration of justice and the investigation of crime. The Forensic Science Service is expanding to meet increasing police demands and to take advantage of current scientific developments.

Vacancies are expected in the regional laboratories, where the young scientist will at first assist experienced colleagues and later assume responsibility for examining material associated with crime, preparing reports and giving evidence in court. Posts should also become available in the Central Research Establishment at Aldermaston which provides R & D facilities, central analytical services and computer based information retrieval.

Appointment will be as Higher Scientific Officer (£2076-£2667) or Scientific Officer (£1318-£2177), depending on age, qualifications and experience. Starting salary may be above the minimum of the scale at each level.

A degree/HNC/HND in an appropriate subject is essential. For HSO at least 2 years postgraduate experience is necessary, and candidates should normally be aged under 30. For SO they must be under 27.

For further details and an application form (to be returned by 1st February 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB or telephone Basingstoke 29222 Ext 500 or London 01-839 1992 (24 hour answering service). Please quote: SB/7/LA.

Home Office

(162)

UNIVERSITY OF KENT AT CANTERBURY

RESEARCH ASSISTANT IN THE BIOLOGICAL LABORATORY

A RESEARCH ASSISTANT is required for metabolic studies of biodegradation of detergent compounds by bacteria. Applicants should have either a degree in microbiology, or alternatively, in biochemistry with some experience in the handling of micro-organisms. Salary range £1,311 to £1,497.

Applications with full details of qualifications and experience and with the names of two referees to the Assistant Registrar, Faculty of Natural Sciences, The University, Canterbury, Kent, by January 16, 1974, quoting Ref. A45/73. (109)

UNIVERSITY OF MANCHESTER

RESEARCH ASSISTANT IN THE DEPARTMENT OF CHILD HEALTH

Applications invited for this post from graduates, preferably with post-doctoral experience, to work on tissue culture of endocrine pancreas. Experience in cell biology, endocrinology or biochemistry an advantage. Appointment is for two years from March 1, 1974. Salary range £2,718 to £3,048 per annum. F.S.S.U.

Particulars and application forms (returnable by January 18, 1974) from Dr. R. D. G. Milner, St. Mary's Hospital, Manchester M13 0JH. (60)

UNIVERSITY OF EXETER

DEPARTMENT OF MATHEMATICS

N.E.R.C. RESEARCH ASSISTANTSHIP

Applications are invited from suitably qualified candidates for the post of Research Assistant in the Department of Mathematics. The post is tenable initially for a two-year period (approximately) from the date of appointment; the work is concerned with numerical mathematical modelling of large-scale flow in the atmosphere, and is a research project supported by N.E.R.C. under the direction of Professor D. R. Davies. Candidates should be graduates with qualifications in Mathematics or in Meteorology.

Salary scale: £1,398-£1,482-£1,578 with F.S.S.U. benefits.

Further particulars may be obtained from the Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ, to whom applications giving the names of two referees, should be forwarded (4 copies; overseas candidates 1 copy) by February 23. Please quote Ref.: 1/62/7063. (88)

IMMUNOLOGICAL TECHNICIAN

required to work on various aspects of cell mediated immunity. Salary on Whitley Council scale for Medical Laboratory Technicians, i.e., £1,440-£2,292 per annum, plus £126 L.W.

Applications and enquiries to: Dr H. E. Amos, Department of Immunology, Institute of Dermatology, St. John's Hospital for Diseases of the Skin, Homerton Grove, London E9 6BX. Tel.: 01-985 7061. (89)

CROSS INFECTION REFERENCE LABORATORY

We have a vacancy for a Technician or Senior Technician in the Streptococcus Laboratory. This post would be suitable for a candidate who is working for the I.M.L.T. Special Examination. Graduates may apply for this position. Salary according to qualifications and experience, National Health Service terms and conditions of service and superannuation.

Applications to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT, stating age, qualifications and experience and names and addresses of two referees. (134)

UNIVERSITY OF OXFORD

Applications are invited for a post of UNIVERSITY LECTURER IN THEORETICAL PHYSICS from October 1, 1974, at a salary on the scale £1,929 per annum (at the age of 24 or under) to £4,863 per annum (at the age of 42 or over).

The lecturer will be expected to participate in the teaching and research work of the Department of Theoretical Physics.

The successful candidate may be elected, if a man, to a Fellowship at St. John's College, or if a woman, to a Fellowship at Somerville College. Details of the college duties and stipends may be obtained from the Senior Tutor of St. John's College or the Principal of Somerville College, but no separate application for a College Fellowship need be made.

Further particulars may be obtained from Professor Sir Rudolf Peierls, Department of Theoretical Physics, 12 Parks Road, Oxford OX1 3PQ, to whom applications (5 copies, except from overseas applicants) should be sent by February 2, 1974. (95)

UNIVERSITY OF OXFORD

DEMONSTRATORSHIP IN DEVELOPMENTAL BIOLOGY

The Lincare Professor of Zoology proposes to appoint, on or before September 1, 1974, a Departmental Demonstrator in Developmental Biology. The salary will be on a scale rising to £2,283 (with F.S.J.M.).

It is hoped that the Demonstrator will cooperate with Dr R. L. Gardner and Dr C. F. Graham in the teaching of Reproduction and Developmental Biology. Research facilities are available for the Demonstrator.

Applications (if possible, seven copies, except in the case of overseas applicants who need only submit one copy) should be sent to Professor J. W. S. Pringle, Department of Zoology, South Parks Road, Oxford OX1 3PS, not later than February 28. They should include a statement of age, qualifications and experience, and the names of two referees. (106)

PAHLAVI UNIVERSITY

COLLEGE OF ARTS AND SCIENCES
SHIRAZ, IRAN

Applications are invited for positions in Astronomy and Physics beginning fall 1974, at the ASSISTANT/ASSOCIATE PROFESSOR level. Duties include teaching B.Sc. and M.Sc. students and some research. Field of solid state, nuclear, and astrophysics are represented in the department. A Varian X-band E.P.R. Spectrometer is in operation, and a 20-inch Cassegrain reflector with a photoelectric photometer is expected to be in operation by July 1974.

Ph.D. is required. Appointments will be made on a two-year renewable contract basis with an annual salary range equivalent to $12,000 to $16,000 depending on qualifications and experience. Return fare included.

Send résumé, curriculum vitae and confidential recommendations from three references to Dean Vessal, from whom particulars may be obtained. Deadline for applications is April 1, 1974. (107)

ST. BARTHOLOMEW'S HOSPITAL

LONDON, E.C.1

GASTROENTEROLOGY ASSISTANT required to help and supervise patients for investigations. Medical qualifications not necessary.

Salary scale £708 to £1,335 per annum plus £126 London Weighting.

Please apply in writing to the Personnel Officer, quoting ASC/3872/N. (108)

WESTERN AUSTRALIA KINGS PARK BOARD

invites applications for the position of RESEARCH OFFICER. Applicants should hold preferably a higher degree in Botany, Horticulture or a related subject. The appointee will be required to participate in a programme of research under the supervision of the Director on the nutrition and environmental requirements, germination, growth, reproduction and dispersal mechanisms of native plants.

The appointment is subject to the conditions of the State Public Service and the present salary range is $A6,767 to $A9,263 per annum.

Further information concerning King's Park and Botanic Garden or the position of Research Officer may be obtained from the Board. Applications, including details of the applicant's career, qualifications and the names and addresses of two referees (please do not send original certificates or testimonials) should reach the Director not later than January 31, 1974, Kings Park Board, West Perth, Western Australia 6005. (148)

HOUGHTON POULTRY RESEARCH STATION

Applications are invited for the post of

SENIOR VETERINARY RESEARCH OFFICER
OR
PRINCIPAL VETERINARY RESEARCH OFFICER

Applications are invited for a virologist with veterinary qualifications to be responsible for the study of avian respiratory viruses. The appointment will be made within either the Senior Veterinary Research Officer scale (£3,095 by 7 to £3,742) or the Principal Veterinary Research Officer scale (£3,963 by 6 to £5,202) depending upon qualifications and experience.

F.S.S.U. superannuation, membership of which attracts a non-pensionable allowance of 4½ per cent of salary.

Further particulars and application forms available from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon PE17 2DA. Closing date for applications February 11, 1974. (14)

UNIVERSITY OF EDINBURGH

TECHNICAL OFFICER ELECTRON MICROSCOPY

Required for the Department of Botany; to be responsible for the operation of the microscope and for assisting and advising research staff on electron microscope techniques. Applicants should be suitably qualified and familiar with the preparation of material for electron microscopy, particularly in ultramicrotomy. Salary range £2,007 to £2,382 per annum. Ref. no. T5305.

Written applications, quoting the post reference number, should be addressed to the Personnel Officer, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS. Telephone number 031-667 1011, ext. 4325. (116)

THE UNIVERSITY OF ADELAIDE

DEPARTMENT OF PHYSICAL AND INORGANIC CHEMISTRY

TEACHING FELLOWS

Applications are invited for Teaching Fellows who should have a Ph.D. degree in either Physical or Inorganic Chemistry. Half of his time will be devoted to teaching and half to research. A document detailing research interests of the Department will be sent on application.

Salary scale: $A7,270 by $A286 (3) by $A285 (2) to $A8,698. Initial salary will be fixed in relation to qualifications and previous experience. No provision is made for superannuation.

Further information, including list of particulars required of an applicant, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Registrar, G.P.O. Box 498, Adelaide, S.A. 5001, not later than **February 1, 1974.** (136)

NATIONAL INSTITUTE FOR BIOLOGICAL STANDARDS AND CONTROL

HAMPSTEAD, LONDON

JUNIOR TECHNICAL OFFICER/TECHNICIAN required in the Antibiotics Division to work in a laboratory concerned with the evaluation and control of antibiotics used in therapy. Candidates should possess a degree/HNC or equivalent in one of the biological sciences. Graduates will be appointed to the Junior Technical Officer scale between £1,533 to £2,199 per annum. Holders of HNC of the equivalent will be appointed to the Technician grade, £1,566 to £2,418 per annum. Experience in antibiotic assay by microbiological and chemical procedures is desirable.—Please apply with details of age, qualifications and experience to Mr P. A. Collingridge, National Institute for Medical Research, The Ridgeway, Mill Hill, NW7 1AA. Tel.: 959 3666. (131)

Battelle

Geneva Research Centre

Seeks urgently

BIOCHEMIST

With previous experience in cell surfaces (immunology, microelectro-phoresis).

—Comprehensive social security scheme
—Four weeks annual vacation
—Assistance with finding accommodation

Applicants should send curriculum vitae, photograph and salary requirements to:—

The Personnel Manager,
Battelle Geneva Research Centre,
7 route de Drize,
1227 Carouge/Geneva, Switzerland. (171)

WESTERN REGIONAL HOSPITAL BOARD

Department of Clinical Physics and Bio-Engineering

Senior Grade Physicist and Electronic Engineer

Applications are invited from graduates with first or second class honours in physics or electrical engineering and at least four years of relevant postgraduate experience for the following posts.

SENIOR PHYSICIST in a team serving the Glasgow Institute of Radiotherapeutics. The Institute's resources include four linear accelerators, neutron generators, computing facilities and a cell-culture laboratory. Special interests include fractionation, metabolic effects of radiation, computing techniques and cellular biology.

SENIOR ELECTRONIC ENGINEER/PHYSICIST in the bioengineering project division undertaking research and development work in cooperation with medical and scientific colleagues in many hospitals. In addition to making a personal contribution of original work the duties include the direction of other graduates and highly qualified technical staff.

Salary scale £2,769 per annum by 6 to £3,591 per annum.

Application forms and job descriptions may be obtained from the Regional Physicist, Western Regional Hospital Board, Department of Clinical Physics and Bio-Engineering, 11 West Graham Street, Glasgow G4 9LF. The last date for applications, Friday January 25, 1974.

(81)

UNIVERSITY OF LEICESTER

READER OR SENIOR LECTURER IN GENETICS

Applications are invited for the post of READER or SENIOR LECTURER in the Department of Genetics. Applicants should have experience in teaching medical students and an interest in human or medical genetics. The person appointed will be responsible for the development of these aspects of genetics in the department consequent upon the foundation of the new medical school, and will be expected to take part in the promotion of developmental medicine in the teaching hospitals. A medical qualification is therefore desirable but not essential.

Level of appointment and initial salary, dependent on qualifications and experience, within the scale £4,368 to £5,496 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by January 28. (74)

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

Graduate Teaching Assistantships

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc. and Ph.D. degrees in chemistry. Excellent research facilities are available in all areas of modern chemical science, ranging from bio-inorganic chemistry to chemical physics. Beginning stipends range from $4,350 to $4,550 per annum and depend on the qualifications and seniority of the graduate student. In addition, many special merit awards are made to those Graduate Teaching Assistants who show excellence in the performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned.

Professor C. A. McDowell,
Department of Chemistry,
University of British Columbia,
Vancouver, British Columbia,
Canada V6T 1W5. (X2)

L'UNIVERSITE DE MONTREAL

cherche
un

PROFESSEUR D'ECOLOGIE VEGETALE

Qualités requises: Ph.D. ou D.Sc. et expérience de recherche en écologie végétale, de préférence sur les plantes supérieures et avec aspects physiologiques ou génétiques plutôt que phytosociologiques. Possession de la langue française parlée et écrite.

Fonctions: Enseignement de la botanique et plus particulièrement de l'écologie végétale. Recherches. Direction d'étudiants à la maîtrise et au doctorat. Participation à la vie du département.

Titre et traitement: Professeur adjoint, agrégé ou titulaire; de $12,500 à $20,660 par année suivant les qualités du candidat.

Entrée en fonction: Aussitôt que possible.

Date de clôture de réception des candidatures: le 31 mars 1974.

Toute personne intéressée à poser sa candidature est invitée à écrire à:

Professeur Pierre Jolicoeur, Directeur
Département des Sciences biologiques
Université de Montréal
Case postale 6128
Montréal 101, Québec, Canada. (127)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

EXPERIMENTAL OFFICER

(Ref. EEP/10/3)

A temporary Experimental Officer is required in a joint laboratory of Electrical Engineering and Physics to assist in research on the physics of contact electrification.

Applicants, who should hold a degree or similar qualification, should be interested in carrying out experimental work in solid-state physics.

The appointment will be for 2 or 3 years at a salary within the scale £1,569 to £2,889 with F.S.S.U.

Requests for application form, quoting Ref. EEP/10/3, should be sent to: The Registrar, U.M.I.S.T., Sackville Street, Manchester M60 1QD.

Closing date for applications: February 28, 1974. (130)

CELLULAR AND MOLECULAR BIOLOGY

A senior position at the rank of Full or Associate Professor is available in the Department of Biology, York University, Toronto, tenable July 1, 1974. Preferred areas of research interest are: genetics and biochemistry of development, cellular and molecular genetics, neurobiology. Exceptional junior candidates may also be considered. Salary negotiable and commensurate with rank.

Send curriculum vitae, reprints and names of three referees to Professor J. D. Friesen, Department of Biology, York University, 4700 Keele Street, Downsview, Ontario M3J 1[illegible]3, Canada. (114)

MOUNT ALLISON UNIVERSITY

SACKVILLE, N. B., CANADA

The Department of Biology wishes to appoint an ECOLOGIST to its staff, for the academic year 1974–75, to replace a faculty member on sabbatical leave. The appointee will be responsible for two courses: a course on current environmental problems and the man-biosphere relationship, and a course on terrestrial flora and fauna. Opportunities for research. It is expected that the appointee will hold the Ph.D. degree, and have some experience. The appointment can be made at any academic rank, and salary will be commensurate with qualifications and experience.

Applications with curriculum vitae and names of three referees should be sent to Dr C. G. Paterson, Department of Biology, Mount Allison University, Sackville, N. B., Canada. (90)

THE UNIVERSITY OF BIRMINGHAM

INSTITUTE OF CHILD HEALTH

Applications are invited for the post of RESEARCH ASSOCIATE to assist in a 3-year research project to study the relationship between growth hormone, sulphation factor and sex hormones in disorders of growth and puberty in children. The successful applicant would work in the laboratories of the Institute of Child Health, University of Birmingham, under the direction of a Principal Grade Biochemist and Consultant Paediatrician.

Initial salary in the range: £1,569 to £1,785 plus F.S.S.U.

Applications giving details of age, qualifications and experience by January 19, 1974, to Dr. P. H. W. Rayner, Senior Lecturer in Paediatrics, Institute of Child Health, Francis Road, Birmingham B16 8ET. (146)

UNIVERSITY OF LONDON

CHAIR OF CELL BIOLOGY ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

The Senate invite applications for the above Chair. Initial salary to be agreed but not less than £5,625 a year plus £162 London Allowance.

Applications (10 copies) should be received not later than Friday, February 15, 1974, by the Academic Registrar (N), University of London, Senate House, WC1E 7HU, from whom further particulars should first be obtained. (86)

POSITION OPEN

HEAD—DEPARTMENT OF ANATOMY

Applications are invited for the position of head of the department of anatomy at Wayne State University School of Medicine. The position calls for a man or woman having either a Ph.D. or M.D. degree with a strong background in anatomy. Qualified candidates should manifest scholarship in research and teaching along with administrative capacity. The deadline for receipt of applications is April 5, 1974. Starting date and salary are open.

Send letters of inquiry, curriculum vitae, and names of three referees to Dr. Richard S. Berk, Department of Immunology and Microbiology, Wayne State University School of Medicine, Detroit, MI 48201. We are an equal opportunity employer. (132)

THE OPEN UNIVERSITY

Science Faculty

Technician Grade 4 in Chemistry

Applications are invited for the above post to be taken up as soon as possible. Duties include assistance with research within the discipline, the development of Summer School experiments, demonstrations related to the TV programmes and the home experiment kits. The opportunity also exists to use UV and IR spectrophotometers, gas-liquid chromatograph and a glass vacuum system.

Salary within the scale: £1,848 to £2,163 per annum.

Further particulars may be obtained from the Acting Personnel Manager (CT3), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL. Closing date: Friday, January 25, 1974. (138)

THE UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

Applications are invited for the post of DIRECTOR of the Welsh Plant Breeding Station, Aberystwyth. The appointment, which will take effect from October 1, 1974, is currently graded as Deputy Chief Scientific Officer in the Agricultural Research Service at a salary within the scale of £6,807 to £7,700 with an allowance of 4½ per cent to offset contributions to F.S.S.U.

The Director will also be a Professor of the University College of Wales, Aberystwyth.

Further particulars can be obtained from the Registrar, to whom applications should be sent by January 31, 1974, together with the names and addresses of three referees. (145)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CHEMISTRY

LECTURER IN ORGANIC CHEMISTRY

Applications are invited for an appointment as LECTURER IN ORGANIC CHEMISTRY. The salary scale for the lecturer grade ranges from £1,929 to £4,548 per annum, with F.S.S.U., and it is expected that the appointment will be made within the range £1,929 to £2,223.

Forms of application and further details, returnable not later than February 18, 1974, are obtainable from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Ref. No. 320. (144)

DEPARTMENT OF BIOLOGY QUEEN'S UNIVERSITY

KINGSTON, ONTARIO

Applications are invited for 3 positions in this department in the general areas (i) vertebrate biology, (ii) cell or developmental biology, and (iii) experimental plant science. Well qualified candidates in related fields may also be considered.

Appointments will be made at the rank of Assistant Professor to start July 1 or September 1, 1974, and will initially be for a period of 1 to 3 years. Successful candidates will be expected to teach comparative anatomy, or introductory cell biology, or plant science (as appropriate), and participate in the graduate and research programmes of the department.

Apply with curriculum vitae to Dr G. R. Wyatt, Head of the Department of Biology, Queen's University, Kingston K7L 3N6, Canada. (118)

TECHNICIAN AND JUNIOR TECHNICIAN required in Department of Clinical Pharmacology to assist in studies on the biochemical properties of cell membranes in relation to receptors for drugs and other biologically active compounds. HNC in Medical Laboratory Science or Applied Biology preferred and previous experience in protein or carbohydrate chemistry advantageous but not essential. Salary according to age, experience and qualifications within scale £708 to £1,395 plus £126 L.W. for Junior Technician and £1,440 to £1,845 plus £126 L.W. for Technician.—Apply, The Secretary, St. Mary's Hospital Medical School, Paddington W2 1PG quoting Ref. CLM 1. (113)

UNIVERSITY OF WINDSOR

DEPARTMENT OF PHYSICS

FACULTY APPOINTMENT IN RELATIVITY

It is hoped to make the appointment at the rank of Assistant Professor or Associate Professor, with duties to begin on July 1, 1974. Preference will be given to applicants with particular qualifications and interests in the theory of relativity and its applications. The successful candidate will be expected to engage in the teaching of undergraduate and postgraduate students, and to participate in the research activities of the Relativistic Group.

Further information may be obtained from Dr L. Krause, Head of the Department. (117)

UNIVERSITY OF GUELPH

DEPARTMENT OF CHEMISTRY

FACULTY POSITION

Applications are invited for a faculty position at the rank of professor, to begin September 1, 1974, to January 1, 1975. Candidates must have a Ph.D. degree in chemistry or biochemistry, a considerable record of research accomplishment in biochemistry or biophysical chemistry, and teaching experience in chemistry or biochemistry. Salary will depend on qualifications and experience. Duties include teaching, supervision of graduate research, and independent research.

Applicants should provide a full curriculum vitae and the names of three referees to A. K. Colter, Chairman, Department of Chemistry, University of Guelph, Guelph, Ontario N1G 2W1, Canada. (115)

UNIVERSITY OF CAMBRIDGE

RESEARCH ASSISTANT

Applications are invited for the position of Graduate Research Assistant from February 1 to July 30, 1974. The work will involve the application of operant techniques to the study of nest-building behaviour in canaries.

Applications including a brief curriculum vitae and the names of two referees should be sent to Dr Joan Stevenson-Hinde, Sub-Department of Animal Behaviour, Madingley, Cambridge CB3 8AA. (110)

ST. BARTHOLOMEW'S HOSPITAL

LONDON, E.C.1

PHYSICS DEPARTMENT

Applications are invited for a post of PRINCIPAL PHYSICIST in the Department of Radiation Physics. The main responsibility of the holder of the post will be to provide a comprehensive clinical physics service to provide the Department of Radiotherapy and to undertake research and developmental work on relevant topics.. Other duties include supervision on the Radiological Protection Service in the Hospital, and consultation on diagnostic X-ray apparatus. Some lecturing in M.Sc. courses and supervision of students reading for higher degrees will also be expected.

Applications, including curriculum vitae, and names of three referees, should be sent to the Personnel Department by January 22, 1974, quoting PT/3874/N. (111)

GUY'S HOSPITAL MEDICAL SCHOOL

Ergonomist or other graduate research assistant with an interest in Biometrics required as soon as possible to join a medical team studying the inter-relationships between work style and back pain. Further particulars and application forms may be obtained from the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT. Applications should be received by January 21, 1974. (168)

CENTRAL MIDDLESEX HOSPITAL

PARK ROYAL, LONDON NW10 7NS

SENIOR TECHNICIAN/TECHNICIAN required for department of Chemical Pathology. For further details and visit to department telephone Chief Technician, 01-965 5733, Ext. 551. (166)

MCMASTER UNIVERSITY

HAMILTON, ONTARIO, CANADA

DEPARTMENT OF APPLIED MATHEMATICS

Applications are invited for one or more appointments at Assistant Professor level, possibly higher rank. Areas: Appl. Math., O.R., or Comp. Sci. Ph.D. required, previous teaching experience desirable. Starting date: July 1, 1973. 1973/74 minimum salary level: Assistant Professor $12,000. Applicants to send curriculum vitae, details of research and teaching experience, list of publications, and names of 3 referees, to Dr. G. Field, Chairman, Applied Mathematics Department, McMaster University, Hamilton, Ontario, L8S4K1, from whom further details may be obtained. (151)

POSTDOCTORAL RESEARCH IN IMMUNOLOGY

A position is open for research on cell-mediated immunity in relation to cancer. Recent Ph.D. preferred.

Send curriculum vitae to: Dr. E. Sabbadini, Department of Immunology, University of Manitoba, 795 McDermot Avenue, Winnipeg, Manitoba, Canada R3E 0W3. (152)

THE KENNEDY INSTITUTE

IMMUNOLOGY DIVISION

RESEARCH TECHNICIAN required in the Laboratory of Immunochemistry for work on antibody affinity under the direction of Dr. M. Steward. Minimum qualifications Higher National Certificate or equivalent, preferably with experience of biochemical or immunological techniques. Written applications, naming two referees, to: the Laboratory Superintendent, The Kennedy Institute, Bute Gardens, Hammersmith, W6 7DW. (170)

TECHNICIAN required to assist with original biochemical and immunological research on cancer. Experience in a relevant subject is desirable but not essential. The successful candidate will be appointed on a salary scale of £1,440 to £2,292.—Apply enclosing a curriculum vitae and the names of two referees to: Dr G. Wiernik, Research Institute, Churchill Hospital, Headington, Oxford. (91)

SENIOR HARVARD CHAIR in the School of Public Health, the John Rock Professor of Population Sciences is to be filled by a scholar specialising in population. Harvard is an equal opportunity employer. To be considered please write Dr Howard H. Hiatt, Dean, Harvard School of Public Health, 55 Shattuck Street, Boston, Massachusetts 02115. (83)

ABSTRACTOR

A graduate in zoology is required for full-time abstracting work. A knowledge of a foreign language is an advantage. Please apply to Dr. E. S. Krudy, Information Retrieval Ltd., 1 Falconberg Court, London W1V 5FG. (169)

DEPARTMENT OF CHEMISTRY

UNIVERSITY OF LEICESTER

A TECHNICIAN (Grade 6) is required to take responsibility for the Inorganic, Organic and Physical Chemistry Teaching Laboratories. Salary £2,370 to £2,874 per annum.

Apply, giving full details of experience, qualifications and the names of two referees to Mr H. T. Whitt. (128)

BIO-MEDICAL GRADUATE

Major bio-medical publishing company requires recent graduate to assist the Marketing Director in the world-wide promotion and sale of scientific periodicals. Candidates must be prepared after training to travel. Offices in Central London. Initially send curriculum vitae with current address and telephone number to A. J. Woodcock, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (164)

LABORATORY TECHNICIAN GRADE 3 REquired to assist in the Electron Microscope Unit. "A" level or equivalent standard required. Experience desirable but not essential as full training given. Salary in range £1,650 by £54 to £1,920 per annum plus £175 per annum London Weighting. Five-day week. Five weeks (in total) annual leave. Letters only to Assistant Secretary (Establishment) (EMU/T), Queen Mary College, Mile End Road, London E1 4NS, stating age, experience and qualifications. (140)

SYMPOSIUM

SOCIETY OF CHEMICAL INDUSTRY

LONDON SECTION

A Symposium on CATALYSIS AND INHIBITION OF OXIDATION PROCESSES, arranged by Professor N. URI, will be held at THE CITY UNIVERSITY, St John Street, London EC1V 4PB, on Monday, March 4, 1974.

PROGRAMME: 9.15 a.m., Opening of the Symposium, Dr R. M. Evans, Chairman, London Section. 9.20 a.m. to 10.45 a.m., General Principles of Catalytic Oxidation, Dr. R. J. Sampson (I.C.I. Petrochemicals Division). 10.45 a.m. to 11.45 a.m., Catalytic Oxidation of Olefins on Metals and on Certain Metal Ketonides, Professor D. Bryce-Smith (Reading University). 11.45 a.m. to 12.45 p.m., Use of Noble Metals in Catalytic Oxidation, Dr G. J. K. Acres (Johnson Matthey Ltd). 12.45 p.m. to 2.00 p.m., Lunch. 2.00 p.m. to 3.00 p.m., Use of Antioxidants in the Food Industry, Mr K. G. Berger (J. Lyons and Co). 3.00 p.m. to 4.00 p.m., Thermal and Photochemical Oxidation of Polymers and its Prevention, Professor N. Uri (E.R.D.E. and The City University). 4.25 p.m. to 5.25 p.m., Catalysis and Inhibition of Paint Drying, Mr J. Turner (Hardman and Holden Ltd).

FEES: £3 for members of S.C.I. (inclusive of lunch); £5 for non-members (inclusive of lunch); £3 for the Symposium Dinner.

Registration forms can be obtained from Dr R. F. Greenwood, Hon. Secretary, London Section, Chemistry Department, The City University, St John Street, London EC1V 4PB. Telephone 01-253 4399. (175)

GRANTS & SCHOLARSHIPS

DUBLIN INSTITUTE FOR ADVANCED STUDIES

SCHOOL OF THEORETICAL PHYSICS

The Governing Board of the School of Theoretical Physics invites applications for RESEARCH SCHOLARSHIPS tenable in the School during the academic year 1974-75. A limited number of stipends will be available. These awards are normally made at postdoctoral level.

For further particulars and Forms of Application candidates should apply immediately to The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland. Completed applications should reach the Registrar on or before April 1, 1974. (161)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF MELBOURNE

SENIOR RESEARCH FELLOWSHIP

The University of Melbourne invites applications for a Senior Research Fellowship tenable for one year but renewable in special circumstances for a second. The Fellowship is intended for a scholar with considerable research experience, e.g., a senior member of academic staff who may be on sabbatical leave from his own university. The salary will be in the range of \$A12,268 and \$A15,187 and up to \$A1,000 may be paid towards the cost of transport.

Applications should be lodged with the Office of the Dean of Graduate Studies, University of Melbourne, Parkville, 3052, Victoria, Australia, by **February 28, 1974.**

Conditions for the Fellowship may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WO1H 0PF or from the undersigned.

R. A. CUMMING,
Secretary for Graduate Studies.
(100)

BRITISH MUSEUM (NATURAL HISTORY)

POSTGRADUATE RESEARCH STUDENTSHIPS 1974

Two studentships will be awarded, tenable for 3 years at the British Museum (Natural History) and commencing October 1974. Arrangements will be made with an appropriate university for higher degree registration and joint supervision of the research project.

The research areas for which applications are invited are as follows:

Department of Zoology

Biometric analysis of mammalian remains in relation to animal resources in Tudor England.

Department of Entomology

1. Cytotaxonomy of selected British Simuliidae (Black-flies, Diptera).
2. Biometric analysis of the Potato-Aphid species group.

There are good research facilities available including those for scanning and transmission electron microscopy, serology, biochemistry and biometrics.

Eligibility: Applicants to be British and normally resident in Great Britain, aged 27 or less and having a first or upper-second-class honours degree; students graduating in 1974 can be offered awards subject to their degree results reaching this level.

Students interested in applying should write to the Secretary (Postgraduate Studentships), British Museum (Natural History), Cromwell Road, London SW7 5BD, for application forms and conditions of the award. **Closing date for applications March 15, 1974.** (94)

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOWSHIP IN BIOLOGICAL SCIENCES

Applications are invited for the above post to work on the biochemistry of virus RNA replication. The post would be suitable for a biochemist with an interest in animal virology or a virologist with a good knowledge of biochemistry. Experience of working with nucleic acids or their polymerases would be an advantage. The appointment is for nineteen months commencing March 1, 1974. Salary in the range £1,929, £2,058, £2,223 per annum with F.S.S.U.

Further details and application forms may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, to whom completed forms should be returned by January 25, 1974, quoting Ref. No. 20/Q/73. (80)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENTS OF CHEMISTRY AND MICROBIOLOGY

A POSTDOCTORAL FELLOWSHIP

(Salary range: £1,929 to £2,223)

is available to work on the effect of metal/organic compounds on microbial growth reproduction and differentiation under the joint direction of Professor R. D. Gillard (Chemistry) and Professor D. E. Hughes (Microbiology).

Duties to commence as soon as possible. Closing date for applications is two weeks from the appearance of this advertisement.

Applications, together with the names and addresses of two referees, should be forwarded to the Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars will be available. Please quote reference 0973. (84)

European Molecular Biology Organization

(EMBO)

Short- and long-term fellowships in molecular biology

The European Molecular Biology Organization intends to award to scientists working in laboratories within the European area both short-term (from a few days to several weeks) and longer-term fellowships for collaborative research or advanced training in molecular biology.

The Short-term Fellowships are to support visits to other laboratories for the purpose of carrying out experiments with special techniques or of other forms of scientific collaboration or advanced training, and especially to support developments arising at short notice.

The Long-term Fellowships will usually be for a period of one year, but applications for renewal will be considered. They will be awarded upon individual application, at the "junior" level to promising young research workers who may then spend prolonged periods in other laboratories working under the guidance of leaders in the field of molecular biology. At the "senior" level, they may be awarded to enable established research workers to gain experience in new approaches and new problems. Upon application by European Institutions fellowships at the "senior" level may also be awarded to specialists who can assist in the initiation and development of research programmes in the sponsoring Institution. Such "sponsored" awards may be made to established workers at all stages of their career beyond the postdoctoral stage.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, 6900 Heidelberg 1, Postfach 2029 (Postfach 1022.40 after July 1, 1974), Germany.

Application for Short-term Fellowships may be made at any time and will be decided upon soon after receipt of the application. Applications for Long-term Fellowships should be made before February 1 for a decision by April 30 and before August 1 for a decision before October 31. Because the selection procedure involves an interview these deadlines for application should be respected.

(X4)

Ministry of Agriculture, Fisheries and Food

JOINT AGRICULTURAL DEVELOPMENT AND ADVISORY SERVICE/
AGRICULTURAL RESEARCH COUNCIL
TRANSIENT WATERLOGGING PROJECT

Junior Research Fellowship

1. The Agricultural Research Council has set up a project to study the effect on crop yields of transient waterlogging of soil during the growing season, which will assist in the design of field drainage systems. The project will be undertaken at the Council's Letcombe Laboratory, Wantage, Berks. and a Junior Research Fellow is required for a period of three years. Applications are invited from suitably qualified candidates.

DUTIES

2. The appointee will be a member of a research team investigating crop tolerances to transient waterlogging with a view to determining minimum drainage requirements and will have the opportunity of gaining experience of a wide range of plant physiological and physical methods for studying the performance of plant root systems in soils.

QUALIFICATIONS

3. A good honours degree in one of the Agricultural Sciences and at least 2 years postgraduate research experience.

REMUNERATION

4. The value of the Junior Research Fellowship is fixed for the duration at the time of appointment in the following range:

£1,789 to £2,335

Individual merit and experience will be taken into account by the Selection Board in recommending the value of the fellowship.

APPLICATION

5. Application forms may be obtained from Mr. J. Barnes, Personnel Division IIA Ministry of Agriculture, Fisheries and Food, Horseferry Road, London SW1. (01-834 8511 Ext. 6237.)

Closing date for completed applications February 1, 1974.

(143)

UNIVERSITY OF BRISTOL

The Department of Bacteriology has a vacancy for a two-year research studentship to investigate the fate of bacteria from sewage entering the Bristol Channel. The appointee will be expected to register for a higher degree and must therefore have a 1st or 2A honours degree. Studentship £825 per annum.

Applications, together with the names of two referees, should be sent to Professor M. H. Richmond, Department of Bacteriology, Medical School, University Walk, Bristol BS8 1TD.

(121)

UNIVERSITY OF SYDNEY

POSTDOCTORAL RESEARCH FELLOWSHIP
(PROTEIN CRYSTALLOGRAPHY)

Applications are invited for a post-doctoral Research Fellowship in the area of protein crystallography. The appointee will participate in a research project on the structure analysis of a metalloprotein, in collaboration with a group which includes crystallographers, biochemists, and co-ordination chemists. Experience in protein crystal structure analysis will be an advantage. Excellent instrumental and computational facilities exist.

Salary will be in the range $A7,270 to $A8,413 per annum. An allowance for travel to Australia will be paid. The appointment will be for one year in the first instance but may be renewed.

Applications, including details of experience and qualifications and names of two referees by February 8, 1974, to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information is available. Further details from Professor H. C. Freeman, Department of Inorganic Chemistry.

New from Prentice-Hall—an outstanding, in-depth analysis by two leading authorities—

MUSCLE PHYSIOLOGY

F. D. Carlson,

Johns Hopkins University

D. R. Wilkie,

University College, London

This informative text encompasses the entire field of muscle physiology based on biochemical, biophysical and physiological sources. Readily understandable, it offers students in pre-clinical medicine, biology, physiology, biophysics, and molecular biology a thorough grounding of the fundamental facts and concepts.

Through careful integration of epistomological and functional aspects, this valuable text presents the functional processes of muscle for comparison and contrast. Complete coverage of the initiation, control, and energy conversion process as they are presently thought to occur in the single muscle fiber.

Fast scan Far IR Spectroscopy

Fourier spectrophotometry has become established as the most practical method of obtaining information in the far infrared region of the spectrum where serious experimental difficulties exist for normal dispersive spectrophotometers due to the lack of intense radiation sources and sufficiently sensitive detectors for this characteristically low energy region.

The new IR-720, a complete far infrared spectrophotometer consisting of a Michelson interferometer, multi sample reflectance and transmittance unit with multi position filter holder and 3 m[illegible]ond window Golay det[illegible]The electronics unit is a single, ergonomically designed, bench mounted unit complete with digital readout of interferogram level and spectral plotter.

The IR-720 provides far infrared spectra with the ease and convenience usually associated with routine infrared spectrophotometers, a 3 wavenumber resolution spectrum over the range 500 – 20 wavenumbers being produced in about 4 minutes on the integral spectral plotter.

Using an optional tape punch it is possible to obtain interferometric data to achieve the limiting resolution of the Michelson interferometer of 0·1 wavenumbers. By simultaneously using the spectral plotter of the IR-720 over the central portion of the interferogram, moderate resolution spectra can be plotted directly to check the operating conditions and sampling for a high resolution tape prior to processing.

To take full advantage of the fast recording times, multi sample handling facilities are provided enabling up to 5 liquid or solid samples to be accommodated in the sample unit, each can be switched into the beam without releasing the sample compartment vacuum.

With this capability of multi sampling, simple operation and fast scanning the IR-720 provides the ease of accessibility to the far infrared region that already exists in the higher energy regions of the electromagnetic spectrum.

THE MOLECULAR BIOLOGY OF CANCER

edited by HARRIS BUSCH

Featuring the work of leading specialists in many phases of cancer research, this volume sums up recent progress in characterizing cancer cells and elucidating their fundamental properties. It provides in-depth discussions of the nuclei of cancer cells and describes the role of the nuclear constituents—including chromosomes, DNA, high and low molecular weight RNA, and nuclear proteins—in the oncogenic process. It also covers currently important aspects of carcinogenesis, phenotypic variants of cancer, and concepts relating metabolic characteristics with the development of neoplastic disease. In addition to offering a detailed and far-reaching evaluation of the current status of progress in cancer research, the book also points out the future directions for the extensive effort still needed to solve the cancer problem.

New York and London
111 FIFTH AVENUE, N. Y. 10003

THE ANTIGENS

Volume 1

edited by MICHAEL SELA

This is the first volume of a major work that will constitute a comprehensive treatise of modern immunochemistry. It deals specifically with antigens and the molecular aspects of immunology, discusses nucleic acids and enzymes as antigens, and devotes authoritative chapters to immunoglobulins. Topics discussed include: nucleic acid antigens; immunochemistry of enzymes; structure of immunoglobulins; immunoglobulin allotypes; the evolution of proteins; phylogeny of immunoglobulins; and chemistry and biology of immunoglobulin E.

1973, 590 pp., $35.00/Subscription price: $29.50

THE HERPESVIRUSES

edited by ALBERT S. KAPLAN

This volume brings together in a single source all currently available information on the cellular and molecular interactions of herpesviruses and their hosts—with emphasis on replication and the association of herpesviruses with certain types of cancer. The book is divided into two parts covering both basic and clinical aspects of herpesviruses. The first part deals with the classification, morphology, physiochemical properties, replication, and immunological relationships of herpesviruses—and includes chapters on interference and interferon, as well as persistent and latent infections. The second part covers specific diseases of man and animals and discusses the essential clinical features, pathogenesis, immunity, and epidemiology of each virus-linked disease—with four chapters devoted specifically to those herpesviruses linked with carcinogenesis. The last two chapters discuss molecular and clinical aspects of antiviral chemotherapy.

1973, 768 pp., $31.00

Second Edition

BIOCHEMICAL ENGINEERING

by SHUICHI AIBA, ARTHUR E. HUMPHREY and NANCY F. MILLIS

Here is the second edition of a book that has provided—since the publication of its first edition in 1965—an essential bridge between the disciplines of biology and chemical engineering in the fermentation industry. Like the first edition, the second edition of BIOCHEMICAL ENGINEERING presents an engineering approach to the microbial world which will satisfy the needs of both disciplines. The present volume has extensive revisions of the sections on biological mechanisms of control, kinetics, scale-up and the methods for the measurement and control of fermentation parameters, with special emphasis on the management and control of oxygen transfer. The new chapters deal with the recovery of cells, their disruption and fractionation, and with the extraction and immobilization of macromolecules. In addition, summaries have been added at the end of each chapter.

1973, 425 pp., $28.50

BASIC SLEEP MECHANISMS

edited by OLGA J. PETRE-QUADENS and JOHN D. SCHLAG

BASIC SLEEP MECHANISMS provides a comprehensive review and discussion of recent research and literature on sleep. It is the revised and edited version of the papers presented at a conference held at Bruges, Belgium, on June 24-30, 1971—a conference at which physiologists, biochemists, anatomists, pharmacologists, and clinicians reported on recent progress in their respective fields. Each contributor discusses the problems encountered in his own domain in a way that makes them accessible to specialists in other fields. Topics discussed include: neurophysiological mechanisms of sleep; neurochemical mechanisms of sleep; adult human sleep states; and developmental aspects of sleep patterns.

1974, 342 pp., $23.50, £11.00

PRIMATE LOCOMOTION

edited by FARISH A. JENKINS, Jr.

This book presents recent research concerning locomotor adaptations in primates. The papers discuss both the fossil evidence bearing on evolutionary matters and the results of recent field and laboratory studies on prosimian and higher primates. Rather than attempting an exhaustive account of the whole field, they cover selected topics in depth—including classical biomechanics, anatomy, paleontology, and ethology. Of particular interest are chapters based on cineradiographic and electromyographic data—relatively new techniques in primate locomotion studies.

1973, 408 pp., $34.00, £16.00

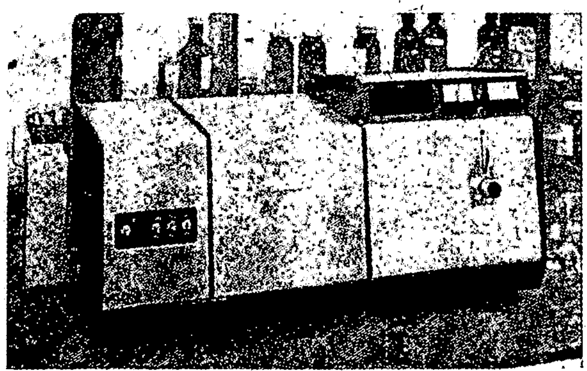
Precision Instruments

Polarimeter Model P.70



A long time has been spent developing this photo-electric polarimeter, and we are now satisfied that it will please the most discerning user. It has the accuracy of rotational measurement that can only be achieved from a ruled circle, plus independent magneto-optical compensation for recording or digital presentation, should it be required.

There are four models from which to choose, all virtually identical in external appearance, but with internal variations to provide the particular facilities that you require.

We now have capacity for aluminising certain types of mirrors, at short notice.

Full details from the manufacturers:

The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at ½p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects or "burn out".

Assembly No retort stands or clamps are required. The 2½-in. diameter ball joint gives a strainless set-up. Outlet ca on boiler for quick periodical drain-off of sediment. The sti may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

Manufacturers of Silica & Scientific Glass Apparatus Telephone Cambridge (OCA3) 63045/61768

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système Internationale. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Because of the imposition of a three-day working week in Britain, *Nature* is being printed in the United States by the William Byrd Press in Richmond, Virginia, for the duration of the emergency. This issue is the first to be printed in the United States, and it has been made up of material set partly in England and partly in the United States. Every effort is being made to ensure that subscribers receive their copies at the normal time.

The London office continues to be open five days a week, and manuscripts are being handled there normally. Subscriptions are also still being dealt with at the Subscriptions Department in Basingstoke, England.

We regret that *Nature* has again been reduced to 64 pages this week. Next week's issue will, however, be up to 96 pages and we hope to publish that number of pages for the duration of the power crisis.

Subscriptions to NATURE

Subscription Department, Macmillan Journals Ltd, Brunel Road, Basingstoke,
Hampshire RG21 2XS.

Please send me 52 issues of NATURE starting with the issue dated.............

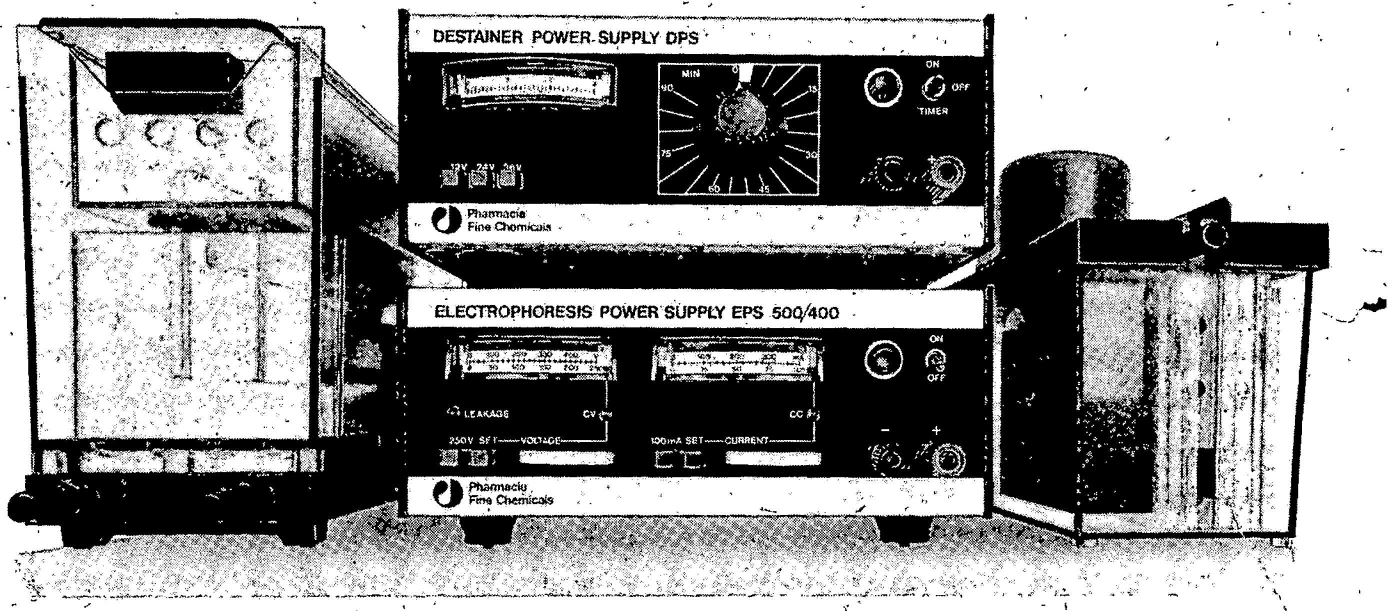
This is a new P.A.G.E.



Pharmacia Gel Electrophoresis System

for polyacrylamide gradient electrophoresis and other P.A.G.E. techniques

The complete system
Full capabilities for the new pore gradient electrophoresis technique, two-dimensional studies, gel rod electrophoresis.

Polyacrylamide gradient gels PAA 4/30
Convenient ready-to-use gradient gel slabs give extreme resolution over the whole range 50,000–2 million MW. Self-limiting migration concentrates the zones after separation by molecular size.

Gel electrophoresis apparatus GE-4
4 gel slabs, 12 samples on each, or 16 gel rod capacity. Robust moulded construction with built-in cooling system. Full range of accessories for all applications.

Electrophoresis power supply EPS 500/400
Compact, all solid state. 0–400 mA constant current, 0–500 V constant voltage with automatic cross-over. Maximum effect 60 W. Full personnel and instrument protection. Available 1974.

Gel destainer GD-4
Electrophoretic or diffusion destaining of slabs or rods in a single operation. Twin cells. Active dye removal and solvent circulation. Results can be inspected at any time.

Destainer power supply DPS
Compact, reliable, all solid state. Push-button selected constant voltages 12, 24, or 36 V. Timer controls electrophoretic destaining up to 90 minutes.

Research and energy independence

DURING the past year, the Nixon Administration has done a rather spectacular U-turn in its public statements on energy research and development. Back in April 1973, when President Nixon was still referring to the looming energy shortages as a challenge rather than a crisis, he said "it is foolish and self-defeating to allocate funds (to energy research and development) more rapidly than they can be effectively spent". But in June he found himself not only promising to spend an extra $100 million this year, but also announcing that this would be followed by a five-year energy research and development programme which will begin in 1975 and which will eventually soak up $10,000 million in federal funds. Finally, in November, the President was claiming that this technological effort, coupled with conservation measures, could win independence for the United States from foreign suppliers of oil by 1980.

Welcome as this late espousal of the technological answer may be—particularly for those directly engaged in such research and development—there are nevertheless, strong doubts about whether such a research and development programme will be sufficient to ensure independence. And there are also questions—based as much on the structure of the federal government itself as on the Administration's poor track record in supporting science and technology—about the endurance of the commitment to energy research.

The Administration's research and development effort is likely to follow a set of proposals drawn up by the Chairman of the Atomic Energy Commission at President Nixon's request, and delivered to the White House in December (see *Nature*, **246**, 370; 1973). The proposals, which conformed to President Nixon's suggested ceiling of $10,000 million for a five-year programme, call for massive concentration on short term goals, such as more effective use of coal and energy conservation, and they also call for almost half the money to be spent on nuclear research and development.

The first thing to be said is that Presidential claims notwithstanding, the suggestion that the United States will be self sufficient in energy by 1980 is nonsense. Even with the $10,000 million programme, the AEC report suggests that the United States will in fact be importing more oil in 1980 than at present (5.9 million barrels, compared with 5.1 million in 1972). 1985 is the earliest date by which independence can be achieved, the report says, and even that prediction is based on some dubious assumptions.

For one thing, the Administration's plan tacitly assumes that once the federal government has done the research and development and proven the feasibility of energy technologies, private industry will quickly step in and provide the capital necessary to exploit it. Certainly, the AEC's plan calls for some joint industry–government collaboration in setting up pilot plants, but even the Chairman of the Atomic Energy Commission, Dr Dixie Lee Ray, reckoned at a meeting of the President's Energy R&D Advisory Council in December that it will cost as much as $50,000 million to exploit the fruits of the research and development programme.

A better approach to buying independence for the United States is contained in a bill sponsored chiefly by Senator Henry M. Jackson, which was passed by the Senate at about the same time as the AEC report was sent to the White House. Not only does that bill provide much more money—Jackson reckons as much as $15,000 million on all energy research and development would be spent between 1975 and 1979 if his bill is adopted—but it also contains an important provision authorising the establishment of joint government–industry development programmes. These would provide federal funds directly for the construction of demonstration plants to exploit new energy technologies and would provide a measure of government control over their operation. That bill is now awaiting action in the House of Representatives, where it demands careful consideration. But even if it survives the Congressional circuit, there is still no guarantee that the money would be spent, for it would then have to go through the appropriations route, and the Administration would also have to be persuaded to spend the money.

100 years ago

IS England rapidly losing that commercial and manufacturing supremacy which she has held before all the world for generations past? Is she going the way of Venice, of Florence, of Holland? If so, is it because she feels blindly secure that "what hath been, will be," neglecting the means on which success in commerce and manufactures in these days depends—means which are being so industriously used by rival nations, that they are rapidly shooting ahead of England on England's own ground?

international news

Kohoutek makes a good night out

John Hall

ITS complex molecules apart, there is no doubt that the biggest let-down of the astronomical year was the arrival of the hapless Dr Kohoutek's comet. After nine months of speculation and counter speculation about the size and brightness of this spectacle it is now possible to make a single dogmatic assertion on the subject without fear of contradiction: that distance lent enchantment to the eye. The thing is not going to bowl over anybody on account of its splendour, and the complex molecules cannot be detected with binoculars.

Turning a blind eye to the dim reality of the phenomenon, at least two British companies had the enterprise to cash in on Kohoutek. Kohoutek Ltd settled for comet 'T' shirts and a million shares at a penny a go, and Transolar Travel plumped for an observation flight, price £12 to £24 a head, which pulled in 140 enthusiasts, culled largely from the ranks of amateur astronomy societies. The media were there to observe the observers and, curiously for an event which was to be enjoyed at a distance of 90 million miles, clutches of spotters milled about with portable tape recorders and instamatic cameras topped with flash cubes which could scarcely have thrown much light on the subject. The British astronomer Mr Patrick Moore was clearly visible to the naked eye.

The tone of the expedition was set at a preliminary lecture, at which a director of Transolar projected an artist's impression of a nineteenth century comet, about as bright as a full moon and stretching half across the sky, which he confessed to be much the sort of show he expected from Kohoutek. This was greeted by polite laughter from the spotters who throughout the lecture insisted on photographing the lecturer, the slides, each other, and such aeroplanes as passed within range.

Once above the Gatwick clouds in a couple of BAC 1-11s, an excited babbling broke out as Venus and Jupiter hove into view, and a gentleman from the BBC paced the gangway soliloquising about the agitation. Then from the flight deck an announcement was made that, at 33,000 feet, the comet was no longer obscured by cloud, and it was all going to be worthwhile. Patrick Moore raised his voice above all others to issue directions for identifying the target ("left from Venus to Jupiter, then up a bit") and was heavily photographed for his pains.

Then, sure enough, we were able to see a distinct sort of smudge, with a tail extending five degrees maybe, representing perhaps six and a half million miles, and of magnitude three and a half, possibly. Certainly it was a distinct sort of smudge. More plainly, it was possible to make out the street lighting of Wales, Wallasey and the shape of the Mersey estuary, then the Isle of Man, Manchester and, more controversially, Leeds.

The astronomers passed among each other cassette recorders, making essays in historical audio verité. "Have you seen the comet?" "Yes, I've seen the comet. It has a tail extending five degrees maybe, representing perhaps six and a half million . . ." and so on. Finally, since there was only one window to every two observers, those who did not have the good fortune to be twisting their necks and spines to crane after the comet, insisted on paying their respects to the captain, since a better view could be had from the flight deck. A visiting rota had to be arranged when the astronomers, firing their flash cubes as they went, were thought to be harassing the pilot. "It's all very well, but we just cannot have people sitting on the captain's shoulders", the Transolar man remonstrated.

Patrick Moore initiated a round of rousing applause for the organisers, who had put on the entire junket with nothing to gain but hard cash, and the only note of concern was voiced when we passed, on the Lancashire coast, a bright flame of petrochemical waste which, I commented, looked remarkably like the exhaust of a SAM-7 missile.

Nuclear safety

Colin Norman, Washington

THE longstanding and bitter dispute about the safety of American light water reactors is about to boil up again in the United States. Next week, the Joint Committee on Atomic Energy is planning to hold three days of public hearings which will put the spotlight on perhaps the most contentious nuclear safety issue: the emergency cooling system which is supposed to flood the reactor core with water if an accident suddenly robs the reactor of coolant. Arguments about whether or not this piece of hardware would actually work in an emergency have been batted back and forth between the Atomic Energy Commission and its critics for the past two or three years. Since the British Government may soon put in an order for American reactors, the matter is of more than parochial interest.

Next week's hearings, which will take place on January 22–24, will be concerned chiefly with a number of regulations issued by the AEC at the end of December. Based on a marathon public inquiry into the functioning of the emergency core cooling system (ECCS), held by the AEC over a four-month period last year, the regulations will reduce the peak operating temperature of light water reactors by 100°F, and put limits on the amount of oxidation permitted in the fuel cladding.

According to officials of the Atomic Energy Commission, the regulations will reduce the power output from some reactors, and provide an adequate margin of safety in the (unlikely) event of loss of coolant. According to the critics, however, they do no such thing, since the regulations are merely cosmetic changes designed mostly for public relations purposes.

The hearings will also take place against a backdrop of persistent rumours of palace revolts and power struggles among top AEC officials. According to some accounts, open warfare has broken out between Dr Dixie Lee Ray, the Chairman of the AEC, and some of the other commissioners. A number of key officials have resigned from the agency in the past few months, including Mr Milton Shaw, director of the Division of Reactor Technology, Mr Robert E. Hollingsworth, the AEC's General Manager, and Alvin M. Weinberg, Director of the Oak Ridge Laboratory. Moreover, James T. Ramey, a former general counsel of the Joint Committee on Atomic Energy, was reappointed to the Commission last year after his term of office expired. Since Ramey provided a link between the AEC and its Congressional watchdog, his loss has stirred up considerable animosity between Dr Ray and some committee members.

Scientists are playing their part in power saving

John Hall

IN Britain the arrival of the three-day working week, complete with regulations restricting the use of power, raises the spectre of an earlier age of science. Might one expect, without undue romanticism, to be conducting enquiries by the glow of a tallow candle? The speculation, as it happens, turns out to be as inaccurate as it is morbid. By and large, research goes ahead under neon lights, albeit fewer of them, and with power supplies reduced in some cases 60% of normal and in others not at

The Statutory Order restricting the use of electricity offers three channels of escape (at least) which ensure the survival of research programmes whose existence depends on supplies of power. In the first place, work which is taking place at a university is in the clear because of the exemption from cuts allowed to places of education. A further clause in the order allows the operation of apparatus "which has been continuously in use for purposes of research until such time as the operation of the said apparatus can be discontinued without causing loss or damage"—a flexible-looking provision, since the order does not actually specify that the loss should be of materials rather than of information. And additionally, the regular supply of power is allowed for the operation of any computer "and any other equipment necessary for the proper functioning thereof". As a last resort a laboratory can make a special plea to regional officers of the Department of Trade and Industry, who have been instructed to avoid "rigid attitudes" in dealing with such applications.

At Jodrell Bank, in spite of a power reduction of 75%, the radio telescopes are still functioning twenty-four hours a day for seven days a week. In fact, says Professor Sir Bernard Lovell, the telescopes use less power than the cooker in the station's canteen. The total load for the entire establishment at present is only 35 kW and even if the regulations were changed in the event of a worsening power situation, Jodrell Bank's own generator could fill the gap for several weeks. The Appleton Laboratory, formerly the Radio and Space Research Station, at Slough is working a five-day week with only three days of power and has had to delay work on certain projects.

University College, London, which hopes to take its electricity for the full five days, but at a voluntarily reduced level of 60% of normal consumption, also has certain difficulties. As it happens, the Faculty of Medical Sciences has no animal experiments in train and since its other projects were part of teaching programmes, none of its work has been affected. The Department of Chemical Engineering, with a pilot plant which attempts to translate laboratory biochemistry into industrial process design, is, however, a heavy user of power. Large scale fermentation and isolation runs, carried out under industrial conditions, can use motor power amounting to 80 horse power.

Dr Peter Dunnill says the department can scarcely afford to have its £0.25 million worth of equipment standing idle but at the same time it is not really feasible to do biological research on a three-day week or at reduced power. Rather, the department will try to take its 60% of power at the normal rate for, say, one full week in every four.

The Royal Aircraft Establishment at Farnborough, reduced to 65% consumption, spread over five days a week, has elected, stoically, to "make do and mend". Computer work and continous process research is unaffected but testing programmes, including work for Concorde, has to be done "as and when we can manage it", said a spokesman. The nearby National Gas Turbine Establishment is working on the same basis.

The Atomic Energy Authority's research establishments at Culham and Harwell are surviving by using 65% of their November daily average requirement, as are the Dounreay Fast Reactor and the Winfrith Steam Generating Heavy Water Reactor—in spite of the fact that they generate 114 MW between them. Apparently it is considered unethical to plug in your lighting and heating at source.

Naples at the crossroads

THERE is great international interest in the establishment of new conditions at the Naples Zoological Station. The station fulfils for marine biology (along with a number of other stations such as Monaco, Plymouth and Woods Hole) similar functions to those that large accelerators do for nuclear physics. In addition to having a staff of its own, the station is capable of housing large numbers of international visitors. It is not alone among Italian scientific institutions in having recently fallen on hard times as a result of dissatisfaction with the administration among its resident workers.

The Italian government has reacted to discontent within the station by installing a Commissario whilst the administration was overhauled. A new set of statutes has been provided and the financial basis for the station is much sounder. Italy will provide about £400,000 annually and any country which contributes more than £40,000 annually will be entitled to a seat on the new Administrative Council. It is hoped that Britain will have a seat.

Prospects are much brighter for a settled future but the remaining question is whether the science will be stimulating. This hangs on two issues—who will be the new director and what sort of programmes will he institute? The permanent staff have gone to unusual lengths to ensure that the community is well informed of the needs of the station; a recent advertisement in *Nature* invited suggestions for the development of the institution and by inference nominations for the directorship. It is important at this juncture that, even though the station is understaffed, the decision not be made in a hurry—certainly not until the council has had time to feel its feet.

PSAC reports from the grave

Colin Norman, Washington

THE President's Science Advisory Committee (PSAC) has posthumously complained about the federal government's methods of regulating public exposure to chemicals in the United States. It has also added its ghostly voice to the chorus of opposition to one of the most controversial, and certainly the most effective, pieces of consumer legislation on the lawbooks—the so-called Delaney Amendment which seeks to ban the addition to food of any substance which has been found to cause cancer in animals.

Although PSAC was a victim of President Nixon's post-election massacre of the science advisory apparatus in the United States (the massacre which scrapped the Office of Science and Technology and banished scientists from the White House), its reports continue to surface in Washington as reminders of a past age in science policy making. This latest PSAC report (*Chemicals and Health*, US Government Printing Office, $2.75), was released last week by Dr H. Guyford Stever, Director of the National Science Foundation, and inheritor of most of the responsibilities which were assigned to the Office of Science and Technology. Stever described the report last week as a "broad, yet intensive, examination of the processes of Federal regulation of chemicals . . . performed in the name of health".

Prepared by a committee which met under the chairmanship of Dr John W. Tukey, Professor of Statistics at Princeton, the report argues for more flexibility in regulatory decision-making: in other words, for risks and benefits to be properly weighed before a chemical is banned or restricted. The committee also argues for more public disclosure of the principles behind regulatory decisions, for public discussion of issues as they arise, and for independent advisory committees to share the burden of regulation with government administrators. Like every other committee which has reported on the matter (and there have been several over the past decade), the PSAC committee also calls for more research into the health effects of environmental chemicals. In particular, it calls for a greater role in environmental research to be assigned to the National Institute of Environmental Health Sciences.

The committee reckons that one of its most important recommendations is that the Administrator of the Food and Drug Administration and the head of the Environmental Protection Agency should each have an advisory board to assist in major regulatory decisions. Such boards would consist of two classes of members: some would be appointed by the administrator from a list suggested by the National Academy of Sciences, and the rest would be drawn from the general public and appointed by the President. The idea would be for the boards to prepare reports and analyses at the administrator's request, and they would also be able to produce reports on their own initiative. Such an arrangement would be analogous in some respects to the Committee on the Safety of Drugs in the United Kingdom, except for the fact that the boards' reports would be made public—a far cry from the obsessive secrecy that surrounds the work of the British committee.

The PSAC report also comes up with the usual recommendations for increasing public participation in, and knowledge of, regulatory issues and decisions. It also makes the obvious—though frequently overlooked—point that the most widespread and damaging effects of exposure to chemicals come from the consumption of alcohol, tobacco and drugs. Programmes designed to protect public health should thus be directed chiefly at reducing consumption of those chemicals, the committee argues.

A more controversial part of the report is concerned with the Delaney Amendment. Although Dr Tukey said last week that the committee does not specifically disapprove of the Delaney Amendment, it is clear that the amendment is not exactly regarded as the epitome of good regulatory policy. What the committee chiefly objects to is the inflexibility that the clause imposes on the administrator of the Food and Drug Agency.

The amendment, which takes its name from John Delaney, a New York Congressman who is noted for little else, imposes an absolute ban on adding any chemical to food if it has been found to be carcinogenic to animals. The clause has always irked many food manufacturers, because it has led to the banning of chemicals on the basis of what they consider to be unrealistic tests. On the other hand, many cancer scientists have supported the clause because they argue that it should be government policy to reduce public exposure to carcinogens as much as possible. The PSAC committee adopts the position that the Administrator of FDA should have the ability to set safe levels of chemicals in food, on the basis of dose-response studies.

Publication of the report is timely, not only because some of the fiercest and most bitter battles between the federal government and the public continue to take place over the regulation of food additives, drugs and other chemicals in the environment, but also because the energy crisis is forcing the government to backtrack on environmental laws which are designed to protect people against harmful pollutants. Moreover, some trade unions in the United States are taking an increasingly keen interest in the exposure of workers to chemicals in the workplace. The Chemical and Atomic Workers Union, for example, recently held a long strike against the Shell Oil Company over working conditions, in which questions of exposure of workers to carcinogenic chemicals played a large part. Such disputes are clearly going to increase.

Soyuz-13

From our Soviet Correspondent

THE programme of the Soyuz-13 flight (December 18-26, 1973) seems to have been a multipurpose one, combining routine tests of the hardware, astrophysical and geophysical observations, and preparations for possible long term space flights in the future.

The emphasis given to further checks of the on-board systems, to new methods of manual and automatic control, and to autonomic navigation systems, seems at least partly aimed at maintaining the confidence of the United States participants in the forthcoming Soyuz-Apollo linkups. Indeed, one new navigation project involving observations and photographs of luminous effects before sunrise and after sunset, beyond the line of the horizon, can only be relevant for such orbital missions.

The medical checks, which include the new Levkaya apparatus to monitor cerebral circulation during weightlessness, in conditions of rest, and also after graduated exercise with a special expander with a pull of 30 kg at a rate of thirty times a minute, may also be directed in the first instance towards the joint project, although such data will obviously be of wide application in space medicine.

Similarly, for home consumption (for undercurrents of discontent at the cost of the Soviet space programme still emerge from time to time, mainly in the form of black humour), considerable press coverage has been given to the spectroscopic investigations of earth resources and pollution—now dignified by the name "cosmic ecology". Although this is one of the routine tasks of the Kosmos satellites, it is difficult to see the cost effectiveness of using a manned station for the purpose.

The most interesting feature, however, is that this short term flight has taken over two projects first envisa for the Salyut station, one astrophys and one biological. The Orion II telesc (an improved version of the Orion carried by Salyut) was used to carry out extensive ultraviolet spectroscopy of the Sun and stars. The new system includes a wide-field meniscus telescope capable of ultraviolet photography of stars down to magnitude 9.5 or 10.

The other experiment taken over from Salyut is the Oasis enclosed environment recycling system. Oasis originally contained higher plants such as flax and Peking cabbage. The new version, Oasis II, is a microorganism system which consists of two interconnected cylinders. The first cylinder contains bacteria which feed on hydrogen produced by electrolysis, whereas the oth[illegible] contains bacteria which break down urea, absorbing oxygen generated in the first cylinder and liberating carbon dioxide which is then used by the bacteria in the first cylinder. Although only a small scale version has been developed, the Oasis system is considered significant in the development of recycling systems for long duration space flight.

Energy largesse

The Administration's budget, which will be unveiled later this month, will contain some $1,570 million for energy research and development in the United States, according to Roy L. Ash, Director of the Office of Management and Budget. In an interview with a wire service reporter, Ash said that the Administration has accepted the spending proposals for the 1974–75 financial year contained in the energy research and development plan drawn up last month by the Chairman of the Atomic Energy Commission. The energy research budget next year will thus be some $700 million above the budget for this year. It will be interesting to see where the money comes from.

news and views

Geomagnetism and climatic change

THERE is a remarkable similarity between the pattern of the rth's magnetic field over the northern hemisphere, as disayed by the isopleths of magnetic intensity, and the mean ight contours of the surfaces of constant atmospheric pressure which define the shape of the circumpolar vortex of (broadly) westerly upper winds which prevail through most of the depth of the troposphere and lower stratosphere. Both patterns have an elongated, dumb-bell-like or bipolar form, at least when averages over a number of years are considered. In both cases, one end of the long axis is in the general region of the Canadian Arctic Archipelago, where the magnetic pole lies, and the other end is over northeast Siberia. In spite of its striking nature, this near-parallelism has received no more than passing notice in the literature of science. In an article on page 131 of this issue of *Nature*, King, of the Appleton Laboratory, Slough directs attention to the matter and adduces a number of other associations between the Earth's magnetic field and the atmospheric circulation and climate. These associations call for serious discussion and investigation, as they may indicate that the parallelism has a physical explanation, possibly of predictive value, in connection with long-term trends in climate.

Among the additional associations claimed by King perhaps the most impressive is just that the distinctive form of the isopleths of constant magnetic intensity over the southern hemisphere, much more nearly circular than in the north but eccentric in relation to the geographical pole with the pattern centred in the Indian Ocean sector, again broadly parallels the prevailing flow of the atmosphere (which has only been established by observation in recent years, roughly since the International Geophysical Year).

Meteorologists have been shy—perhaps understandably shy—about suggestions of a linkage, let alone control (as mentioned by King) of the flow of the atmosphere by the magnetic field, that is, ultimately by the flow in the Earth's molten core. But both phenomena could be registering parallel responses to some other aspect of the physical environment. The reluctance of meteorologists to consider these things doubtless has something to do with the fact that the atmosphere's dynamics and thermodynamics have long been explained adequately for most purposes (but perhaps not for the understanding of all long-term changes affecting climate) in terms of the major items of the energy budget at the Earth's surface and within the atmosphere, together with the effects of friction and distortion of the atmospheric flow by the greatest mountain barriers. Recent years have seen an impressive development of skill in forward calculation of the state of the atmosphere, based on these premises, using the capacity of the giant computers in the service of numerical methods of weather forecasting over one to five days ahead. It is natural that those who have been most closely involved in that particular advance of science should be a little reluctant to admit the need for other considerations in connection with long-term climatic development and changes—for example, the slow cumulative effects of extraneous influences, terrestrial and extra-terrestrial, and their possible trigger effects—and, perhaps, the appropriateness of quite other methods. It is far from clear, however, that the models used in numerical daily weather forecasting or any climatic models so far in sight will bring any advance at all in the capacity of scientists to forecast the weather a month or more ahead or to meet the demand for prediction of the climatic trend over years and decades ahead; though models can throw light on probable side effects of human activity (for example, increasing the carbon dioxide content of the atmosphere) which may modify the climate of the Earth.

King presents some further riddles in his article, in which a parallelism appears between the long-term displacement of the non-dipole element of the Earth's magnetic field and the behaviour of the atmospheric circulation over the northern hemisphere and its climatic effects suggest parallel histories over recent decades and centuries. Several of these apparent associations may turn out to be of only passing duration, and hence illusory, or they may be no better than loose and qualitative; but the facts will never be known unless they are investigated with the fullest assembly of long-term data that can be marshalled to the task. There is a clear, and urgent, need to identify and understand the physical processes that are involved in climatic changes—a need stressed, even before the current energy crisis, by the upsets to the international economy during the past 5 to 15 years by the long-continued, and increasing, drought in parts of Africa and several individual years of harvest failure over wide areas in India, China and the Soviet grainlands in central Asia.

Among the variables that have to be brought into the consideration of how climate varies, solar disturbance and minute, but directed, inputs of energy in high geomagnetic latitudes are often suggested. The ionosphere is well known to be affected by solar activity. Any responses in the lower atmosphere or, through the agency of geomagnetic disturbances, in the Earth's molten core are likely to differ with the time-scale of the external trigger operation; but they may show some common features and they are perhaps both likely to be more important in the case of long-lasting changes, however small in origin. One noticeable difference may already have been observed, which should warn meteorologists against expecting too close, or too complete, a paralellism: there is no suggestion so far that the geomagnetic field has registered a three-pole field over the northern hemisphere like that which has often appeared in the northern hemisphere atmosphere during the past 13 years (the third pole being near Novaya Zemlya.) Surely, however, no such strong hints of association as King points to should be left uninvestigated, especially when better knowledge of the processes of climate and climatic change is urgently needed. Another possibility is that such investigations may throw some light on the probable evolution of the flow in the Earth's molten core.

H. H. L.

Search for catecholamine receptors

Considerable progress has been made recently in the identification of membrane-bound receptor structures for polypeptide hormones such as insulin, glucagon and corticotrophin in mammalian tissues and cholinergic receptors in the electric organs of fish and eels. These studies have been based on the use of radioactive hormones or antagonists which bind very selectively to the receptor sites. Such binding if it is to be a valid method for identifying the receptors should show a very strict specificity, it should be saturable and indicate a finite and usually small number of receptor sites, and the affinity and rate constants for the binding reaction should correlate with the known biological properties of the receptor stimulant or antagonist molecule used. These criteria have been fulfilled in the instances just cited, and similar approaches have been successfully used to identify cholinergic muscarinic binding sites in mammalian brain, glycine receptor sites in spinal cord and receptors for morphine and other opiate drugs in brain (Hiley *et al., Biochem. J.,* **127,** 86P; 1972; Young and Snyder, *Proc. natn. Acad. Sci. U.S.A.,* **70,** 2832; 1973; Pert and Snyder, *Science, N.Y.,* **179,** 1011; 1973).

Cuatrecasas and colleagues, however, in last week's issue of *Nature,* (**247,** 92; 1974), illustrate the many pitfalls that await the unwary in using this apparently simple experimental approach for identifying receptor structures. Tritium-labelled noradrenaline of high specific activity has been available for some years, and might seem to offer a simple approach for labelling and identifying catecholamine receptors in mammalian tissues. Indeed Lefkowitz and his colleagues (*Proc. natn. Acad. Sci. U.S.A.,* **68,** 1773; 1971; *J. biol. Chem.,* **248,** 342; 1973) have claimed that the binding of ^{3}H-noradrenaline to fragments of cell membrane in microsomal fractions from mammalian heart and liver represents a specific binding to β adrenoreceptors in these tissues. Cuatrecasas *et al.* have carefully assessed this claim and their article clearly refutes it.

The binding of labelled noradrenaline to membrane fragments from liver, heart and fat cells or to intact fat cells was saturable, but the number of binding sites present in fat cells was three to four orders of magnitude greater than the number of insulin or glucagon receptor sites measured previously in these cells. Furthermore, the binding of ^{3}H-noradrenaline did not obey the strict specificity that would be predicted if this binding did represent labelling of β adrenoreceptors. For example, the non-radioactive (+) and (−) stereoisomers of noradrenaline had identical affinities as competitive antagonists of ^{3}H-noradrenaline binding. The affinity constant for such inhibition was more than 1μM, whereas the apparent affinity constant of (−) noradrenaline at β adrenoreceptors in fat cells was less than 0.1 μM, and (+) noradrenaline was at least one thousand times less potent in eliciting β-adrenoreceptor responses. ^{3}H-noradrenaline binding was also antagonised quite effectively by various catechol compounds, including pyrogallol and catechol acids, none of which have any activity at all as β-adrenoceptor stimulants, nor do they antagonise the receptor actions of (−) noradrenaline or isoprenaline. On the other hand, neither the non-catechol compound soterenol, which is a potent stimulant of β adrenoreceptors, nor the β-adrenoreceptor antagonist drug propranolol had any marked inhibitory effects on the binding of ^{3}H-noradrenaline.

It is thus clear that the structure responsible for the membrane binding of ^{3}H-noradrenaline is not identical with the β receptor for catecholamines. Indeed the specificity of these binding sites for catechols and their sensitivity to known inhibitors of the enzyme catechol-0-methyl transferase (pyrogallol, tropolone, quercetin) lead Cuatrecasas *et al.* to conclude that these binding sites more probably represent a membrane-bound form of this enzyme, known to exist in the microsomal fractions of the tissues studied.

The use of labelled hormones and neurotransmitters or their antagonists is likely to remain a most fruitful approach to identifying elusive membrane-bound receptor sites. But since such receptors are present in most tissues in extremely small numbers such potential labels must bind with extremely high affinity, must be available with extremely high specific activity and must obey very precise specificity rules in order for this approach to be valid. The hunting of the receptor snark can otherwise all to easily lead to boojums.

Selective adhesion and retinotectal specificity

from a Correspondent

The development of the brain involves the segregation of vast numbers of cells into precisely delineated subpopulations which are linked by highly selective neuronal connections. The mechanisms responsible for the formation of specific nerve connections have been analysed, most extensively in the retinotectal system of lower vertebrates: the axons of retinal ganglion cells connect selectively at local tectal sites to produce a map of the retina across the surface of the optic tectum. The most popular hypothesis that seeks to account for the discrimination in intercellular recognit[illegible] that such selective connections impl[illegible] that due to Roger Sperry, who s[illegible]gested, some 30 years ago, that cellular differentiation in the nervous system extends beyond the level of neuronal populations to that of the individual neurones themselves. The differentiated neurone acquires a characteristic cell surface label which participates in selective intercellular recognition and the formation of synaptic connections.

This hypothesis of neuronal specificity has withstood the test of time with remarkable success. Recent work has concentrated not so much on the hypothesis itself as on the rules by which such labelled neuronal arrays interconnect. The experimental paradigm adopted to examine the rules involves the surgical creation of relative size disparities between the innervating cell population and its target. Thus the patterns of connection that result when half a retina is caused to innervate a whole optic tectum or, conversely, when a whole retina feeds into a tectum half of which has been removed, have been described. The interpretation of such results has, however, run into a conceptual problem. One does not know whether the altered pattern of connections that is frequently found reflects altered neuronal labels, occurring as the direct result of experimental interference with a neuronal population or whether, alternatively, the neuronal labels themselves are unchanged by the operation. In this second case, the altered connection pattern might indicate the presence of a competitive mechanism in the formation of synaptic connections which are, then, determined not solely by the 'specificity labels' the[illegible] neurones carry but also by the context in which the two extant neuronal populations are interconnecting (Gaze and Keating, *Nature,* **237,** 375; 1972). The inability to distinguish between these two alternatives will persist until the appearance of an experimental design in which it is possible to deduce the nature of the neuronal labels independently of the formation of synaptic connections by the neurones.

One must await either the identifica[illegible]n of the 'specificity molecules' or, alternatively, an assay system which reveals their presence by a criterion other than the formation of synapses. What might be the first, and very exciting, step in the direction of such an assay is provided by the very elegant experiments of Barbera, Marchase and Roth (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2482; 1973).

Building upon earlier work which had demonstrated differences in adhesability between cells from different tissues, and from different brain regions, Barbera, Marchase and Roth decided to investigate whether there is preferential adhesion between cells which will become [illegible]ronally linked as opposed to cells that [illegible] not neuronally link. In their assay system a ^{32}P-labelled cell suspension of either dorsal or ventral retina of embryonic chicks was placed in dishes containing both ventral and dorsal tectal halves. Cells from the dorsal retina were found to adhere preferentially to ventral tectum and cells from ventral retina adhered preferentially to dorsal tectum. This preferential adhesion is similar to the innervation pattern of the retinotectal system; dorsal retina normally connects with ventral tectum and ventral retina with dorsal tectum.

This interesting result is interpreted with appropriate caution by the authors. Indeed, some care is warranted fore it can be accepted that the cell face recognition phenomenon being onstrated here is the one involved in specific synaptogenesis. Only a small proportion of the cells demonstrated the preferential adhesion that the authors monitored; most of the cells were easily displaced by light washing. Of those cells that did display the preferential adhesion, the difference in number between those adhering to the 'correct' tectal half exceeded those in contact with the 'wrong' half only by a factor of two, which is rather low for a system in which the differential specificity of neuronal connections is, in most models, viewed as very high.

As to the question of whether the mechanisms involved in cell adhesion are those involved in synapse formation, it must be accepted that the greatest part of the work on selective cell adhesion has emphasised the tissue-specific nature of these adhesions. Thus retinal cells selectively adhere to retinal cells, cerebellar cells to cerebellar cels (see Luis and Glaser (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2794; 1973)). This tissue-specific aggregation probably involves quite different surface receptors from those involved in synaptogenesis, because most neuronal connections link different populations rather than cells of the same population. In this context it is interesting to note that retinal pigment cells display the same preferential adhesion to tectal halves as do the neural retinal cells, even though retinal pigment cells are not neurones and most certainly do not form synaptic connections with the tectum.

Despite these caveats, this work of Barbera *et al.* is a most promising advance in attempts to understand the mechanisms of selective cell recognition. Such mechanisms will throw light on the formation of tissues and these experiments suggest that similar processes may underlie the elaboration of the intricate pattern of synaptic linkages that characterises the functioning nervous system.

Endemism and environmental stability

from our Plant Ecology Correspondent

ENDEMIC organisms and the problems underlying their origin and survival have a peculiar fascination for biogeographers. As long ago as 1882 Engler had postulated that there are basically two types of endemics, ancient ones (palaeoendemics) and those of recent origin (neoendemics). Various criteria have been used for their differentiation, the most effective being the geographic proximity of closely related species. Palaeoendemics are normally disjunct in distribution, occurring in situations well isolated from similar species. Neoendemics, on the other hand, often have many closely related species in the same or adjacent areas.

Stebbins and Major (*Ecol. Mongr.*, **35**, 1; 1965) analysed the flora of California, where roughly a third of the indigenous plants are endemic, and concluded that the palaeoendemic species are chiefly found in either markedly damp or distinctly dry environments, whereas intermediate climatic regimes are typified by neoendemics. They explain this by suggesting that palaeoendemics are found only in stable climatic situations whereas an unstable climate is conducive to rapid extinction and evolution, resulting in the production of neoendemics.

Ultimately, the demonstration that long-term climatic stability is associated with palaeoendemism is in the hands of the palaeoecologist. Meyer (*Ecology*, **54**, 982; 1973) has now accomplished this in the Cuatro Ciénegas Basin in northern Mexico, another area rich in endemics. The Cuatro Ciénegas Basin lies at an altitude of 740 m and is surrounded by mountains rising to heights in excess of 2,500 m. Many aquatic animals are endemic in the basin, including nine species of fish, three isopod genera and thirteen species of hydrobiid snails. The character of this fauna suggests that long-term isolation, perhaps accompanied by climatic stability, has resulted in its survival and development. In other words, these organisms are palaeoendemics.

Meyer has analysed palynologically two cores from the central area of the basin in order to reconstruct the environmental history of the region. One of these cores, which was taken from a spring-head mire, reaches a depth of 13 m, and radiocarbon dating on material between 11 m and 13 m gave results of >31,400 BP and >26,800 BP. The record thus goes back to the middle of the last (Wisconsin) glacial advance, at which time the area would have been experiencing pluvial conditions.

The pollen diagrams are remarkably uniform and give no evidence of rapid climatic fluctuations. The main fluctuations are in the pollen of grasses and the Chenopodiaceae / Amaranthaceae group, which probably reflect local changes in soil salinity and hydrology rather than climatic change. Modern pollen grain studies in the region indicate that tree pollen (mainly *Pinus*, *Quercus* and Cupressaceae) is derived largely from the montane *Pinus ponderosa* forests and Compositae pollen comes mainly from the mixed xerophytic communities and creosote bush savannah of the basin floor. Since the tree pollen:Compositae ratio remains fairly constant throughout the profile, it is reasonable to postulate a long term stability in these major vegetation types.

In this particular locality it is therefore possible to associate a high incidence of palaeoendemism with a history of environmental stability, thus providing support for Stebbins and Major's hypothesis.

Some somatic cell variants are mutants

from a Correspondent

ARE somatic cell variants true mutants, that is, are they really the result of stable and hereditary changes in nucleotide sequence? This question, which surely has disturbed the sleep of many a somatic cell geneticist, receives two positive replies in the November issue of the *Proceedings of the National Academy of Sciences*.

First, Thompson, Harkins and Stanners (**70**, 3094), continuing the Toronto group's work on temperature-sensitive (*ts*) variants, report that one of their *ts* Chinese hamster cells, *ts*H1, has a *ts* leucyl-transfer RNA synthetase. Mutant *ts*H1 grows normally at 34° C, but after shift up to 39.5° C, cell division stops and the cells disintegrate within 24 h. The mutant shows no subclone variation, has a low reversion frequency which is increased by exposure to mutagens such as ethyl methanesulphonate, and is recessive in cell hybrids. The clue that *ts*H1 has a primary defect in protein synthesis came when the rates of DNA, RNA and protein synthesis were examined after cells were placed at the nonpermissive temperature. Both DNA and RNA synthesis decline with a half-life of between 5–8 h; notably, protein synthesis shuts off almost immediately and is down to 5% of control values by 1 h.

Following this lead, Thompson *et al.* looked for various amino-acylated tRNAs by feeding cells ^{14}C-amino acids in the presence of cycloheximide and actinomycin D. Wild-type cells and a temperature-resistant revertant showed equal amounts of leucyl-tRNA at both 34° C and 40.5° C; *ts*H1 had normal amounts of all the amino acyl-tRNAs at 40.5° C, except leucyl-tRNA which was reduced more than 100 times. Direct assay *in vitro* of the leucyl-tRNA synthetase from *ts*H1 showed that it is the synthetase itself which is *ts*.

The second report, by Sharp, Capecchi, and Capecchi (**70**, 3145), is a study of the properties of the favourite enzyme of the somatic cell geneticist—hypoxanthine phosphoribosyl transferase (HPRT)—in variants of the mouse L cell. Cells that have a normal HPRT are extremely sensitive to the purine analogues, 8-azaguanine (8AG) and 6-thioguanine; revertants can be isolated using the Littlefield technique of blocking *de novo* purine biosynthesis with aminopterin and simultaneously providing hypoxanthine and thymidine ('HAT' selection). While looking for nonsense suppressors, Sharp *et al.* examined the kinetic properties and heat stability of HPRT among such HAT-resistant revertants. Several revertants grew equally well in both medium used to isolate HPRT-negative cells (8AG) and in medium used to isolate HPRT-positive revertants (HAT). These revertants had high concentrations of HPRT.

Initially, this seems to be a surprising, if not a slightly disturbing, result, though it would be expected if the revertant enzyme had a decreased affinity to 8AG, but had the normal K_m for hypoxanthine. This is precisely what Sharp *et al.* report for one such revertant, suggesting that a structural change has occurred in the enzyme. Another class of revertants possessed a very heat-labile HPRT, again providing strong evidence of structural changes in the enzyme as the result of mutation.

These two reports, taken together with previous findings of 8AG-resistant variants that contain material that cross-reacts immunologically with HPRT but have no enzymatic activity (Beaudet *et al.*, *Proc. natn. Acad. Sci., U.S.A.*, **70**, 320) and α-amanitin-resistant mutants due to an altered RNA polymerase II (Chan *et al.*, *ibid.*, **69**, 3119), should help to quiet the critics. It seems that at least some variants are mutants.

Analytical techniques for museums

from a Correspondent

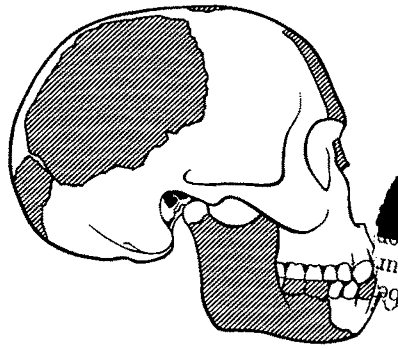
THE Society for Analytical Chemistry (Midlands Region) recently cooperated with the United Kingdom Group of the International Institute for Conservation in organising a symposium at the Birmingham Museum and Art Gallery on December 4. The scope of the contributions concerned both the present types of chemical analytical methods used in museum laboratories and also reviews of techniques which, although used increasingly in chemistry research in general, may also have applications to the examination of museum objects.

B. W. Fitzsimmons (Birkbeck College, London) described the theory and practice of Mössbauer spectroscopy and its applications to the study of ^{57}Fe and ^{117}Sn nuclei. As this technique gives information on the chemical environment of iron and tin, its potential use in museums is in the examination of clays and iron oxide pigments which may be complex mixtures of ferrous and ferric compounds. M. Thompson (University of Technology, Loughborough) dealt with photoelectron spectroscopy. Using X-ray excitation all elements except hydrogen can be detected in small samples, and it is possible to deal with many mixed oxide systems. The extreme sensitivity and high selectivity of the antigen-antibody reactions of, for example, proteins in immunological methods (J. N. Miller, University of Technology, Loughborough) which are already used in forensic science and food science suggest that they could be applied to paintings and other art work to reveal the media used by the artist. A key issue is whether antigen activity survives over long periods and this requires investigation.

After descriptions of potential new techniques, the methods used at present and results obtained in different museum laboratories were then described. J. Mills (National Gallery, London) has used infrared spectrometry and chromatography, principally GLC, to identify organic materials in art objects. Organic materials encountered in antiquities, especially paintings, are often complex natural products, but GLC of terpenoids (that is, resins) has provided new information on their identification and the chemical changes undergone over long periods. Ancient bronzes and faience in numbers running into the thousands have been analysed by H. McKerrell (National Museum of Antiquities of Scotland) using the version of non-dispersive X-ray fluorescence which he has developed. A rapid non-destructive method such as this has gre[illegible] potential for analytical surveys of large groups of museum objects. Such analyses have an important bearing on basic archaeological problems of trade contacts and sources of raw materials such as tin. In another laboratory (M. J. Hughes, Research Laboratory, British Museum) a combination of qualitative spectrographic and quantitative atomic absorption analysis has been used, because these methods are sufficiently sensitive for analyses of the small samples only which can be taken from museum objects.

Where expensive analytical equipment is not available, J. Hedley and A. Cumming (Courtauld Institute of A[illegible] London) described how opti[illegible] mineralogy, microchemical analysis and spot tests can be applied to inorganic materials used in paintings, and for organic compounds solubility tests and selective staining have been successfully applied.

Piltdown Man



THE Piltdown Man hoax still arouses curiosity and indeed was the subject of a recent British television programme some 60 years after the bits of skull and jawbone were found in a remote corner of Sussex. The British Museum (Natural History) has therefore done a service to the ordinary person who likes a scientific detective story, by producing a slim guide (*The Piltdown Man Hoax*, Palaeontology Leaflet No. 2, pp. 6; 7p) which sets out simply how the Piltdown remains came to be found, names the persons chiefly responsible for identifying the fragments, describes how the hoax was exposed at the museum and elsewhere between 1949 and 1953 and explains how, in 1973, the museum can say confidently "none of the *Eoanthropus* fragments can be considered fossil or in any way part of man's ancestry".

Weather and the Earth's magnetic field

J. W. King

Appleton Laboratory,* Ditton Park, Slough SL3 9JX, England

A comparison of meteorological pressures and the strength of the geomagnetic field suggests a possible controlling influence of the field on the longitudinal variation of the average pressure in the troposphere at high latitudes. If so, changes which occur in the pattern of 'permanent' depressions in the troposphere as the magnetic field varies (for example, as the non-dipole component of the field drifts westwards) may be accompanied by climatic changes.

I HAVE recently suggested[1] that regions of low atmospheric pressure observed near the magnetic poles occur because these regions, which are linked magnetically to the interior of the magnetotail, are strongly shielded against the incursion of olar particles. Although the mechanisms by which energetic particles may affect the troposphere are unknown, in this paper I describe the possible influence of the Earth's magnetic field on the height of the 500 mbar level in the regions surrounding the northern and southern magnetic poles. It will also be shown that certain features of the 'permanent' atmospheric pressure system seen to have moved westwards during some decades of the present century; this movement may be associated with a corresponding westward drift of the magnetic field pattern.

Figure 1 shows the average height of the 500 mbar level for January in the northern hemisphere[2]; the contours exhibit the typical northern hemisphere winter pattern of two lows, one near 80°W and the other near 130°E. Other examples of average pressure maps for the northern hemisphere have been published[3] and they all show a highly elongated or 'dumb-bell-shaped' low at high latitudes.

Comparison with magnetic parameters

Various theories[2] have been advanced in order to explain the existence and location of the two lows observed in the northern hemisphere, but theoreticians working in this field do not seem to have taken into account the fact, pointed out by other authors[4-9] in the past, that the Earth's magnetic field and the behaviour of the lower atmosphere may be connected in some way.

Figure 2 contains a map[10] showing contours of constant magnetic intensity, B, of the Earth's magnetic field (for middle and higher latitudes) at an altitude of 400 km in 1965; the northern hemisphere data are replotted in the polar plot shown in Fig. 3. The height for which the magnetic data are presented was chosen arbitrarily; the contours for lower altitudes would not have significantly different shapes, merely different B values.

A comparison of the longitudinal variations, at 60°N, of the 500 mbar data from Fig. 1 and the magnetic B data from Fig. 2 is shown in Fig. 4. The similarity between the two curves is striking except that the magnetic-B curve is displaced about 25° towards the west. Although the meteorological data relate to an earlier epoch (1918–1958) than the magnetic data (1965), no attempt has been made to correct the magnetic data for the well-known westward drift[11,12] of the non-dipole component of the Earth's magnetic field; part of the phase difference between the two curves would be removed by taking this into account. (A comparison of magnetic dip or magnetic declination maps from different epochs of the present century shows that the magnetic field patterns are rotating westward on average about 3° per decade; the drift is by no means uniform over the Earth's surface and it varies from decade to decade). The remaining phase difference may arise because of a complicated phase relationship between the atmospheric response and the modulating force imposed by the unknown magnetic-field-dependent 'driving force.'

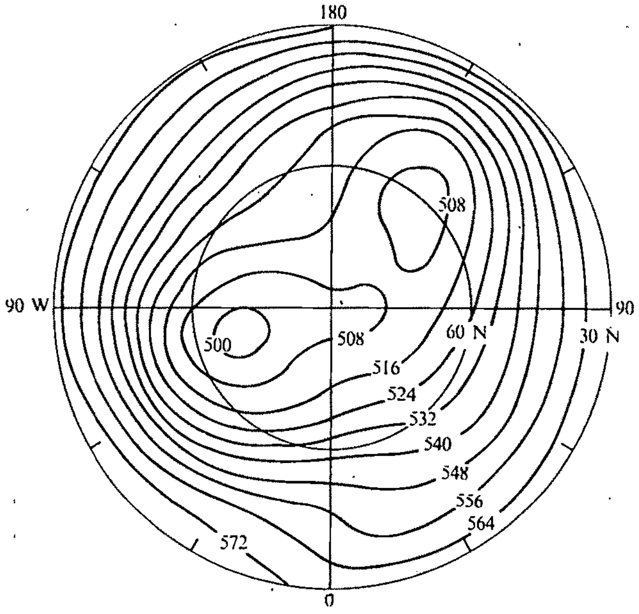


FIG. 1 Northern hemisphere polar plot showing the average height (decametres, dam) of the 500 mbar level for January. (After Palmen and Newton[2]).

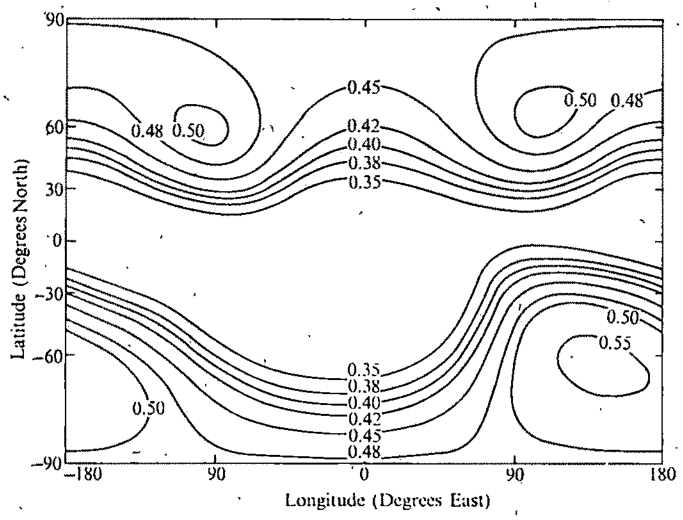

FIG. 2 Map showing contours of constant magnetic field strength B calculated for 400 km, 1965. (After Stassinopoulos[10]).

It should be noted from Fig. 4 that the magnitude of the 500 mbar height change associated with the magnetic field is of the order of 250 m. Comparison of the meteorological data (Fig. 1) and the magnetic data (Fig. 2) reveals that the pressure lows are centred on latitudes of 70° and 62° whereas the magnetic-B maxima occur at latitudes of 61° and 66° respectively.

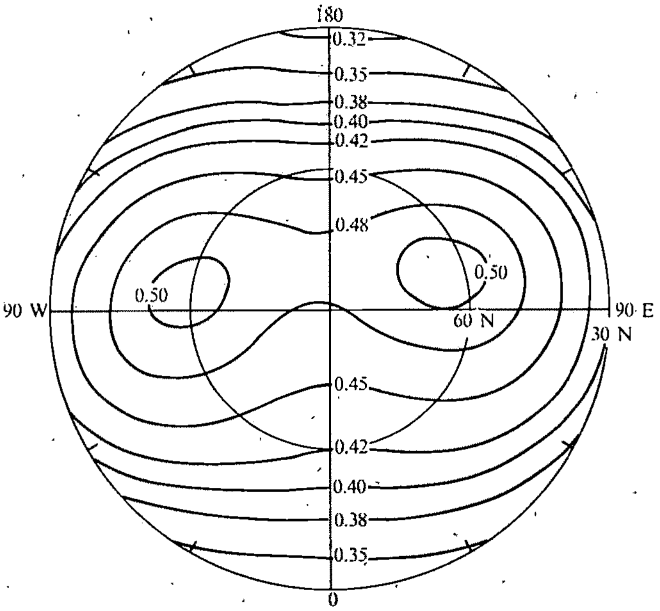

FIG. 3 Northern hemisphere polar plot showing contours, drawn from Fig. 2, of constant magnetic field strength for 400 km, 1965.

Figure 5 contains maps showing the height of the 500 mbar winter isobars over most of the northern hemisphere for epochs centred on 1933 and 1951 respectively. (The older data were obtained from ref. 13 and related to the December–February season. These data were compiled from observations reported in thirty-three documents, ten of which indicated in their titles the years for which the data applied; the average of these years was 1933. The other twenty-three documents had an average publication date of 1938 and it appears reasonable to conclude that the results are representative of years around 1933. The more recent data[14] related to January during the years 1949–53).

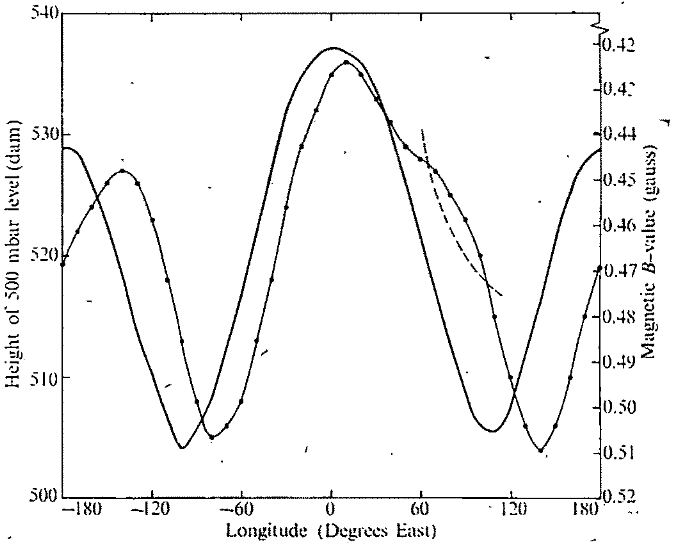

FIG. 4 Curves showing: •—•, the longitudinal variations at 60°N of the height of the 500 mbar level (from Fig. 1); —, the magnetic field strength (from Fig. 2). The short broken curve draws attention to some of the pressure data which may be anomalously high. The magnetic data relate to 1965 and the meteorological data to the epoch 1918-58.

Although statistically stronger evidence would be desirable, Fig. 5 does indicate that the average high-latitude pressure distribution appears to have moved westward by about 12° between 1933 and 1951; this angle is greater than that through which the Earth's magnetic field pattern rotated during the same period. Further information about the apparent westward rotation of the average pressure system is shown in Fig. 6 which relates to 60°N over the western hemisphere. Examination of the longitudes at which the maxima and minima occur shows that, averaging over summer and winter and heights between 300 and 700 mbar, the average pressure system moved about 15° westward between 1933 and 1951. It should be pointed out that the

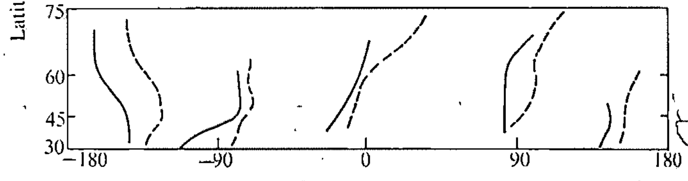

FIG. 5 Maps of the height of the 500 mbar isobars in winter. Upper: December-February, for an epoch centred on about 1933. The contours range from 500 to 567 in eleven steps of 6.1 dam. (After ref. 13). Middle: January, for the five-year period centred on 1951. The contours range from 500 to 570 in seven steps of 10 dam. (After ref. 14). Lower: Curves showing the positions of the crests and troughs appearing in the upper two sections. - - -, 1933; —— 1951.

recent data[14] related only to January or July whereas the older data[13] are for the three-month periods December–February or June–August; although significant differences exist between the average pressure distributions for different seasons, examination of all the maps available to the present author indicates that the seasonal variations cannot vitiate the conclusion that some parts of the average pressure system appear to be drifting slowly westward.

In the southern hemisphere the magnetic invariant pole is situated at a longitude of 125°E. It is well known that the geomagnetic contours surrounding the south magnetic pole are much more circular than the highly elongated ones around the northern pole and, therefore, the magnetic field should not be expected to produce meteorological effects at two longitudes in the southern hemisphere. Lamb (ref. 3, page 29) has published a polar diagram showing the mean height of the 500 mbar surface in the southern hemisphere; the low at the centre of the system is slightly displaced from the geographic pole, along the 120°E meridian. Figure 7 has been obtained from Lamb's plot and shows the latitudinal variation of the pressure down the 120°E meridian, across the geographic pole and up the 60°W meridian. The effect of the assumed magnetic-field-dependent mechanism seems to be a reduction in the height of the 500 mbar surface by a maximum of 140 m at 60°S. Figure 2 shows that the highest B-values in the southern hemisphere at 120°E also occur at 60°S; the height of the 500 mbar level is thus most reduced at the latitude where the magnetic field is strongest.

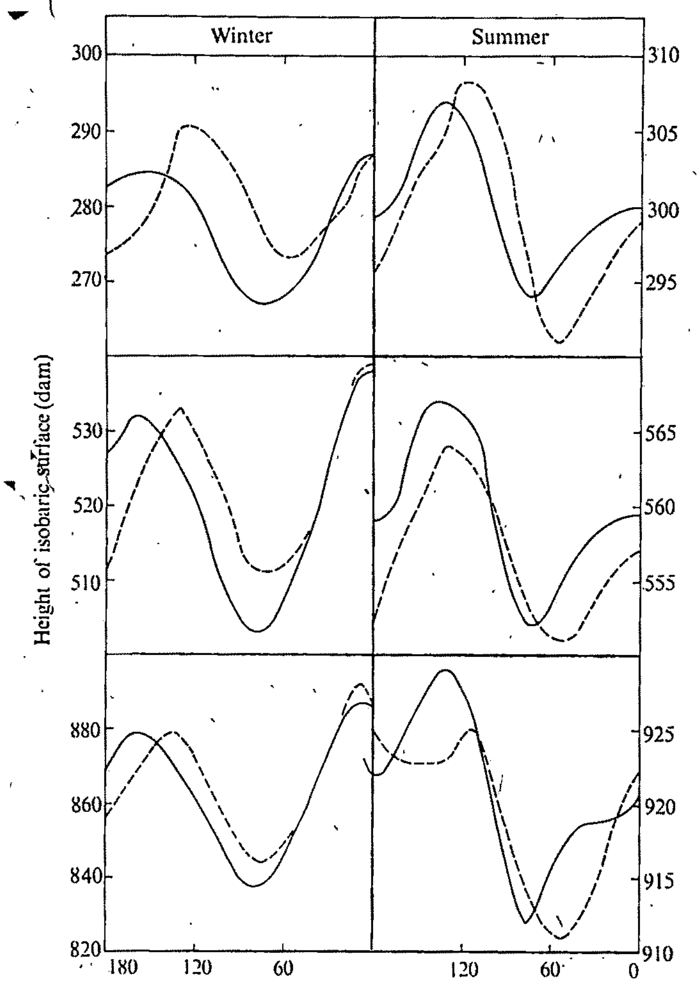

Fig. 6 Longitudinal variations of the height (dam) of the 700 (top), 500 (middle) and 300 (bottom) mbar levels in winter and summer for two epochs. – – – –, 1933; ——, 1951. (refs 13, 14).

Implications and applications

I conclude that: (a) the Earth's magnetic field possibly influences the average tropospheric pressure system at high latitudes; and (b) the average pressure system seems to move westwards as the magnetic field rotates. The evidence relating to the second point is less convincing and there is clearly a need for further comparisons of meteorological data from widely spaced epochs for which reliable maps of magnetic field strength are also available. Even though Fig. 5 may not provide conclusive evidence about the westward motion of the pressure system, it does show that the pressure contours are very similar to the magnetic contours drawn in Fig. 2.

The large geographical extent of the permanent depressions results in considerable meridional air motion; warm air from lower latitudes at the longitude of a depression will move towards higher latitudes to the east of the depression. Clearly, if the longitude of one of the northern hemisphere depressions drifts towards the west the climate over much of the northern high-latitude region will alter. It should be noted, in this context, that the magnetic declination at London and Paris was zero in about 1660 (refs 15, 16); the magnetic field configuration then prevailing in the northern hemisphere was obviously very different from the present one and it is interesting to note, therefore, that Europe and certain other parts of the northern hemisphere experienced a "Little Ice Age"[3] during the period 1550–1700 AD. It would be expected, if the average tropospheric pressure systems are indeed controlled by changes of the Earth's magnetic field, that various climatic phenomena which have occurred in the past should be associated with changes in the magnetic field. Evidence that this is so will be presented elsewhere.

The phase difference between the longitudinal pressure and magnetic variations (Fig. 4) can only be partially explained by the westward drift of the Earth's field. I suggest that the remaining difference (between the phase of an unknown magnetic-field-dependent driving force and the response of the atmosphere) may be caused by Coriolis force

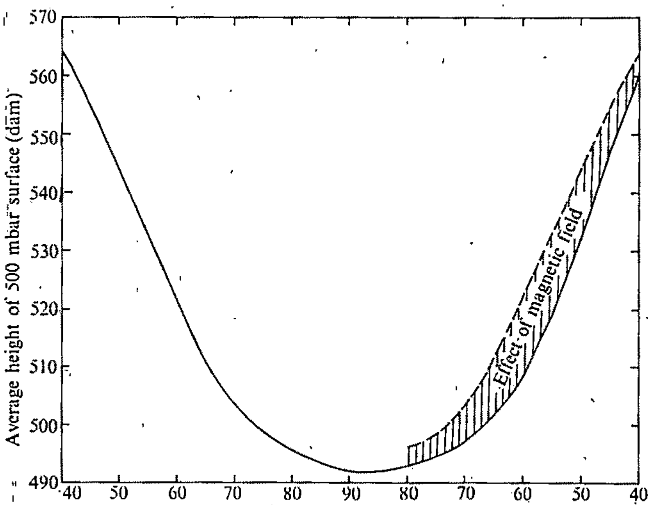

Fig. 7 Latitudinal variation of the height of the 500 mbar surface down the 120°E meridian and up to 60°W meridian. The difference between the values along the two meridians is greatest near 60°S. —— Observed; – – –, mirror image of data from 60°W meridian.

and by the inertia and viscosity of the air. If Coriolis force is important in this connection, the phase difference should be expected to vary with latitude, probably becoming greater at lower latitudes. The phase difference will also, of course, depend on the process by which energy is imparted to the atmosphere and thus the observed phase differences, when the effects of Coriolis force and so on have been subtracted, may constitute an important clue in the search for trigger mechanisms that enable changes in the solar wind or other forms of solar radiation to affect the vast mass of the lower atmosphere.

The meteorological data in Fig. 4 exhibit some irregular behaviour which is most pronounced in the longitude range 70 to 100°E, exactly the range covered by the highest mountains of Central Asia. If the longitudinal variation of the average height of the 500 mbar level at 60°N is dependent on the Earth's magnetic field, it may not be necessary to invoke orographic (related to mountains) or thermal effects associated with topographical phenomena such as land/sea boundaries to explain the major features observed. Possibly the main effect of mountains on the average height of the 500 mbar level at 60°N is the small increase, approximately 30 m, observed at the longitude of the mountains of Central Asia.

The conclusion that some unknown magnetic-field-dependent mechanism seems to modulate the tropospheric pressures by an amount which is greater in the north than in the south is particularly interesting because it is known[17] that the intensity of auroral optical emissions, produced by energetic particles impinging on the atmosphere, is 30% greater in the northern than in the southern hemisphere.

It has recently been demonstrated that changes in the sector structure[18] of the interplanetary magnetic field, and also changes of geomagnetic activity[19,20], are correlated with the depths of meteorological troughs crossing North America. Other workers[21] have also reported that conditions in the troposphere appear to be abnormal near the times of geomagnetic disturbances. The explanation of these results may be similar to that of the marked influence which the Earth's magnetic field appears to exert on the troposphere. Some of the studies[22] involving correlations between the troposphere and the sector structure have suggested why solar-weather relationships established empirically for certain periods are not observed during other epochs.

The problem of the trigger mechanism by which small amounts of energy from the solar wind can affect the atmosphere provides an interesting field of research. Roberts and Olson[19] have suggested that cirrus cloud formation following ionisation produced by X-rays emitted during aurorae may be important; a difficulty about this suggestion is that auroral bremsstrahlung do not normally penetrate to tropospheric heights. Energetic solar protons and γ rays associated with heavy particles are, however, capable of reaching lower heights than the bremsstrahlung and it may be that they affect the atmospheric pressure in some way. It is known, alternatively, that changes in the solar radiation affect the stratospheric ozone concentration[23,24] and perhaps, therefore, the thermal balance of the lower atmosphere.

It seems possible that the solar wind may influence the behaviour of the Earth's atmosphere if the accretion of solar wind protons results in the production of water vapour in the stratosphere[25,26]. De Turville[25] suggested that all the water in the oceans might have been formed in this way, but concluded later[27] that this was not the case; the considerations which led to the withdrawal of the suggestion involved the rate at which water vapour would be produced rather than whether the process occurred at all. Wasson and Junge[28] concluded: "The importance which is attached to an extra-terrestrial orgin for even part of the stratospheric water-vapour means that water-vapour measurements, especially in the polar stratosphere, could be of great scientific value". It is well known that the penetration of the solar wind to the near-environment of the Earth depends on the terrestrial magnetic field and it would seem worth examining, therefore, whether the spatial distribution water vapour in the stratosphere, and hence the thermal balance of the lower atmosphere, is also dependent on the field. If the relatively low atmospheric pressures that occur in regions of high magnetic intensity are a consequence of shielding by the magnetic field against direct injection of certain solar wind particles it should be expected that, since the angle between the magnetic dipole and the solar wind is very different in summer from that in winter, solar-weather relationships will show marked seasonal changes. Roberts and Olson[20] have reviewed evidence which clearly shows that this is the case.

Although the evidence presented in this paper cannot be construed as proof that the Earth's magnetic field and the average tropospheric pressure patterns are related, it does suggest that more work on this problem should be undertaken.

I propose that the field of research involving inter-relatio ships between meteorological phenomena and processes d pending on the Earth's magnetic field should be known as 'magnetometeorology'.

I thank Drs W. C. Bain, H. H. Lamb, J. A. Saxton and D. M. Willis for comments and Dr D. L. Croom for drawing my attention to the stratospheric water vapour problem[25–28].

Correlated physiological changes, and structural and functional changes in myosin, following cross-reinnervation of cat fast-twitch and slow-twitch muscles, indicate that the myosin phenotype is controlled through the nervous system.

THE changes which occur in the isometrically recorded contractions of cross-reinnervated mammalian fast-twitch and slow-twitch muscles are now well documented[1–3]. In many respects, the study of isotonic shortenings can, however, be more directly informative about changes in the contractile machinery. Close, using the rat[2,4], first clearly demonstrated that cross-reinnervation of the soleus (SOL, slow-twitch) and extensor digitorum longus (EDL, fast-twitch) muscles produced reciprocal changes in both the maximum speed of shortening (V_0) and the curvature of the force-velocity relationship. More recently Bárány and Close[5], using the rat, ave shown that the activity of the Mg^{2+}-dependent actomyosin ATPase also changes following cross-reinnervation, in a manner which parallels the alteration in V_0. These findings supported Bárány's earlier hypothesis[6] that the actomyosin ATPase activity is the rate limiting step which determines a muscle's maximum shortening velocity.

Isotonic studies of cross-reinnervated cat muscles have given less clear cut results than in the rat. While cross-reinnervation of fast-twitch muscle by a nerve formerly innervating soleus (a slow-twitch) muscle produced a marked reduction in V_0, as in the rat, cross-reinnervation of the soleus muscle produced a variable but usually small increase in V_0 (ref. 7). Studies of the muscle myosin Ca^{2+}-dependent ATPase activity showed this to parallel the changes in shortening velocity[8].

A further study[9] of the isotonic shortenings of cross-reinnervated cat muscles using soleus as the slow-twitch muscle but the larger head of the deep digital flexors, correctly called flexor hallucis longus (FHL) rather than the formerly used smaller head (flexor digitorum longus, FDL)[7] as the fast-twitch muscle, has led to results which are in general agreement with those obtained in the rat. In particular, following cross-reinnervation, the soleus muscle showed a marked increase in V_0, a change which was accompanied by a decreased curvature of the force-velocity relationship. It was then of interest to know whether, as in former cases, the ATPase activities of the myosins from these muscles mirrored their shortening velocities, and further whether the myosin light chains were altered following cross-reinnervation. These low molecular weight proteins, which are part of the enzymatically active "head" of the myosin molecule, are chemically different in normal fast-twitch and slow-twitch muscles and their electrophoretic mobilities provide a characterisation of the myosin phenotype[10–12].

The results described in this paper were obtained from the muscles of four cats which had been cross-reinnervated for approximately 12 months and which formed part of a larger physiological study[9]. The four animals were selected because they showed a purity of reinnervation by the crossed nerve in excess of 90%. As the muscles were required for biochemical studies, histological examination was not undertaken, the success of the cross-innervation being gauged by the purity of the reinnervation and the fact that on indirect stimulation the cross-reinnervated muscles developed a mean of 91% of the maximum isometric tension of the control muscles. It was noted, however, that the cross-reinnervated soleus muscles tended to develop somewhat more tension than their controls and the cross-reinnervated FHL muscles less.

The apparatus and methods used have been described fully elsewhere[13]. Fibre lengths were measured by the method of Al-Amood and Pope[14]. At the end of the physiological experiments the muscles were excised, blotted and weighed, then frozen in liquid nitrogen and stored at −20° C.

Myosin was prepared essentially as described by Bárány and Close[5]. The muscles were chopped finely with a razor blade and connective tissue removed, then homogenised in 30 mM KCl, 5 mM potassium phosphate at *p*H 6.7. The myofibrils were pelleted by centrifugation at 10,000*g* and the supernatant used to measure the absorbance of the Soret band at 417 nm (for quantitation of haem proteins). The myofibrils were washed twice more with 20 volumes of the same buffer, then extracted in a medium containing 0.3 M KCl, 0.15 M potassium phosphate, 5 mM MgATP, 0.1 mM dithiothreitol at *p*H 6.6 for 20 min at 4° C with gentle stirring. The extract was centrifuged at 27,000*g* for 10 min and the supernatant dialysed overnight against 30 mM KCl to precipitate the myosin, which was collected by centrifugation at 10,000*g* for 15 min. The myosin precipitate was washed with 30 mM KCl to aid removal of excess nucleotides, dissolved at 0.6 M KCl, 20 mM potassium phosphate at *p*H 6.7 and clarified by centrifugation at 40,000*g* for 30 min. Myosin was reprecipitated by dialysis against 30 mM KCl, 2 mM potassium phosphate and finally dissolved in 0.6 M KCl, 20 mM potassium phosphate at *p*H 6.7 and clarified once again.

The myosin concentration was estimated by absorbance at 280 nm assuming as an extinction coefficient that obtained for rabbit fast muscle myosin ($E_{280}^{1\%}=5.60$ (ref. 15). The extinction coefficients measured for myosins prepared as described from frozen cat muscles were up to 25% higher than this value and SDS gels showed the presence of contaminating actin, which could not be completely removed without unacceptable loss of myosin. For this reason, in some preparations the extracted myofibrils were centrifuged at 165,000*g* for 4 h to pellet contaminating actin. The myosin was precipitated by dialysis against low salt, redissolved in 0.6 M KCl, 20 mM potassium phosphate at *p*H 6.7, and subjected to a second ATP dissociation followed by centrifugation at

* Present address: Department of Physiology, School of Medicine, The Center for the Health Sciences, Los Angeles, California 90024.

165,000g for a further 4 h to remove residual actin. Finally, the myosin was reprecipitated by dialysis, the precipitate washed to remove nucleotide and redissolved as above. These preparations, which were largely free of actin, gave extinction coefficients which were the same for both the SOL and FHL myosins ($E^{1\%}_{280}=6.2$, based on the Folin reaction using bovine serum albumin as standard). The need for accuracy in protein determination could be circumvented by the use of stopped-flow assays, which are independent of protein concentration. The molecular weight of myosin was taken as 470,000[16], and the molarity based on two equivalent structure units of 235,000 daltons. F-actin was prepared according to Kendrick-Jones *et al.*[17].

Solvent conditions for the different kinetic assays of the ATPase are described in Table 1 and Fig. 1. The steady state actin-activated Mg^{2+}-dependent ATPase was used most extensively. The Mg^{2+}-dependent ATPase was measured occasionally but required relatively large amounts of myosin. A further assay measured the rate of protein fluorescence increase when myosin was mixed with a large molar excess of ATP, using the stopped-flow fluorimeter technique of Bagshaw *et al.*[18]. With the experimental conditions used, the observed rate constant of this pseudo-first order reaction is directly proportional to the ATP concentration and independent of myosin concentration. This method has a second advantage that the observed rate is independent of small amounts of contaminating actin and thus two potential sources of error in comparing different myosins are eliminated. The percentage increase in fluorescence when ATP was mixed with fast-twitch and slow-twitch muscle myosins was taken to be the same, that is, 8±2% (Fig. 1).

Polyacrylamide gel electrophoresis in the presence of SDS was carried out according to Weber and Osborn[19]. The samples were mixed with a five-fold excess of SDS by weight and 1% β-mercaptoethanol and placed in a boiling water bath for 3 min. Aliquots of 50–150 μg were applied to 7 cm gels. Staining was in 0.2% Coomassie Brilliant Blue in 50% methanol, 10% acetic acid for 2 h at 45° C and the gels were destained initially in the same solvent and then in 5% methanol, 10% acetic acid also at 45° C.

Twitch time

The isometric contraction data were similar to those reported earlier[1,3,9] and showed that the twitch myogram of a cross-reinnervated FHL muscle slowed so that it came to resemble that of a normal or self-reinnervated soleus muscle and *vice versa*.

As has been reported previously[3], the increase in the twitch time of cross-reinnervated fast-twitch muscles is more marked than the decrease in the twitch time of cross-reinnervated soleus muscles, and this observation was confirmed in the present series with one exception. The cross-reinnervated soleus muscle of the experiment of May 18 showed a more marked speeding of its isometric twitch time than we have seen in any animal before or since. The normal (right) soleus of this cat had a contraction time of 87 ms and the cross-reinnervated (left) a contraction time of 25 ms. Because of the unexpectedness of this observation physiological studies were concentrated on the soleus muscles of this cat, and isotonic results were not obtained on either the normal or the cross-reinnervated FHL muscle.

The isotonic contraction results showed a reduction in the maximum shortening velocity of cross-reinnervated fast-twitch muscles as has been reported earlier[7]. But, contrary to this same report[7], we observed in the present experiments (and again particularly in the cat of May 18) a marked increase in the maximum shortening velocity of the cross-reinnervated soleus muscles (see Tables 1 and 2).

Table 1 Characteristics of Normal and Cross-reinnervated FHL and SOL Muscles from May 18 Cat

	N-FHL	X-FHL	N-SOL	X-SOL
* TP (ms)	29	54	87	25
† V_0	—	—	4.82	11.6
‡ Soret band	0.50	0.99	1.0	0.56
§ Rate of fluorescence change (Fig. 1) (s^{-1})	5.6 (3.3)	2.0 (1.2)	1.7 (1.0)	5.0 (2.9)
‖ Mg^{2+}-ATPase (s^{-1})	0.053 (2.9)	0.019 (1.05)	0.018 (1.0)	0.035 (1.95)
¶ Actin-activated Mg^{2+}-ATPase (s^{-1})	2.7 (10.0)	—	0.27 (1.0)	2.5 (9.3)

* TP, time to peak of isometric twitch (the time from the start of contraction until peak tension development).

† V_0, maximum unloaded shortening (muscle fibre lengths s^{-1}).

‡ Soret band, relative absorption (λ_{max} 417 nm) of haem proteins in the first extract of the blended muscle (see preparative procedures)[28,29].

§ Rate of fluorescence change was the observed rate when 12.5 ATP was mixed with the myosins as illustrated in Fig. 1.

‖ Mg^{2+}-dependent myosin ATPase activity using 2.5 mg [illegible] myosin measured in 0.6 M KCl, 5 mM $MgCl_2$, 50 µM dithiothreitol, 0.5 mM EGTA at pH 8.0 and 25° C initiated by addition of 0.4 mM ATP, using a radiometer pH-stat.

¶ Actin-activated Mg^{2+}-dependent myosin ATPase activity using 0.02–0.2 mg ml^{-1} myosin measured in 0.67 mM ATP, 23 mM KCl, 1 mM $MgCl_2$, 6.7 µM $CaCl_2$ at pH 8.0 and 22° C in a radiometer pH-stat, initiated by addition of 0.85 mg ml^{-1} actin. Insufficient X-FHL myosin was available to obtain a reliable actin-activated Mg^{2+}-ATPase activity, but such results as were obtained indicated the activity was comparable to that of the normal soleus myosin. The figures in brackets are values relative to the normal soleus.

Myosin activity

Before studying myosins from the cross-reinnervated muscles several control experiments were carried out on preparations of fast-twitch and slow-twitch myosins from normal cat muscles. ATPase activities of myosins isolated from fresh muscles were identical to those of myosins isolated from corresponding muscles stored at −20° C.

A further control experiment concerned the extractability of myosins from different muscles. Normal FHL and soleus muscles well cleaned of connective tissue were mixed in known proportions by weight (3:1, 2:2, 1:3) and the resultant myosins isolated. Kinetic analysis of the pure myosins and the mixtures gave activities which showed that each myosin was extracted essentially in proportion to its original content in the muscle (that is, the myosin from the 2:2 muscle mixture behaved as an equal weight mixture of pure FHL and soleus muscle myosins). This is an important result, since the yields of myosin from the muscles were variable and often rather low, particularly the cross-reinnervated FHL muscles. These low yields occurred with smaller muscles which seemed to contain a proportionally higher content of connective tissue, and whose myosins precipitated less quantitatively in low salt because of their relatively low concentrations.

The kinetic results from the myosins of the May 18 cat are summarised in Fig. 1 and Table 1. (N-FHL, S-FHL, and X-FHL are respectively normal, self-reinnervated and cross-reinnervated flexor hallucis longus muscles; N-SOL, S-SOL and X-SOL, normal, self-reinnervated and cross-reinnervated soleus muscles.) They show that cross-reinnervation has resulted in almost complete cross over from the kinetic viewpoint. This can clearly be seen in Fig. 1 when the observed rates are dependent solely on the type of myosin and not on its total concentration.

The physiological measurements indicated that in other experiments transformation was less complete and this was reflected in the actin activated Mg^{2+}-dependent ATPase

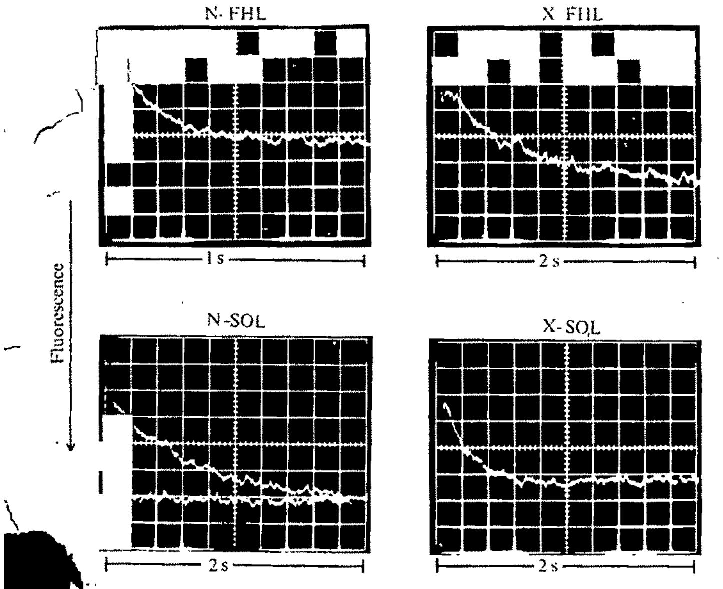

Fig. 1 Stopped-flow spectrophotometric record of the protein fluorescence increase when ATP is mixed with myosin isolated from normal and cross-reinnervated FHL and soleus May 18 cat muscles at 22° C. One syringe of the stopped-flow apparatus contained myosin (0.50 mg ml^{-1}), 2.1 µM in myosin 'heads' and the other 12.5 µM ATP. Both syringes contained 0.5 M KCl, 5 mM $MgCl_2$, 0.1 mM dithiothreitol, 0.2 mM EGTA and 50 mM Tris adjusted to *p*H 8.0 with HCl. Reaction chamber concentrations are recorded. The horizontal trace on the N-SOL myosin photograph was recorded a few seconds after the reaction was initiated and shows the protein fluorescence during steady state ATPase activity. Observed first order rate constants were obtained from the oscilloscope traces, and the mean values of a number of records for each myosin are listed in Table 1. The fluorescence stopped-flow apparatus, built by Professor H. Gutfreund and Dr D. W. Yates, has been described previously[18]. The protein was excited by light at 300 nm and the emitted light between 335 and 375 nm analysed. Measured in this way the percentage increase of protein fluorescence when ATP bound to myosin was 8±2%.

activities (Table 2), where the myosin from cross-reinnervated soleus muscle had $\leq$50% of the control (self-reinnervated) FHL activity. A striking feature of our results is the high activity ratio between the control FHL and soleus myosins from the May 18, August 30 and September 18 cats. (Compare, for example, ratios of approximately 2:1 obtained by Bárány and Close[5].) A lower ratio was obtained from the August 23 cat, where assays were carried out at higher ionic strength and lower actin concentrations. It was important to check whether the assay conditions were close to V_{max} for both proteins with respect to actin. This was shown to be the case by measuring the ATPase activity at several actin concentrations between 0.07 and 1.3 mg ml^{-1}, using the control myosins from the August 30 cat. The S-FHL activity showed a plateau above 0.3 mg/ml actin, while the S-SOL activity was >90% of V_{max} at 1.3 mg ml^{-1} actin. Thus the use of low ionic strength conditions and saturating actin concentration at 25° C produce activity ratios in excess of 10:1 for normal fast-twitch and slow-twitch muscle myosins.

Myosin light chains

Both the physiological and kinetic experiments show that cross-reinnervation can produce a reciprocal transformation of cat fast-twitch and slow-twitch muscles (Table 2), and the myosins were further examined by SDS gel electrophoresis to show the light chain distribution. Figure 2 shows the results for the May 18 cat. The positions of the three light chains characteristic of fast-twitch muscle myosin are shown by the rabbit light chain marker. The myosins from the N-FHL and X-SOL seem identical, so too do the myosins from the S-SOL and X-FHL, though here the number of bands observed in the light chain region is higher than expected. (Compare results with refs 11 and 12 for slow-twitch muscle myosins of the rabbit.) Attempts to eliminate some of these components by further purification of the myosins either by ammonium sulphate precipitation or on DEAE-cellulose columns in pyrophosphate buffers[20] did little to remove the additional bands, though the two fastest bands (Fig. 2*e*, *f*) were somewhat decreased in intensity. Purification by ion exchange chromatography was not used routinely because of the considerable loss of protein during the fractionation and subsequent concentration procedures. In spite of this marked heterogeneity in the light chain band pattern, the myosins from N-SOL and X-FHL were indistinguishable from each other in the light chain region and showed significant differences when compared with the myosins from S-FHL and X-SOL muscles. Similar observations were made for the other cats, showing the cross-reinnervation results in the production of myosins whose light chain mobilities on SDS gels are consistent with a cross over of myosin isoenzyme production.

Table 2 Characteristics of Muscles and Myosins from Cross-reinnervated Cats

August 23 cat	S-FHL	X-FHL	S-SOL	X-SOL
TP	30	51	75	37
V_0	16.3	6.51	6.27	11.1
Actin-activated Mg^{2+}-ATPase (s^{-1})	0.72	0.31	0.19	0.37
Physiological conversion		0.96		0.48
Biochemical conversion		0.77		0.34
August 30 cat				
TP	24.5	52	77	39
V_0	10.8	7.28	6.45	8.43
Actin-activated Mg^{2+}-ATPase (s^{-1})	3.86	0.83	0.20	0.88
Physiological conversion		0.81		0.46
Biochemical conversion		0.83		0.35
September 18 cat				
TP (ms)	31	58	95	45
V_0	13.6	7.58	5.07	8.34
Actin-activated Mg^{2+} ATPase (s^{-1})	2.12	0.71	0.20	0.50
Physiological conversion		0.71		0.38
Biochemical conversion		0.74		0.16

Definitions of TP and V_0 are given in the legend to Table 1. The physiological and biochemical conversions are estimates of the degree of conversion[8] calculated from the V_0 and actin-activated ATPase activities respectively. The physiological conversion for

$$\text{soleus} = \frac{[V_0(\text{X-SOL}) - V_0(\text{S-SOL})]}{[V_0(\text{S-FHL}) - V_0(\text{S-SOL})]}$$

$$\text{and for FHL} = \frac{[V_0(\text{S-FHL}) - V_0(\text{X-FHL})]}{[V_0(\text{S-FHL}) - V_0(\text{S-SOL})]}$$

For the September 18 and August 30 cats the actin-activated Mg^{2+}-dependent ATPase activities were measured using 0.2–1.6 mg ml^{-1} myosin under conditions described in Table 1. The actin concentration was 1.3 mg ml^{-1} throughout. The KCl concentration in the experiments with the August 30 cat was 19 mM instead of 23 mM. For the August 23 cat the assays were carried out using a 2 : 1 (w/w) ratio of actin to myosin and the assay conditions were 30 mM KCl, 2 mM $MgCl_2$, 0.5 mM ATP at *p*H 7.6.

The results described above show a correlation between the physiological changes that accompany cross-reinnervation of cat fast-twitch and slow-twitch muscles and both the kinetic and structural properties of the myosins obtained from these muscles. They confirm and amplify the results of Bárány and Close[5] with the rat and Samaha *et al.*[21] and Buller *et al.*[8] with the cat. In particular the experiment of May 18 demonstrates that in the cat an effectively complete cross over can occur not only in the actin activated Mg^{2+}-dependent ATPase activi-

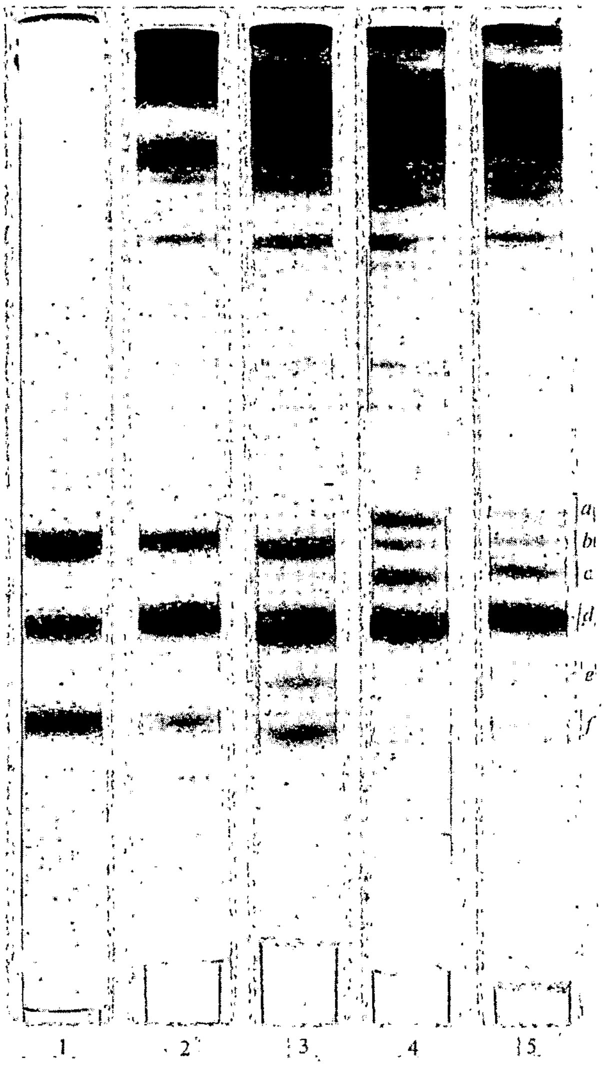

Fig. 2 Polyacrylamide gel electrophoresis of myosins from the May 18 cat run in the presence of SDS on 10% gels. 1, Rabbit myosin light chains; 2, N-FHL; 3, X-SOL; 4, N-SOL; 5, X-FHL. The letters *a–e* denote the light chain bands in the slow-twitch muscle myosin.

ties of the myosins (see ref. 8), but also in the light chain pattern observed by SDS gel electrophoresis of the myosins.

The biochemical methods used in this work for estimating actin-activated ATPase activities have differed somewhat from those described previously[5,8]. Other authors have attempted to retain conditions approximating those found *in vivo* and the actomyosin composition has reflected that observed in myofibrils, whereas we have used techniques to exhibit the maximum differences between the myosins in a variety of kinetic assays which are nevertheless related to important activities *in vivo*. Although attempts to mimic the *in vivo* situation inevitably fall far short of exactness, we see no reason to prefer one set of data to the other. On the other hand we would certainly not claim that our kinetic techniques provide a more precise indication of the *in vivo* situation. In particular we see nothing in the present results to invalidate the Bárány hypothesis[6], though the failure to obtain quantitatively similar ratios for the physiological and biochemical conversions (see Table 2) suggests that factors other than myosin ATPase activity may also play a part in determining a muscle's maximum shortening velocity. Previous reports[5,8] have also contained data on the Ca^{2+}-dependent ATPase activities of the myosins from cross-reinnervated muscles and similar assays were carried out on our myosin preparations, but the results did not show such dramatic differences between the fast-twitch and slow-twitch myosins as are recorded in Tables 1 and 2, and the cross-reinnervated muscle myosins were always intermediate in value between the control activities. This kinetic assay is particularly sensitive to modification of the myosin, for example, through thiol oxidation, and we are inclined to agree with Bárány and Close[5] that it is a less reliable method for distinguishing myosins from cross-reinnervated muscles. Furthermore, this assay has no physiological significance since the role of calcium *in vivo* is regulatory[22].

The complexity of the light chain gel pattern observed in Fig. 2 for cat myosins is greater than that reported for rabbit myosins. Both N-FHL and X-SOL myosins show additional minor bands when compared with rabbit light chains. Control preparations of rabbit soleus myosin show two bands whose mobilities correspond to molecular weights of 27,000 and 18,000[11,12,23] and our observations agree wi[illegible] these. Large scale preparations of myosin from normal [illegible] soleus muscles have, however, always given a pair of ban[illegible] in the 27,000 dalton region corresponding to *a* and *b* in Fig. 2, together wth a strong third band equivalent to *d*. Increased heterogeneity in the light chain region invariably occurred when the light chains were isolated from cat soleus myosin, yielding the additional bands (*c*, *e* and *f*) seen in Fig. 2 for the N-SOL and X-FHL myosins. These additional bands probably arise as a result of proteolytic degradation of the cat myosin.

The significance of the gels shown in Fig. 2 is to demonstrate the overall similarity between myosins from N-SOL and X-FHL muscles and to distinguish these from the N-FHL and X-SOL myosins. This can be most easily appreciated by the presence or absence of band *a*, which is characteristic of slow-twitch muscle myosin. Bands *b*, *d*, *e* and *f* cannot be distinguished by their mobilities alone from correspondin bands in the fast-twitch muscle myosins and, although th presence of bands *e* and *f* in N-SOL and X-FHL myosi may be attributed to proteolytic degradation, the presence of both myosin isoenzymes in the X-FHL cannot be ruled out. Unequivocal assignment of the proteins in these bands can only be made after further analysis of the light chains involved, and current studies on the thiol peptides present in the different light chains should provide unambiguous evidence for the identity of each component.

Other observations indicate that it is not only the light chain components that change following cross-reinnervation. Evidence has been adduced from the content of methylated histidine and lysine that the heavy chains of myosin also change in response to neural influence, and these preliminary studies[24] are supported by gel electrophoretic studies of heavy meromyosins produced from cross-reinnervated rat muscles[25].

All these results indicate that the myosin phenotype is controlled by the nervous system. At the present time it is not clear whether this control is exercised exclusively by the pattern of nerve impulses reaching the muscle, or whether other factors such as a trophic (non-impulse) influence also play a part. That the former is of considerable importanc has recently been demonstrated by experiments in whic myosin light chains characteristic of slow muscle have bee synthesised in response to long-term stimulation of rabbit fast-twitch muscle[26]. It has also been shown that long-term stimulation of cat fast-twitch muscle results in a marked decrease of the muscle's maximum shortening velocity[27]. These observations, together with the present results, certainly suggest that if an altered activation of muscle occurs following cross-reinnervation it might play a major role in the mechanical and biochemical changes which occur. It would be interesting to know if the electromyogram activity of muscles does change following cross-reinnervation.

We are grateful to the Science Research Council and the Muscular Dystrophy Associations of America for financial assistance.

Spectroscopic Variations in Cyg X-2

THE X-ray source Cyg X-2 has been optically identified with a fifteenth magnitude blue object[1]. Initial spectroscopic observations[2-4] revealed the presence of broad Balmer absorption lines, a narrow, strong Ca II K line and a narrow emission line of He II λ4,686. Radial velocity variations were evident, with the indication that the emission and absorption line velocities varied 180° out of phase. Photometric monitoring[4] showed the object to vary erratically on a time scale of minutes. Later spectroscopic observations[5,6] confirmed the changes in radial velocity, but no certain evidence of binary motion could be demonstrated. A more recent spectroscopic observation[7] showed the He II emission to have developed a P-Cygni profile, and emission at $\lambda\lambda$4,640–50 due to C III–N III was present. I report here the results of additional spectroscopic observations of this object.

Spectrograms were obtained on 1972 July 13.340, 1972 July 14.417 and 1973 July 9.367 UT with the 82-inch (207-cm) and 107-inch (272-cm) reflectors at McDonald Observatory. The first two spectra cover the wavelength region from $\lambda\lambda$4,400 to 6,700 at a dispersion of 210 Å mm^{-1}. The third spectrogram covers the wavelength region from $\lambda\lambda$3,800 to 5,700 at a dispersion of 115 Å mm^{-1}. Both 1972 spectra show the He II and C III–N III emission features and P-Cygni structure is evident in the helium line. The radial velocity of the He II emission is -400 km s^{-1} for both spectra. This same velocity was observed on a spectrogram obtained the previous year[7].

The spectrogram obtained in July 1973 shows a strong Ca II K line, indicating a spectral type of F5 or later. The strength of the Balmer absorption lines, however, indicates a spectral type of A5 or earlier. The C III–N III emission is no longer present. The He II emission line is present, but with no evidence of P-Cygni structure. The measured radial velocity of the He II feature is -390 km s^{-1}. It seems that Cyg X-2 no longer exhibits large radial velocity variations. It should be noted that Cyg X-2 was monitored photometrically in 1971 and 1972 and no rapid variability was seen (P. Vanden Bout, private communication). The above data and the report[8] of radio variability in Cyg X-2 suggest that further optical studies are sorely needed.

This research was partially supported by a NASA grant to P. A. Vanden Bout.

Tungus Event Revisited

THE suggestion of Jackson and Ryan[1] that a "mini" black hole was responsible for the Tungus Event of 1908 is both imaginative and intriguing. Unfortunately, this miniature, hypothetical object cannot account for all the important phenomena known to accompany the event. On the same night of the Tunguska Fall, and for several subsequent nights, the Tungus and adjacent regions experienced abnormally bright skies[2]. Inhabitants of the entire Northern Hemisphere recorded anomalous extinction of atmospheric light subsequent to the fall[2].

Investigation of the soil samples in the Tungus area revealed numerous small magnetic globules with high nickel content. Although the high nickel content affirms that the globules are of extraterrestrial origin, this information alone does not insure that they originated with the Tungus Event. Most soil samples collected at random over the globe will contain similar cosmic dust. The spatial pattern of the globules collected in the Tungus, however, shows that the cosmic dust most likely originated from a massive meteoritic body of dimensions vastly greater than a few Ångstroms. Furthermore, this body had a trajectory similar to that of the Tunguska meteorite[3]. In addition to the magnetic globules, field workers in the area found fused silicate-magnetite spherules near the Tunguska epicentre. This type of cosmic remnant has been found nowhere else in the world[4].

All these data support the hypotheses that the Tunguska Event was caused by a comet with a head composed of iron and silicate fragments cemented together by frozen volatiles. On contact with the Earth's atmosphere, the comet exploded, scattering dust and fragments over the landscape and into the atmosphere, leaving no significant crater.

Although other phenomena may possibly be invoked to account for the Tunguska meteorite, it seems that the black hole is eclipsed by a comet. Of course this discussion does not preclude the possibility that a black hole comprised the nucleus of the comet or that black holes frequently may be the agent's condensing the materials in such bodies.

Generalisation of Hubble's Law

RECENTLY, several new efforts to improve the upper bound on the possible rest mass (m_0) of the photon have been made[1-3]. The theoretical basis is provided by Proca's equations[1]

$$(\Box + \mu^2)A_K = (4\pi/c)J_K \tag{1}$$

where charge is assumed conserved and $\mu = m_0c/\hbar$. The bounds vary from 2×10^{-43} g to 3×10^{-56} g. As Yourgrau and Woodward[4] point out, however, a finite mass is implicit in a 'tired light' interpretation of the cosmological redshift. When equation (1) is combined with Hubble's law[5]

$$d\nu/dl = -H\nu/c \tag{2}$$

it yields $\mu = H/2c$ and hence $m_0 < 10^{-63}$ g. Here ν is the photon frequency, l the distance traversed and H is Hubble's constant. In view of this limit a direct demonstration of the existence of a finite photon rest mass does not seem practical at present.

Photon-photon interaction has been suggested[6-8] as the 'tired light' mechanism involved. Although this does imply a finite photon rest mass serious objections have been raised on both experimental[9] and theoretical[10,11] grounds.

A direct local laboratory measurement of a 'tired light' effect requires a precision of about 1 part in 10^{18} per light s. That is well beyond present capabilities. As we shall indicate, however, equation (2), when generalised, implies a corollary 'tired body' effect which may be observable in a local system.

To see this, one has only to multiply equation (2) by Planck's constant (h).

$$d(h\nu)/dl = d(h\nu/c)/(dl/c) = -H(h\nu/c) \tag{3}$$

This immediately expresses the change of both the momentum and the energy of the photon as it moves along its path. Both of these relations can be combined into the four-vector form which constitutes the generalised Hubble's law (see ref. 12; a restricted form of equation (4) is given here).

$$dP_K/d\tau = -HP_K \tag{4}$$

The space terms yield the loss of momentum per unit time and the fourth component the loss of energy per unit length. Thus it seems from equation (4) that a non-relativistic body moving with momentum $\bar{P}$ will experience a 'tired body' force.

$$\bar{F} = -H\bar{P} \tag{5}$$

Since bodies in linear motion present the same observational difficulties as does light we turn to rotational motion. From equation (5) we see that the rate of loss of angular momentum L in a rotating system is given by

$$\dot{\bar{L}} = -HL \tag{6}$$

As an application, we can take the Earth-Moon system. (the basis of fossil data we have shown that its angular mome tum has apparently been continually lost over the past 1.75×1 yr[13]. The total loss over this period is about 5% of the present value. Calculation of H from equation (6) gives a value of about 10^{-18} s^{-1} as compared to the latest reported value[14] of $1.3^{+0.8}_{-0.4}\times10^{-18}$ s^{-1}. Details of this calculation are given elsewhere[12].

BIOLOGICAL SCIENCES

Orthotopic Heart Transplantation in the Pig

THERE is only one report of orthotopic heart grafting in the pig[1]; the longest survivor lived for 11 d. Heart-lung bypass in this species has proved to be difficult[2,3]. Our previous studies of organ grafting in pigs made the study of the orthotopically grafted heart interesting to us.

Landrace or large white/landrace littermate pigs, of either sex, weighing 20 to 30 kg were used as donor and recipient. Anaesthesia was with halothane and endotracheal anaesthesia as described for liver allografting[4]. The animals breathed spontaneously until the chest was opened, when the lungs were ventilated mechanically.

With the recipient pig lying on its back, incisions 8 cm long were made in the right iliac fossa and in the neck along each side of the trachea. On the left side an intravenous (i.v.) infusion was set up in the subclavian vein. Arterial pressure, arterial blood gases and *p*H were monitored by a cannula in the transverse cervical artery and the central venous pressure was measured by a cannula in the internal jugular vein. Heparin (4,000 IU) was given i.v. and a size 18 FG Bardic venous catheter was inserted into the superior vena cava (SVC) through the right external jugular vein. A 3 mm Bentall arterial cannula was inserted into the arch of the aorta through the right common carotid artery. The inferior vena cava (IVC) was cannulated through the right common iliac vein extraperitoneally with a size 20 Bardic venous catheter. The arterial and venous cannulae were connected to the primed lines of the heart-lung bypass machine. Additional tubing was connected from the machine to a low pressure sucker and a left ventricular vent.

Pancuronium (6 mg) was given i.v. and mechanical ventilation was begun. The chest was opened by a median sternotomy. The right pleural cavity was opened, but an attempt was made to leave the left pleural cavity intact, although this was not always possible. A tape was passed around the SVC caudal to the azygos vein; a similar tape was passed around the IVC and both tapes were threaded through rubber tubing to form snares.

For the bypass, the priming volume was 1,300 ml made up of 300 ml of dextran 110 and 1 l of ACD porcine blood less than 24 h old. Added to the priming fluid were 0.5 g potassium chloride, 1 g ampicillin, 4,000 IU heparin, 10 ml sodium bicarbonate (8.4%) and 4 ml calcium chloride (10%). The venous lines passed to two cardiotomy bags from which blood was pumped by a Sarne pump through a heat exchanger and then into a Travenol membrane oxygenator, a filter and then by a second Sarne pump to the arterial line.

The donor pig was anaesthetised by the same technique as the recipient. It lay on its back on the operating table with its left chest rotated uppermost; 3,000 IU of heparin was given i.v. and 6 mg of pancuronium. The lungs were then mechanically ventilated. The abdomen was opened by a midline incision and the abdominal aorta cannulated and connected to an ACD blood collecting bag. Whilst the animal was exsanguinated, the chest was opened on the left side in the fifth interspace, the sternum was divided obliquely and the right chest opened in the fourth space. The pericardium was opened, and the heart removed by first dividing the aorta and pulmonary artery 2 cm from their origins and then dividing the pulmonary veins and venae cavae close to the heart. The heart was inserted into normal saline at 10° C.

For the insertion of the graft, partial bypass was commenced on the recipient. A vent was inserted into the apex of the left ventricle of the donor heart and secured with a catgut purse-string suture. The caval snares were secured and full bypass started. Lung ventilation was reduced to a minimum but not stopped. The aorta and pulmonary artery were clamped and the heart removed leaving most of the atria intact. The donor heart was now removed from saline and the aorta was anastomosed to that of the recipient with a running 4/0 silk suture. Air was expelled from the aorta and the clamp was removed from the recipient aorta and pulmonary artery permitting coronary perfusion. The coronary sinus effluent and blood from the cut hemiazygos vein were returned to the bypass reservoirs via the low pressure sucker. The donor atria and atrial septum were sutured to the recipient atria with running 3/0 mersilene sutures which included the recipient atrial appendages. The pulmonary arterial anastomosis was now completed with a 4/0 running suture and the caval snares were removed. If sinus rhythm had not by now returned spontaneously and there was coarse fibrillation, the heart was defibrillated with a DC shock of 15 joules. If the myocardial tone was poor, 1 ml of 1/10,000 adrenaline was injected into the aorta before defibrillation. The bypass flow was gradually reduced as the donor heart took over the circulation and normal lung ventilation was resumed. Incisions were made in the pericardium to prevent tamponade and a patch of pericardium taken from the donor was sutured to the recipient pericardium to allow for cardiac dilation. The left ventricular vent was clamped and removed after securing a purse-string suture around its site of entry.

Table 1 Pigs with Orthotopic Heart Grafts

Number	Survival	Cause of death if known
1	2 h	Pulmonary oedema
2	2 h	Haemorrhage
3	4 h	
4	2.5 h	
5	7 h	
6	8 h	
7	12 h	Hyperthermia
8	12 h	
9	12 h	
10	2.5 d	
11	5 d	Rejection
12	5 d	Rejection
13	6 d	Rejection
14	18 d	Rejection
15	4.5 months	Rejection
16	4 months	Alive

When bypass was stopped and blood loss was minimal, the heparin was reversed with protamine sulphate given i.v. and fresh donor blood was infused to maintain a central venous pressure (CVP) of 4 to 10 cm of saline. Dipyridamole (Persantin, 10 mg), deslanoside (Cedilanid, 0.4 mg), calcium gluconate (1 g) and sodium bicarbonate (20 mEq), were infused i.v., and if the blood pressure fell 0.5 mg isoprenaline was given. An Argyle chest drain was inserted by the right ninth interspace. If the left pleural cavity was opened, a similar drain was inserted on the left. The bypass cannulae were removed, the right iliac fossa and neck wounds were closed. The chest was closed with trans-sternal nylon interrupted sutures, continuous nylon to approximate the muscles and subcutaneous tissue and chromic gut for the skin.

The three cannulae on the left side of the neck were left in place for i.v. infusion and monitoring of the central venous pressure, arterial pressure, arterial blood gases and *p*H. The chest drain was connected to an underwater seal and anaesthesia was stopped when the effect of the pancuronium had worn off. The animal was sedated with Valium (5 mg) given intramuscularly. When breathing movements were judged to be adequate, mechanical ventilation was stopped, and once spontaneous ventilation seemed to be satisfactory the endotracheal tube was removed, the chest drain was joined to a Heimlich chest drain valve and the pig was placed in a warm bed of straw. The following day the chest drain was removed and the animal was given food and drink *ad libitum*. No immunosuppressive therapy was given.

Sixteen pigs survived the operation, but ten died within the early post-operative period. Six animals survived for between 5 d and 4½ months (Table 1). Five of these died with typical stigmata of rejection consisting of round cell infiltration of the myocardium, oedema and vasculitis. One animal was alive and well 4 months after the operation. Animals surviving after 1 week gained weight and seemed to be healthy until the rapid onset of cardiac failure resulting from rejection.

The technique described here was evolved after much trial and error. Long term survival after bypass with bubble oxygenators was not achieved. Their substitution by the Travenol membrane oxygenator seemed to be the chief factor in achieving success with the bypass. Cullum[1] has described the extreme sensitivity of the porcine heart to ischaemia and advocated completing the aortic anastomosis first to revascularise the myocardium as soon as possible. Using this technique the coronary sinus blood tends to obscure the atrial anastomosis and careful suction is required.

At the end of the operation care of the animal is critical, because the pig recovering from anaesthesia is very intolerant to an endotracheal tube. Once removed, we have not been successful with reintubation. Tachypnoea is marked in the first 24 h and resembles the neonatal respiratory distress syndrome. The loss of surfactant could be a contributory factor. It was hoped that retaining the left pleural cavity intact might reduce respiratory distress but there were long term survivors in animals in whom the left pleural cavity had been opened. Once the animals survived 24 h, recovery was rapid. The pigs resumed normal feeding and seemed to thrive. We were surprised at the long survival in some of our animals. From previous studies by Childe and Morris[5] and ourselves[6] on heterotopic porcine heart grafts, rapid rejection was anticipated and this was observed by Cullum with orthotopic porcine cardiac allografts. We have shown that littermate donor/recipient pigs identical for tissue types, and with negative mixed lymphocyte culture reactions, can tolerate renal allografts for many months[7]. As there is a 1 in 4 chance of tissue type identity between two littermates, it is possible that the long survivors described in this communication received hearts from matched donors. This would indicate that the pig reacts to heart or kidney allografts in a similar manner. Further studies are planned on tissue-typed pigs.

Genetics of Growth in Axenic Medium of the Cellular Slime Mould *Dictyostelium discoideum*

ALTHOUGH *Dictyostelium discoideum* is normally grown on bacteria[1,2], it is desirable for most biochemical studies to use strains grown in the absence of bacteria (axenically)[3]. Isolation of these strains is laborious, however; for this reason we have investigated the genetic basis of growth in axenic medium and have developed a method for inserting the chromosomes bearing the genes for axenic growth into other non-axenic strains. This is made possible by our finding that genes for axenic growth are located on only two of the seven linkage groups and that chromosomes can be readily exchanged between different strains. Using an improved version of the methods employing parasexuality previously reported[4,5], we have selected axenic resegregants carrying various markers from non-axenic strains.

There are two independently derived strains capable of growth in axenic medium that are commonly used: Ax-2 (ref. 6) (ATCC-24397; derived from strain Ax-1 (ref. 3)) and Ax-3 (ref. 7) (also called A3). Mutants of strain Ax-3 which are temperature sensitive for growth were isolated using a bromodeoxyuridine selection method (R. H. Kessin and P. C. Newell, unpublished results). Non-axenic temperature sensitive strains M28 and TS12 were obtained from Dr E. R. Katz (Division of Biological Sciences, SUNY, Stony Brook, New York, USA). A temperature sensitive strain (Ax-2g88) of Ax-2 was obtained from Drs E. Gingold and J. M. Ashworth (Department of Biochemistry, Leicester University, England).

Temperature sensitive haploid strains to be fused to form temperature resistant diploids were grown in association with *A. aerogenes* for approximately 48 h at 22° C. Cells were collected from pre-aggregation plates, washed in cold water, and two mutants containing non-identical temperature sensitive mutations were shaken in equal numbers (5×10^6 of each) in 1 ml of water, or in some cases potassium phosphate (20 mM, *p*H 6.0–7.5) in a Linbro tissue culture dish (FB-16-24-TC). Shaking was for 15–17 h at 22° C, 150 cycles min^{-1}; under these conditions amoebae form 'balls' of aggregated cells[2]. Controls were conducted in which each parent was incubated separately. After incubation the aggregated cells were separate by vortexing, counted with a haemocytometer, and spread wit *A. aerogenes* on agar plates at the restrictive temperatu (27° C) at 1×10^6 to 3×10^6 amoebae per Petri dish. Temperature resistant diploids were selected at a frequency of about 1 in 10^6 amoebae. Their ploidy was confirmed using genetic markers, spore size, and, in a number of cases, cytological study. Diploids were purified by clonal passage and their spores stored in silica gel at 4° C. It was possible to maintain these diploids by clonal passage; they had a stability similar to that reported by Katz and Sussman[4].

The method used to form diploids described here considerably facilitates parasexual genetics[4] since (1) relatively few cells are used; (2) large numbers of crosses can be done at one time in the Linbro tissue culture dish which has twenty-four wells; (3) the method is quick and simple as the cells are not placed on filters; (4) the medium used for fusion can be varied and many parameters can be tested concurrently; (5) it is possible to fuse not only two non-axenic strains (see Katz and Sussman[4]) but also axenic and non-axenic strains and two axenic strains; (6) aggregateless and other morphological mutants can be fused readily using this method.

Growth in axenic medium of strains Ax-2 and Ax-3 was found to be a recessive character since diploids heterozygous for axenic chromosomes (formed by fusion of an axenic and a non-axenic strain) were phenotypically not able to grow in axenic medium. Using this fact it was possible to select haploid axenic strains by placing diploids heterozygous for axenic genes at a low concentration (10^4–10^5 ml^{-1}) in axenic medium. After a lag of approximately a week, growth of haploids was usually observed. The haploid axenic strain X2 derived from the diploid of M28 and Ax-3tsg1 was selected in this way (Table 1). Haploid axenic strains were also selected using resistance to recessive drug resistance markers. For example X14 was selected on cycloheximide (500 μg ml^{-1}) from the cycloheximide-sensitive diploid of X9 and NP12 (Table 1).

Diploids homozygous for Ax-3 chromosomes have been isolated. These grow axenically, although subculture in axenic medium results in an ever increasing frequency of haploids until only rare diploid cells remain. This reduction in ploidy from diploid to haploid also occurs when these diploids are grown in association with bacteria without cloning. It has been reported previously that ploidy in the diploid strain H-1 changes from diploid to haploid in bacterial culture in the absence of cloning[8,9].

Diploids formed by fusing Ax-2 and Ax-3 haploids grew axenically. Three such independently isolated diploids have been studied; they showed similar growth characteristics in axenic medium to homozygous Ax-3 diploids. Detailed cytological studies on all of these diploids will be reported elsewhere. From these results it seems that the genes involved with growth in axenic medium in the independently isolated strains Ax-2[6]

Table 1 Resegregated Axenic Strains

Parental haploids	Haploid resegregant*	Growth in axenic medium	Growth at 27° C	Brown pigment production	Spore colour	Spore shape	Cycloheximide resistance (500 μg ml^{-1})	Acriflavin resistance (100 μg ml^{-1})	Colony morphology
M28		−	−	+		Round			
NP2		+	−	−		Elliptical			
	X2	+	−	+		Elliptical			
†X9		−	−	+	White		+		
‡NP12		+	−	−	Yellow		−		
	X14	+	+	+	Yellow		+		
NP29		−	−	+				−	Aberrant aggregation
NP12		+	−	−				+	Normal
	X17	+	+	+				+	Normal

+ Denotes the presence of the characteristic.
* Resegregated strains are called X1 . . . n.
† Strain X9 was selected from the diploid of M28 × NP14.
‡ NP14 and NP12 are acriflavin-resistant strains of TS12 and NP2 respectively; no mutagenesis was used in their isolation.
To aid clarity, characteristics which are identical in both parental strains have been omitted.

[illegible] Ax-3[7] may be identical, or at least that the recessive genes [illegible]ed are the same. We have no evidence yet whether in addition to recessive genes there are dominant genes involved with growth in axenic medium, or indeed how many genes there are. From analysis of segregant classes (to be published elsewhere) it seems, however, that only two linkage groups have genes required for growth in axenic medium. The point to be stressed here is that since ability to grow in axenic medium in strains Ax-2 and Ax-3 is probably not associated with five linkage groups, these linkage groups from non-axenic strains can be readily inserted into axenic strains. By forming appropriate diploids, properties such as cycloheximide resistance, round spore formation, and brown pigment formation have been incorporated into strain Ax-3.

While all of the strains used in these genetic studies are temperature sensitive for growth, it is possible, by using two strains whose temperature sensitive mutations are unlinked, to select temperature resistant (wild type) haploid segregants with various markers. Ax-3 sporulates very poorly at 27° C; this is a serious disadvantage for developmental studies where wild-type and temperature sensitive strains are to be compared. We have selected temperature resistant haploid axenic strains (Ax-3) which show improved sporulation at 27° C. For example, X14 (mentioned previously), Table 1; X17, selected on acriflavin (100 μg ml^{-1}) from the acriflavin sensitive diploid of NP29 and NP12 (Table 1).

Axenic strains grow more slowly on bacteria than non-axenic strains[6]. Some of our temperature sensitive haploid axenics grow very slowly on bacteria, but by selecting haploid axenics with some chromosomes from non-axenics, we have been able to obtain axenic strains with growth rates on bacteria that are much improved (for example, strain X2, Table 1).

While our primary aim is to develop genetic analysis so that factors involved with cell interaction in *D. discoideum* can be studied, strains that are well characterised both genetically and biochemically are necessary. We believe that using the methods discussed here, selection of such strains is facilitated.

We thank Drs E. R. Katz, E. Gingold, and J. M. Ashworth for their gifts of temperature sensitive strains of *D. discoideum.*

X-ray Studies of the Interaction of CO_2 with Human Deoxyhaemoglobin

In addition to transporting CO_2 indirectly by way of the alkaline Bohr effect, haemoglobin can interact directly with CO_2 to form carbamate residues:

$$RNH_2 + CO_2 \rightleftharpoons RNHCOO^- + H^+$$

This reaction of CO_2 with haemoglobin is oxygen-linked so that at constant *p*H more CO_2 is bound to deoxy- than to oxyhaemoglobin, and conversely the oxygen affinity of haemoglobin is decreased in the presence of CO_2 (refs 1 and 2). The studies of Kilmartin and Rossi-Bernardi[3,4] on horse haemoglobin specifically modified at the N terminal amino groups by reaction with cyanate showed that at constant *p*H CO_2 has no effect on the oxygen affinity of haemoglobin when all four α-amino groups are carbamylated, but that only part of the oxygen-linked effect is inhibited when the α-amino groups of only the α or only the β chains are blocked. This implies that the N-terminal amino groups are solely responsible for the oxygen-linked CO_2 interactions and that this effect is shared between the α and β chains. More recent experiments have confirmed these results for human haemoglobin[5].

The X-ray study described attempts to locate the binding of CO_2 to crystalline human deoxyhaemoglobin directly. Because of unpublished evidence (quoted in ref. 2) that concentrated phosphate solutions "affect the reactions of haemoglobin with CO_2", these experiments were carried out with deoxyhaemoglobin crystals[6] soaked in solutions of 70% 2-methyl-2,4-pentanediol (MPD) to remove the native high salt mother liquor. Two sets of 3.5 Å diffractometer data were collected, one on crystals soaked in 70% MPD+CO_2/bicarbonate buffer at *p*H 7.4 (the CO_2 pressure was 1 atm), and another on crystals soaked in 70% MPD+20 mM bis-Tris buffer at *p*H 7.4. Figure 1 shows the difference electron density, calculated by subtraction of the two sets of data and using the native (high salt) structure factor phases[7]. The expected carbamate group appears as a positive peak, about 3 Å in diameter, immediately adjacent to the α-amino group of the β chains. Next to this positive peak is a large negative peak, which indicates that the native electron density labelled X^- in Fig. 1 has been displaced by the newly formed carbamate ion. The same displacement of X^- was observed in the X-ray studies of 2,3-diphosphoglycerate (DPG)[8] and inositol hexaphosphate (IHP; my unpublished work) binding, corroborating the identification of X^- as an inorganic anion, probably phosphate or sulphate.

Binding of organic phosphates produced marked changes in the conformation of deoxy β subunits (ref. 8 and my unpublished work) but binding of CO_2 does not seem to affect them. No movements can be detected among the several basic groups in the neighbourhood of the α-amino groups that would indicate the formation of strong carbamate salt bridges. Instead, the carbamate ion seems to be taking the place of the inorganic anion, X^-, and simply reduces the high concentration of positive charge at the entrance to the central cavity of the haemoglobin tetramer. Similarly, the environment of glutamate 6β—the site of the mutation in sickle cell haemoglobin, haemoglobin S—is unaffected by carbamate formation. Therefore (like DPG[9,10]) CO_2 should promote sickling at low and medium oxygen saturation levels by stabilising the deoxy conformation, but (unlike DPG[8,10,11]) CO_2 may not influence the gelation of fully deoxygenated haemoglobin S since under these conditions CO_2 would alter neither the quaternary structure of the tetramer nor the tertiary structure of the β subunits. The CO_2 difference map shows no carbamate formation at the N termini of the α chains. The reasons for this are not clear.

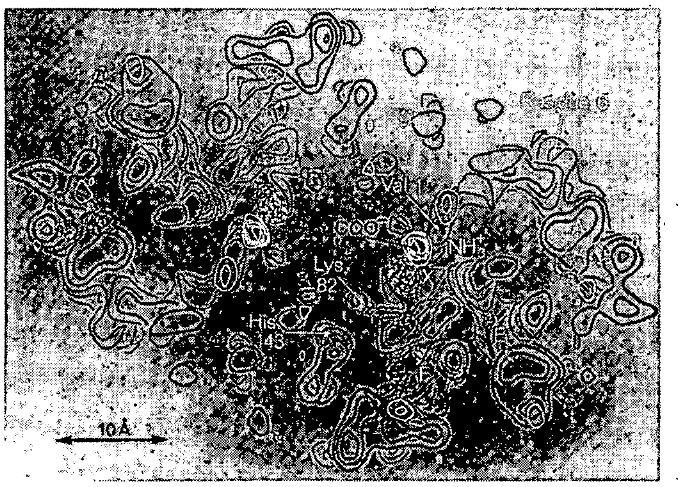

Fig. 1 Fourier map showing the reaction of CO_2 with the N-terminal amino groups of the β chains. Black contours: native human deoxyhaemoglobin electron density map at 3.5 Å resolution (9 sections, −15 to −23 Å). This region includes helices A, E and F and residues Val 1, Glu 6 (the site of the sickle cell mutation), Lys 82 and His 143 of each β chain. These features are related in pairs by the molecular two-fold axis of symmetry. The peak marked X^- has been identified as an inorganic anion (see text). The contours are drawn at intervals of 0.15 e Å^{-3} above the zero level. White contours: difference electron density due to CO_2 binding (3 sections, −18, −19 and −20 Å). Positive difference electron density is marked in solid white contours, negative difference electron density is marked in dashed white contours. The first difference contours are drawn at ±0.0091 e Å^{-3}, the next contours are at intervals of ±0.0045 e Å^{-3}.

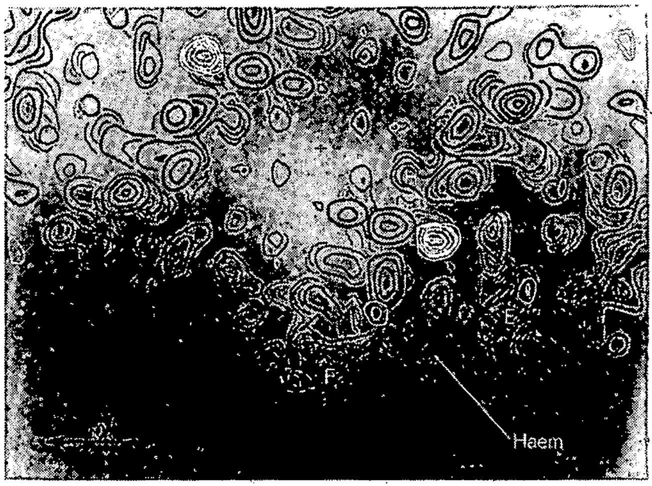

Fig. 2 Fourier map showing the binding of CO_2 to the region of the β-haem group. Black contours: native human deoxyhaemoglobin electron density map at 3.5 Å resolution (7 sections, −8 to −14 Å). This region includes parts of helices E, F and H. White contours: difference electron density due to CO_2 binding (2 sections, −8 and −9 Å) superimposed on th native protein density. Contour levels as in Fig. 1.

There is an unexpected positive difference peak the β haem group (Fig. 2). The atomic model o haemoglobin shows this strong positive peak to be em dded in the centre of a highly hydrophobic hole. The dimensions of the peak are consistent with the binding of CO_2 or HCO_3^-, but the hydrophobic nature of the binding site favours the neutral CO_2 molecule. Since physiological CO_2 pressures do not affect the oxygen affinity of cyanate-blocked haemoglobin[3-5], and I have used nearly twenty times the physiological pressure, the binding of CO_2 at this site may be insignificant at these pressures (40 to 50 mm Hg). If it is significant it should not be oxygen-linked; however, it should be remembered that gases do form non-covalent complexes with haemoglobin[12], and that xenon binds to both the α and β chains at specific hydrophobic sites formed by the A–B and G–H corners[13].

In summary, this X-ray study confirms that CO_2 reacts with the N-terminal amino groups of the β chains to form carbamate ions. It also shows that this reaction displaces an inorganic anion normally bound to the β chain α amino group, but does not cause significant changes in the tertiary structure of the deoxy β subunits. The conditions used in this study of high CO_2 pressure and a low salt MPD environment may, however, have exaggerated a minor effect—the binding of CO_2 in a hydrophobic hole to the rear of the β haem group—and inhibited a major effect—the reaction of CO_2 with the N terminal amino groups of the α chain.

I thank Dr M. F. Perutz for suggesting this experiment, Dr J. V. Kilmartin and Dr L. Rossi-Bernardi for discussions, and the US National Institutes of Health for a fellowship.

Cell Shape Regulation and Cell Cycle in Embryonic Lens Cells

EYE lens development in the chicken embryo begins with transformation of the ectoderm destined to become lens from a low cuboidal to a high columnar epithelium. Simultaneously the nuclei pass to the basal poles of the cells. This 'palisading'[1] gives the lens anlage a regular appearance, but individual cells may deviate considerably from he columnar shape, largely because of their replicative ehaviour.

All presumptive lens cells are dividing asynchronously at this stage[2] and show interkinetic nuclear migration[3]. This phenomenon, first described by Sauer[4], has been studied extensively in the neural tube, but occurs in many embryonic epithelia. Cells are anchored at their free apical surfaces by intercellular complexes and contract toward this surface for mitosis. Afterwards, during G_1, they elongate again and their nuclei are displaced toward the basal parts of the cells, where DNA synthesis is initiated. At the end of the S phase the nuclei take the reverse route; cells round up again and a new round of mitosis begins. The position and size of the nucleus therefore can be used to classify cells morphologically according to cell cycle phase (our report in preparation). We describe here that the latter is correlated with the surface to volume ratio of the cells and suggest that cell volume regulation may play a role in cell shaping.

White Leghorn chicken embryos, incubated for 48–55 h, were fixed in glutaraldehyde and osmium tetroxide and embedded in Araldite by routine methods. Frontal sections were cut serially at 0.5 μm and stained with toluidine blue. Invaginating rudiments (stages 14 and 15 according to O'Rahilly and Meyer[5]) were selected and from photomicrographs serial tracings were made of lens cells and nuclei. From planimetric measurements we calculated for each cell the distance from the centre of the nucleus to the basement membrane, nuclear volume, cellular surface area and volume, and cell surface to volume ratio.

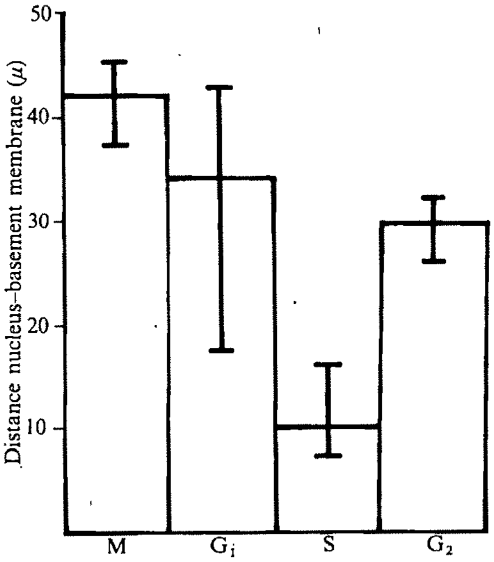

Fig. 1 Histogram indicating the extent of nuclear migration during the replication cycle of cells of the invaginating lens cup. For cells in mitosis the centre of the cell was assumed to correspond with the centre of the nucleus. The vertical bars in this and the following figures indicate the actual range of values; the columns represent the averages of the measurements.

Figure 1 shows that the nuclei migrate up and down more than 40 μm when the tissue is approximately 50 μm tall. When the nuclear membrane reforms after mitosis the nuclear volume is about 70 μm^3. It increases to four times as much for the average G_2 cell. In general, nuclei take up more than a third of the cellular volume during interphase (compare Figs 2 and 4).

Measurements of the cellular surfaces show that the average surface area in G_1 is about half that of mitotic cells. The area then increases with the progression of the cell through the cell cycle, but as the cell approaches division and contracts toward the free tissue surface again, the increase slows down and there may even be a slight decrease of surface area (Fig. 3). The changes in cell volume as a function of cell cycle phase show some intriguing differences from the surface changes. Most notably, the value for the G_1 cell is substantially less than the expected half of the mitotic cell volume (Fig. 4). Cell volume then increases, more or less parallel to the surface area curve, but at the end of the cell cycle when the cell approaches division the volume continues to increase instead of diminishing as the surface area does, and the mitotic cell is on average considerably larger than the G_2 cell. As a result, the surface to volume ratio is smallest during mitosis and largest in G_1, with a gradual decrease during S and G_2 (Fig. 5).

We believe that these observations are germane to an understanding of the structural changes of presumptive lens cells in relation to the cell cycle as well as the developmental stage. The decreasing surface to volume ratio in G_2 indicates that the volume increase outpaces the growth of the surface, suggesting the generation of membrane tensile stresses. Entry into mitosis is accompanied by a further substantial increase in cell volume and a slight decrease in surface area. A sphere has the smallest surface to volume ratio of all possible configurations of a given volume and, moreover, this ratio diminishes with increasing size. Geometry makes it tempting, therefore, to postulate that volume increase

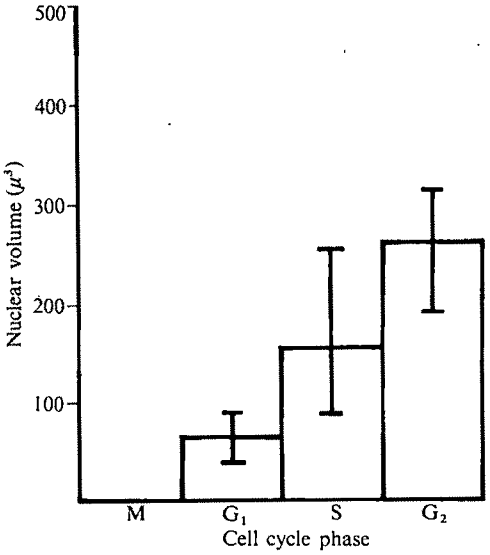

Fig. 2 Cell nuclei become larger with the progression of the cell cycle. Obviously, during division the nuclear membrane has become dissociated and the nuclear volume cannot be measured. Nuclear volumes were determined in the same way as cellular volumes (Fig. 4).

forces the cell to round up in preparation for mitosis. The very rapid change in volume may be due to an influx of fluid from the cellular environment, an explanation compatible with the low density of the mitotic cell, as judged from staining characteristics. These interpretations agree with earlier results: it is well known that cleavage of sea urchin eggs is accompanied by increase of tension in the cell membrane[6], and L cells in culture show appreciable increases in volume and decreases in surface to volume ratio when division begins[7].

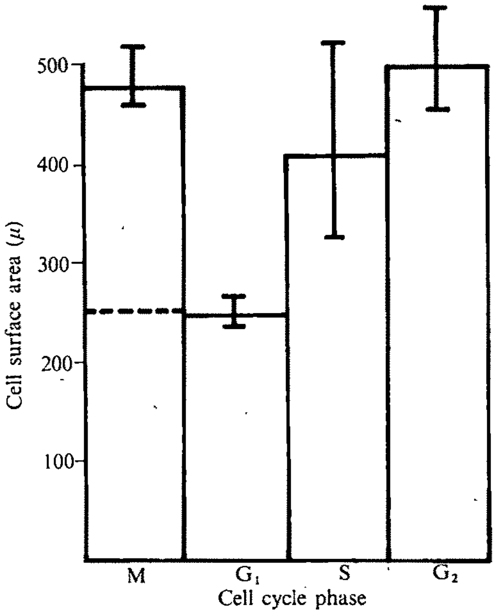

Fig. 3 The average cell surface as a function of cell cycle phase. The surface of each cell was calculated by summating all measured outlines of the cell in serial photomicrographs and taking into account the magnification factor and the thickness of the sections. Electron microscopy indicates that the surface of lens cells at this stage is very regular. Therefore, the outline of the cell at the light microscopic level does in fact represent its surface. Note that the average surface area of the G_1 cell is about the same as half the surface of the mitotic cell (broken line in first column). The surface area becomes larger with the progression of the cell cycle, but appears to diminish somewhat at the end, with the transition from G_2 into M.

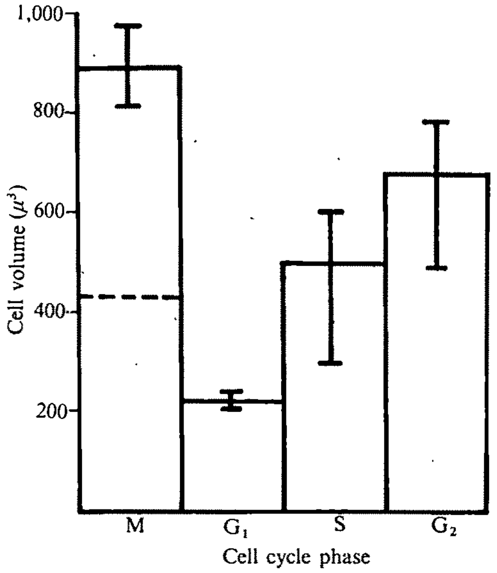

Fig. 4 Cell volume in relation to the cell cycle. The volume was calculated by planimetrically determining the surface of each section through a cell from serial photomicrographs, summating all the areas, and taking into account the magnification and the section thickness. In striking contrast with the surface area changes (Fig. 3) the G_1 cell volume is much smaller than that of the halved mitotic cell. The volume increases continuously over the cell cycle, and the dividing cell is clearly larger than the G_2 cell.

With the transition from mitosis to G_1, the opposite occurs. The division of a sphere into two smaller spheres requires more surface area, relative to the same total volume. This requirement increases when the cell elongates in G_1. Theoretically, the cell can only attain this change in structure by increasing its surface or decreasing its volume. Apparently the latter is favoured in this system, the average G_1 cell volume being considerably less than the expected half of the mitotic cell volume. Because G_1 cells stain very intensely we believe that loss of cytoplasmic fluid may be involved. Whether active transport phenomena are responsible remains to be determined.

Lens placode formation is characterised by cellular elongation and it seemed possible that the extent of the latter is regulated by controlling the volume, apparently lost by the post-mitotic cell. Preliminary work indicates that this is not the case. Throughout early lens development the changes in cell volume and surface in relation to the cell cycle are comparable with those described here for the invaginating rudiment. Thus, we hypothesise that the high surface to volume ratio of the G_1 cells allows it to assume various shapes, including the columnar one. Conversely, the diminishing of the ratio in G_2 limits this freedom and pushes the cell towards a spherical form. Cell volume decrease in G_1 permits the cell to elongate, but it does not instruct it to do so; other forces must cause the elongated shape to be favoured[8].

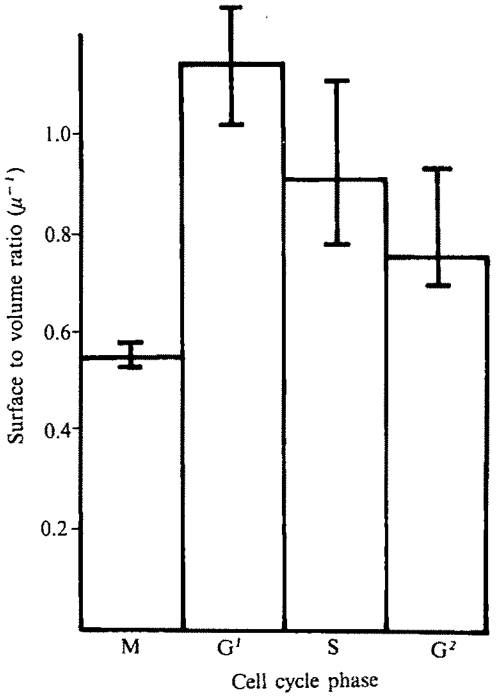

Fig. 5 The surface to volume ratio decreases from high values for G_1 to the lowest ones for mitotic cells, indicative of a progressive limitation of the theoretical freedom that the cell has to assume various morphological configurations. Geometric laws dictate that a structure with a high surface to volume ratio can have any number of shapes, while a low ratio has to be associated with a spheroid form.

Our observations indicate that regulation of cell volume may well delineate the options open to a cell in the determination of its shape. Except for Cone's work[7], this aspect has received little attention. If the volume adjustments found here turn out to involve active transport mechanisms, as we suspect, the associated osmotic changes may well be important in the control of mitosis[7] and DNA synthesis[8]. Our methodology should be applicable to other systems to facilitate classification of cells according to cell cycle phase without reference to synchronisation and (or) isolation of cell populations.

Precursor 16S RNA in Active 30S Ribosomes

BIOGENESIS of bacterial ribosomes proceeds through the formation of precursor particles[1–4], consisting of an incomplete set of ribosomal protein[5] and of RNA molecules that are longer and less methylated than mature RNA[4,6,7]. RNA maturation is commonly considered to be a part of the ribosome maturation process. Here we report that newly formed 30S ribosomes can enter polyribosomes while they still contain precursor RNA. Maturation of ribosomal RNA might be completed not before, but after, ribosomes have interacted with messenger RNA.

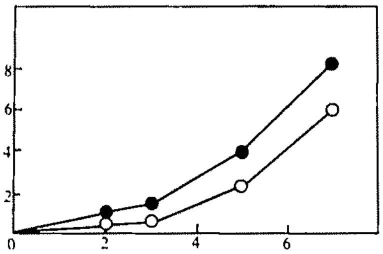

Fig. 1 ^{3}H-uracil uptake in m16S RNA and 30S particles. A culture of *Escherichia coli* D10 in medium MS9 (ref. 9) supplemented with 0.5% casa-amino acids (doubling time 32 min) was labelled with ^{14}C-uracil (0.1 μC ml^{-1}). After two generations, ^{3}H-uracil was added (5 μC ml^{-1}). At indicated times, samples were rapidly chilled and lysed as previously described[10]. A portion of each lysate was centrifuged through a 10% to 30% sucrose gradient in 10^{-4} M MgCl$_2$, 10^{-2} M Tris-HCl, *p*H 7.8, at 40,000 r.p.m. for 8 h to display 30S ribosomes and precursor particles. The peak fraction of the 30S region of each gradient was diluted with three volumes of 10^{-4} M MgCl$_2$ and centrifuged through a second sucrose gradient to resolve 30S ribosomes from precursor particles completely. The ratios of ^{3}H to ^{14}C counts in 30S ribosomes are plotted against labelling time (●—●). Another portion of each lysate was treated with phenol and sodium dodecyl sulphate to extract the RNA. After ethanol precipitation, the RNA was electrophoresed for 6 h at 5 mA per tube on 3.6% polyacrylamide gels prepared as previously described[10]. The ^{3}H to ^{14}C ratios in m16S RNA were multiplied by a factor 1.5 and then plotted against time (○—○). This correction was necessary to obtain comparison with 30S ribosome ratios, since different conditions were used for counting sucrose gradient and gel fractions. ^{3}H and ^{14}C counting efficiency was controlled for each experiment by including an extra gradient with 30S ribosomes uniformly labelled with ^{3}H and ^{14}C uracil, and an extra gel with 16S RNA extracted from the same 30S particles.

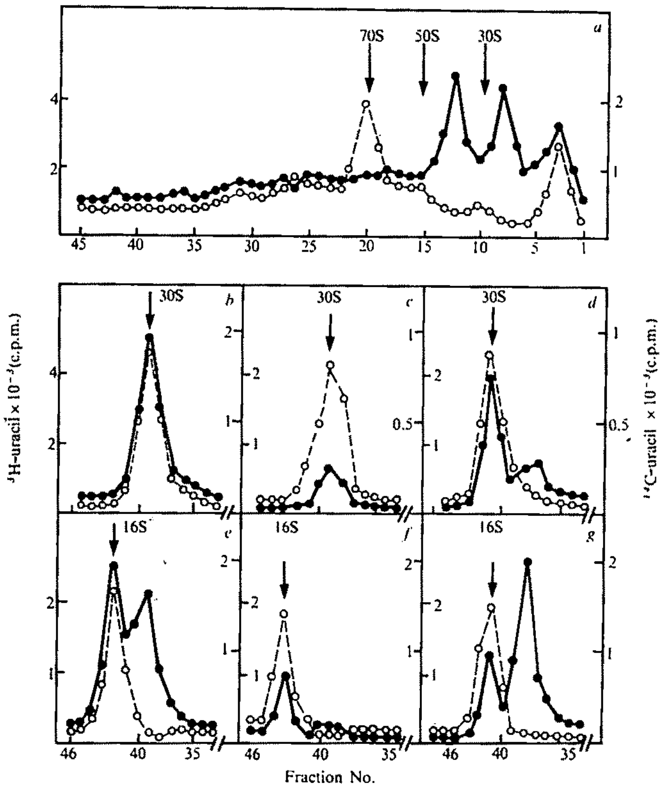

Fig. 2 Newly formed RNA in native and derived 30S subunits. *a*, A lysate of cells labelled with ^{14}C-uracil for two generations and with ^{3}H-uracil for 3 min, as in Fig. 1, was centrifuged on a sucrose gradient in 10^{-2} M MgCl$_2$, 10^{-2} M Tris-HCl, *p*H 7.8, for 2 h at 40,000 r.p.m. to display free and messenger-bound ribosomes. Fractions 25–42 were pooled and dialysed at 2° C against 10^{-4} M MgCl$_2$, 10^{-2} M Tris-HCl, *p*H 7.8. Ribosomal subunits were collected by centrifugation and resuspended in 0.5 ml of the dialysis buffer. This sample, as well as fractions 20 and 10 of the original gradient, were centrifuged on three parallel gradients in 10^{-4} M MgCl$_2$ for 8 h at 40,000 r.p.m. to display 30S subunits. *b*, 30S derived from polyribosomes (fractions 25–42 of *a*); *c*, 30S derived from 70S (fraction 20); *d*, native 30S (from fraction 10). From the peak fraction of each of these three gradients RNA was extracted and analysed by gel electrophoresis as in Fig. 1. *e*, RNA from polyribosomal 30S; *f*, RNA from 30S derived from 70S; *g*, RNA from native 30S. The top of gradients and of gels is at the right. ●, ^{3}H-uracil c.p.m.; ○, ^{14}C-uracil c.p.m.

As we have briefly noted elsewhere[8], conversion of 17S and 16.5S RNA (p16S) into mature 16S RNA (m16S) does not occur at the same time as that of precursor particles into 30S ribosomes. In the experiment summarised in Fig. 1, we have followed the entry of ^{3}H-uracil into m16S RNA and 30S particles during continuous labelling. A delay of 1 to 2 min in m16S RNA labelling was found by comparison with 30S particles.

This suggested that newly formed RNA is incorporated in particles sedimenting as 30S while it is still immature. These particles might be precursors not resolved from mature ribosomes on sucrose gradient, like those recently described by Lindahl[11]. When we examined the distribution of newly synthesised RNA in various ribosomal fractions we found, however, that p16S was present not only in native 30S ribosomes[12], but also in 30S subunits derived from polyribosomes (Fig. 2). The ratio between mature and immature RNA was

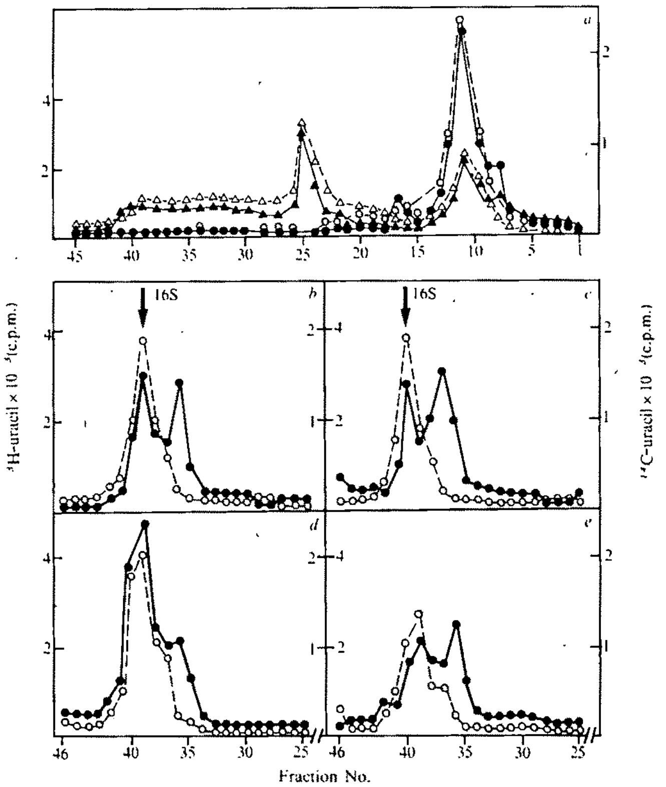

Fig. 3 Formation *in vitro* of polyribosomes from native subunits and T4 RNA. Native 30S particles were isolated by sucrose gradient from a lysate of cells prelabelled with ^{14}C-uracil and labelled with ^{3}H-uracil for 3 min. The labelled particles were mixed with a crude extract (S30) prepared from unlabelled cells, and incubated in conditions of protein synthesis with or without T4 RNA[10]. S30 had been preincubated at 37° C for 10 min. After 2 min of incubation chloramphenicol was added (200 μg ml^{-1}) and the mixture was centrifuged on a sucrose gradient in 8 mM $MgCl_2$, 10 mM Tris-HCl, *p*H 7.8, for 2 h at 40,000 r.p.m. *a*, Gradient distribution of 30S incubated for 2 min with (▲, ^{3}H; △, ^{14}C) and without (●, ^{3}H; ○, ^{14}C) T4 RNA. RNA was extracted from fractions 26–40 and from fraction 10 of the first of the two gradients. *b* and *c* show the gel analysis of these two preparations of RNA, in that order. The top of gels is at the right. The same analysis was made on 30S ribosomes incubated with T4 RNA for 4 min. The gradient is not shown. In *d* and *e*, gel patterns are given for RNA extracted from polyribosomes and free 30S.

different in the two fractions. After 3 min of labelling, native 30S particles contained most of their ^{3}H label as p16S RNA; 30S derived from polyribosomes contained half of their ^{3}H label as p16S and half as m16S RNA. 30S subunits derived from 70S monosomes contained only 16S RNA, Later the portion of ^{3}H label increased in all fractions.

These results indicate that immature RNA can be incorporated in particles that not only sediment as 30S, but can also enter polyribosomes. The relationship between ribosomal subunits found free in a cell extract and those in polyribosomes and 70S monosomes is not yet completely clear[13]. The ratio of immature to mature RNA in these fractions is, however, consistent with the hypothesis that newly formed 30S ribosomes enter polyribosomes while they still carry p16S RNA and are released after the RNA is converted to m16S. Maturation of the RNA would then occur in polyribosomes.

This interpretation is supported by *in vitro* experiments in which native 30S particles were tested for their ability to respond to natural messenger RNA. Labelled 30S ribosomes were added to a cell crude extract and incubated in conditions of protein synthesis (Fig. 3). In the presence of T4 phage specific RNA, newly formed ^{3}H-labelled 30S particles formed 70S and polyribosomes with the same efficiency as the pre-existing ^{14}C-labelled 30S. After the first 2 min of incubation *in vitro*, the ^{3}H label that had entered polyribosomes was distributed between m16S and p16S RNA in the same proportion as in free 30S particles. After 4 min, the ^{3}H fraction in m16S was higher in polyribosomes than in free subunits. In the absence of T4 RNA, no formation of polyribosomes and no conversion of p16S into m16S RNA were observed under the same conditions. These data confirm that 30S particles containing p16S RNA can enter polyribosomes, and once again suggest that maturation of the RNA occurs preferentially in polyribosomes.

We were unable to test whether the particles containing p16S RNA are fully competent in protein synthesis because we could not separate them from those containing m16S RNA. For the same reason, we could not determine their protein content. Furthermore p16S RNA was identified by gel electrophoresis, but was not characterised further. Therefore the possibility that RNA maturation plays a role in the structural or functional maturation of ribosomes cannot be excluded.

The data presented here, however, suggest an additional possibility, namely that complete RNA maturation may n be required to make a ribosome functional. On the contrar the functioning of a ribosome may be necessary for its RNA to mature. A conformational change of the particle, for example, may be required to expose the RNA to a nuclease attack. In this case splitting of the extra nucleotide sequences from the immature RNA molecules would occur at a rate determined by the chance which newly formed ribosomes had of entering polyribosomes, and therefore could serve to signal how many new ribosomes are needed.

We thank Professor G. Filogamo for advice and support and Dr D. Hayes for discussions. This work was financed by Italian Consiglio Nazionale delle Ricerche and North Atlantic Treaty Organisation grants to G. M.

Antibody-dependent Killing of *Cryptococcus neoformans* by Human Peripheral Blood Mononuclear Cells

CRYPTOCOCCOSIS is a systemic fungus infection caused by the encapsulated yeast-like fungus, *Cryptococcus neoformans*. It has been suggested that alterations in cellular host defence mechanisms increase susceptibility to infection with this organism[1,2]. *In vitro* studies suggest that human peripheral blood neutrophils and monocytes can ingest and kill cryptococci[3,4]. There is, however, a wide range of killing in cells from different normal subjects (21–89%), and no apparent defect in cells from patients with cryptococcosis[3]. This makes it unlikely that peripheral blood neutrophils or monocytes play a decisive role in determining susceptibility to cryptococcosis in individual patients. In other *in vitro* studies, activated macrophages derived from human peripheral blood monocytes not only failed to kill cryptococci, but provided a preferentially favourable medium for intracellular growth of the fungus[5]. These studies, as well as the known histopathology of cryptococcal lesions, suggest that many of the organisms, particularly large capsule forms, are extracellular and so not subject to the intracellular killing mechanisms of phagocytes. Anti-cryptococcal antibody, with or without complement, does not kill cryptococci in the absence of leukocytes[3]. I therefore investigated the possible existence of a non-phagocytic cellular killing mechanism.

Mononuclear cells were separated from heparinised human peripheral blood from normal donors as outlined by Böyum[6]. Final preparations consisted of 20–38% monocytes (by neutral red ingestion), plus 62–80% lymphoid cells of other types. A small capsule isolate of *Cryptococcus neoformans* was cultured 72 h on Sabouraud's agar and washed as previously described[3]. Anti-cryptococcal antibody was raised in rabbits and standardised by slide agglutination as outlined by Wilson *et al.*[7]. The agglutination titre of serum used in these studies was 1 : 512. Control serum was obtained from the same rabbit before development of antibody.

If phagocytosis is blocked, it seems that mononuclear cells can readily kill cryptococci only if anti-cryptococcal antibody is present. Maximum killing was noted after 24 h incubation (Table 1). At 4 h, 45.5% of the original inoculum survived. Beyond 24 h, results were difficult to interpret because of variable growth of remaining fungi. Microscopic examination confirmed that clumping of organisms could not explain the apparent killing which was observed. Similarly, little or no phagocytosis of organisms was noted, as expected in a system nearly free of serum. But the high ratio of leukocytes to fungi in this system allowed the possibility that a small amount of phagocytosis might be missed, yet still result in significant killing. Therefore, incubations were performed with 10 μg ml^{-1} cytochalasin B, which completely inhibited phagocytosis of cryptococci. Others have noted that this concentration does not block antibody-dependent cell-mediated cytotoxicity[8], and only partially blocks cytotoxicity by immune spleen cells if cells are mixed to facilitate contact[9]. In three paired experiments, killing as reflected by percentage survival of the original inoculum was not significantly changed at 24 h in incubations containing cytochalasin B (mean ± s.e. of the mean survival 5.3 ± 5.3%, changed to 9.2 ± 6.9% with cytochalasin B).

Further dilution of antibody to 1 : 20,000 did not reduce killing (6.6% survival), but at 1 : 200,000 dilution, 73.3% of the original inoculum survived at 24 h. The optimum ratio was 50–100 leukocytes per cryptococcus. At a 20 : 1 ratio, 72.8% of the original inoculum survived, increasing to 88.0% at a 5 : 1 ratio. No killing was observed at 1 : 1 ratio (100% survival).

Preliminary studies indicated that human antibody can act in this system. Serum obtained from a patient with cryptococcosis was found to contain anti-cryptococcal antibody by an indirect fluorescent antibody technique[10]. When incubated in a 10% final concentration with mononuclear cells from two normal donors plus 10 μg ml^{-1} cytochalasin B to block phagocytosis, only 7.3% and 28.1% of the original cryptococcal inoculum survived at 24 h. In another experiment, normal serum was used which had no detectable anti-cryptococcal antibody by the indirect fluorescent antibody technique, but did have antibody present by a more sensitive absorption technique[11]. The IgG fraction from this serum was separated by the DEAE batch technique of Stanworth[12]. When 11 mg ml^{-1} was added to incubations, only 29.2% of the original cryptococcal inoculum survived at 24 h.

Table 1 Effect of Anti-cryptococcal Antibody on Survival of Cryptococci cultured with and without Mononuclear Cells

Leukocytes present*	Antibody present†	Survival of original cryptococcal inoculum (% at 24 h‡)
Yes	Yes	(6.8 ± 3.2)
Yes	No	(111.3 ± 7.6)
No	Yes	(158.0 ± 43.0)
No	No	(186.8 ± 49.0)

* 50–100 leukocytes : 1 cryptococcus.

† 1 : 2,000 dilution of hyperimmune serum or serum from the same rabbit obtained before development of antibody.

‡ Mean ± s.e. of the mean of experiments using leukocytes from nine donors. Original inoculum represented as 100%.

Triplicate 35 mm plastic dishes each contained approximately 5×10^4 cryptococci quantified by plate counts, with or without varying ratios of leukocytes in 1 ml of medium. Media consisted of heated (56° C for 30 min) rabbit serum diluted 1 : 2,000 or greater with Eagle's minimal essential medium enriched as outlined elsewhere[20]. Dishes were incubated at 37° C in 5% CO_2 with continuous mixing on a rocker platform for 24 h. Leukocytes were lysed and clumps dispersed using Triton X-100 in saline (1 : 1,000 final dilution when added to culture dishes). Dishes were scraped with a rubber policeman and washed four times with Triton X-100 into a test tube which was vigorously mixed. This treatment did not decrease viability of cryptococci. Further tube dilutions were performed in distilled water. Live organisms were quantified by plate counts and the number compared with the original inoculum to measure any growth or killing which occurred during the period of incubation.

Separated mononuclear cells suspended in 10 ml of medium were incubated in 100 × 20 ml plastic dishes on rocking platforms at 37° C for 30 min in 5% CO_2. Non-adherent cells were removed and the procedure was repeated twice. When these non-adherent cells were used in incubations, killing was reduced 60% compared with incubations where adherent cells were not removed. This suggests that the killer cells in this system have some capacity to adhere to surfaces. If this system is analogous to antibody-dependent cell-mediated lysis of erythrocytes or other target cells as described by several workers[13–17], my results are consistent with those reported by Van Boxel using mouse spleen effector cells[17]. Studies are in progress to identify the specific effector cell which can kill cryptococci. Because of the heterogeneous nature of the mononuclear cell population used in this system, the possible roles of monocyte-like cells[18], B lymphocytes[17], or other cells is still uncertain.

In any case, it seems that mononuclear cells in the presence of specific antibody can kill a microorganism, *C. neoformans*, by a non-phagocytic mechanism. The relevance of these observations to *in vivo* conditions remains to be established. It may, however, be noteworthy that the presence of anti-cryptococcal antibody in the serum of patients with cryptococcosis has been correlated with eventual cure[10]. Antibody-dependent cell-mediated killing as well as other cellular non-phagocytic killing mechanisms[19] may well be important in dealing with microorganisms which are not readily ingested by phagocytic cells.

I thank Drs J. E. Bennett, H. R. Kimball, J. A. Van Boxel and A. C. Allison for suggestions, and A. S. Rosenthal for supplying cytochalasin B.

Mechanism of Action of Dental Electro-anaesthesia

NEWMAN[1] has proposed that the analgesia produced by passing a small electric current from the dental drill (positive) to a hand electrode (negative) is due to anodal blocking of nerve fibres within the tooth. Fields *et al.*[2] feel that the likely mechanism is electrocoagulation of odontoblasts in the dentinal tubules under the site of drilling. The difference is clinically important, for anodal blocking is a harmless reversible process whereas the destruction of odontoblasts leaves permanent dead tracts in the dentin under the site of application of the current. These two mechanisms can be separated by applying stimulation and electro-analgesic current to different sites on the same tooth, since the local mechanism (electrocoagulation) would have no effect in blocking a stimulus applied elsewhere.

Ten cats were prepared with chronic amalgam implants on the upper canine teeth[3,4]. Eight of these had two-electrode implants; two were prepared with three-electrode implants. The stimulating, anaesthetising, and recording arrangements were as shown in Fig. 1. Current was applied from an implant close to the apex of the pulp chamber, with a return lead from a stainless steel screw embedded in the skull, simulating normal dental electro-analgesic practice. Test stimuli were applied from another tooth implant to the skull (Fig. 1*A*), or between two other tooth implants (Fig. 1*B*). The jaw opening reflex[3,4], monitored electromyographically, was used as the index of pulp excitation. The cats were tested repeatedly at intervals over a period of 3 to 4 months. All were awake; the test stimulus used does not induce overt distress or escape behaviour in the cat provided the pulse is brief, mild and not too frequent[4,5].

Typical results are shown in Fig. 2. Anodal current reduced or blocked the reflex response; cathodal current increased it. The smallest effective current was 20 μA, and typically 40 to 60 μA was required for a full block. The blocking tended to be cumulative, in the sense that successive blocks required less current. There was, however, complete recovery between sessions.

In a few trials, much larger currents (500 to 2,000 μA) were used for comparison with the practice of ionic desensitisation[6,7], which is known to produce local damage to odontoblasts. On cessation of this blocking current, the cats tested were visibly distressed and drank copiously; there were no obvious permanent after effects.

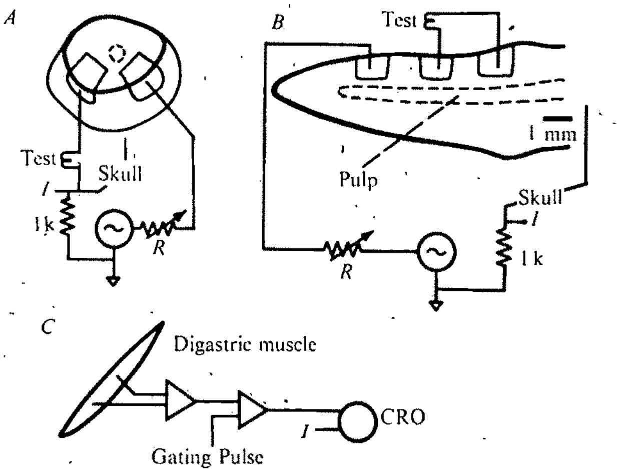

Fig. 1 Three-terminal (*A*, eight cats) and four-terminal (*B*, two cats) arrangements used for testing anodal blocking of pulp nerves. The test pulse was 0.2 ms long, 200 to 500 μA in amplitude, derived from an r.f.-isolated bipolar source which had an internal resistance of 100 kΩ. In arrangement *A* the polarising and test currents both passed through the tooth root to the skull; in *B* the test pulse was confined within the tooth. Point *I* was connected to the lower beam of the oscilloscope to record current passed through the polarising electrode. The signal generator was operated at constant voltage (centre zero, range ±10 V) and the polarising current was varied by changing *R* within the range 0.1 to 1.0 MΩ. The digastric EMG was monitored as shown in *C*. Hook electrodes, of platinum or nichrome wire, 1 cm long and 0.25 mm diameter, were chronically implanted about 1 cm apart in each digastric muscle. Leads from a skull plug were run to a differential preamplifier of gain 100, bandwidth 80 Hz to 10 KHz, input impedance 10 MΩ. The output from this amplifier went to a gated amplifier which displayed, on the upper beam of the oscilloscope, the segment of EMG waveform occurring 4 to 13 ms after each test stimulus (see Fig. 2).

The currents found adequate to block the jaw opening reflex in this study are comparable in magnitude with those effective in clinical electro-analgesia[1,2,8]. The site of testing is separated from the site of injection of the polarising current, so the block of response cannot be due to an inactivation of receptors in the dentin under the polarising electrode. The reversible blocking seen is consistent with the known properties of anodal blocks on other nerves[9]. Thus, it seems that anodal polarisation of pulp nerves may be a significant mechanism in the clinical relief of tooth pain. These findings do not exclude the possibility that local damage to odontoblasts may also play a role. [illegible]ars of clinically significant damage produced by curre[illegible] of 60 μA or less are, however, probably unwarranted, since much larger currents have been used routinely for dentin

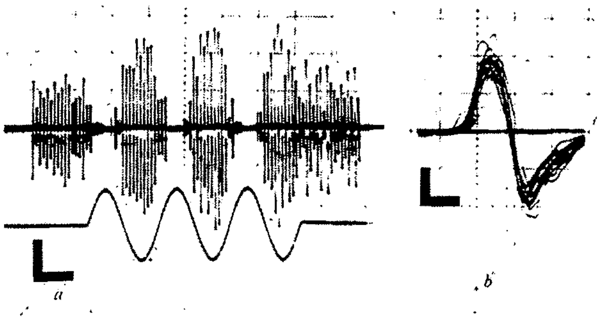

Fig. 2 *a*, Variation of digastric EMG amplitude with polarising current. Each vertical line on the upper trace is a 9 ms segment beginning 4 ms after a test stimulus to the tooth. Test stimuli are applied at a rate of 2 s^{-1}. Calibration: upper trace, 2 mV; lower trace, 20 mV (equivalent to 20 μA); time, 5 s. Lower trace shows the polarising current applied; tooth positive (anodal) is up. *b*, Detail of EMG waveform. Ten sweeps with stimulus, five without. Calibration: 2 mV; time, 2 ms. Only the gated portion of the response is shown.

desensitisation for many years[6,7].

I thank Mr L. Henderson, who prepared the amalgam implants for this study, and the National Institute of Dental Research for financial support.

Variation with Sex of Irradiation-induced Chromosome Damage in Somatic Cells of *Drosophila melanogaster*

IN *Drosophila melanogaster*, much information has been collected on chromosome mutations analysed by genetic methods, but there has so far been no cytological analysis of the chromosome mutations induced in somatic cells. By irradiating cells of *D. melanogaster*, in which we knew that somatic pairing was present, we have also wished to extend our previous studies[1], carried out on endoreduplicated Chinese hamster cells, to verify the influence of chromosome pairing on the type and frequency of induced chromosome aberrations.

Third instar larvae of two stocks (Oregon R and *b cn vg bw*) were irradiated with 312.5, 625 and 1,250 R of X rays (180 kV, 6 mA, 3 mm Al and 125 R min^{-1}). At various times after irradiation, samples were prepared by squashing larval ganglia in acetic orcein after fixation for 3 min in a 1 : 1 mixture of methyl alcohol and acetic acid. Before fixation, the ganglia were kept for 2 h in a 0.7% aqueous solution of NaCl containing 10^{-4} M colchicine.

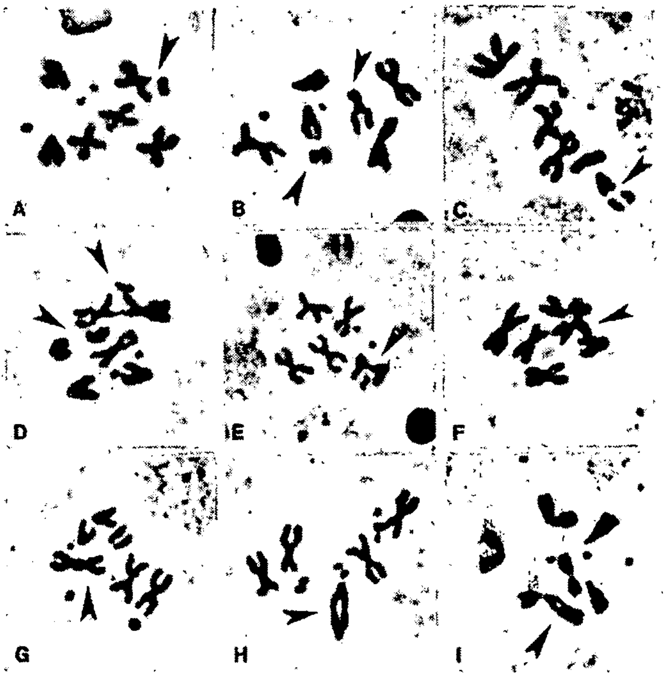

Fig. 1 Induced chromatid and chromosome aberrations in larval ganglion cells of *D. melanogaster*. A, (♀) Terminal deletion of an autosome; B, (♀) isochromatid deletion of an autosome; C, (♂) isochromatid deletion of an X chromosome; D, (♀) asymmetrical exchange between autosomes plus isochromatid deletion of an autosome; E, (♀) asymmetrical exchange between X chromosomes; F, (♀) symmetrical exchange between autosome and X chromosome; G, (♀) dicentric between autosomes with associated fragment; H, (♀) dicentric between X chromosomes with associated fragments; I, (♀) translocation between autosomes.

Figure 1 shows the main types of chromosome and chromatid aberration that we could score in this material. The genome of *D. melanogaster* is suited to this type of analysis, as the

* Significant in χ^2 test with $P < 0.01$.

† An isochromatid deletion can result both from the replication of a chromosome breakage (chromosome deletion) and from an isochromatid breakage. Consequently this type of aberration is present at both early and late fixation times post-irradiation.

1,000 metaphases of at least ten larvae scored for each point.

aberrations are clear and the number of chromosomes per cell is small and two pairs are easily distinguished from the others. In the colchicinised metaphases, the somatic pairing is lost; however, the pairing is clearly present up to late prophase.

Table 1 shows the data obtained in one series of experiments. The experiments were carried out mainly on the Oregon stock and then on the *b cn vg bw* stock for confirmation. The larvae of the Oregon stock irradiated with 1,250 R were killed at various times after irradiation to obtain data on the different stages of the cell cycle: in this way it was possible to study chromatid and chromosome aberrations.

The main result that emerges from the data of Table 1 is that, in the females of both the stocks at all three doses of irradiation, there is a greater frequency of chromosome or chromatid aberrations of every type.

In the present state of our studies it is difficult to determine the cause of this difference: a difference in the efficiency of repair both of premutational damage and of the broken chromosomes might be involved[2,3]. In this respect it is natural to think of the possible presence in the females, as opposed to the males, of the enzymes involved in crossing-over, and of the possibility that, for the formation of a chromosome aberration, some kind of rectification of lesions in DNA is necessary[4,5].

Another fact worth emphasising is the almost total absence in our results of intra-exchanges, either at chromatid or at chromosome level. We maintain that this is one of the effects associated with the chromosome pairing.

Radiochemical Purification of Bacteriophage λ Integrase

BACTERIOPHAGE λ has evolved a highly specific mechanism by which it integrates its DNA into the *E. coli* genome. The product of the lambda gene *int*, which I call integrase, mediates the insertion of the phage DNA at specific attachment sites on both the phage and host genomes[1–3]. A non-enzymatic method by which integrase can be identified in infected cells has been described previously[4,5]. It depends on the observation that in cells which have been heavily irradiated with ultraviolet light before infection with phage λ, synthesis of host proteins and most phage proteins is markedly depressed[6]. Under these conditions a high percentage of labelled amino acids is incorporated into phage-specific proteins including integrase. Using a differential labelling technique, integrase is identified by means of sodium dodecyl sulphate (SDS) gel electrophoresis as the only protein species eliminated by a nonsense (chain-terminating) mutation in the *int* gene.

I describe here the purification of integrase, monitored by electrophoretic assay, to radiochemical homogeneity. In an independent study, Nash[7] has used a similar method to obtain radiochemically pure integrase, which he calls Int protein.

Figure 1*a* illustrates electrophoretic identification of labelled proteins synthesised in a heavily irradiated host by either *int*$^+$ phage or *intam* (*int*29) phage. One major peak at molecular weight 44,000 is synthesised only by the *int*$^+$ phage and is thus concluded to be integrase.

The interpretation that the peak at 44,000 molecular weight is integrase is corroborated by the following experiments. (1) I isolated two additional *int* amber mutants, *int*405 and *int*920, and these mutations also eliminate the peak at molecular weight 44,000. *Int*405 is different from *int*29 and *int*920 since it is suppressed only by $su_{\rm I}^+$ hosts whereas *int*29 and *int*920 are both suppressed by $su_{\rm II}^+$ hosts. (2) The protein peak at molecular weight 44,000 is found if the infection with *intam* phages is carried out in a *su*$^+$ host. (3) The *bio*16-A deletion spans a region of DNA, from the attachment site to within the *int* gene[8], which would code for a polypeptide of molecular weight approximately 22,500 (ref. 9). I have shown that the *bio*16-A deletion eliminates the peak at molecular weight 44,000, thus ruling out the possibility that this peak is coded by a gene adjacent to *int* but is eliminated by *int* amber mutations because of polarity (4) The peak at molecular weight 44,000 is not affected by the non-suppressible mutation *int*6 (ref. 10) or by the temperature-sensitive mutation *int*1 (ref. 11). This experiment indicates that this peak contains the protein defined by the *int* amber mutations rather than a protein under *int* control or a protein controlling integrase production.

We have shown previously that in crude extracts integrase is associated with large, fast-sedimenting particles[5]. Treatment at high ionic strength dissociates integrase from these particles and leaves it in a slower sedimenting form. This observation forms the basis for a purification procedure. Large integrase particles are collected by centrifugation in low salt and then resedimented in 0.66 M KCl. The integrase is then concentrated by ammonium sulphate precipitation and finally fractionated by Sephadex G-100 chromatography. During the purification integrase is monitored solely on the basis of its mobility on SDS gel electrophoresis (see legend to Fig. 1 for details). Gel electrophoresis of radiochemically pure integrase is shown in Fig. 1*b*. The radiochemical purification of integrase represents approximately a 100-fold physical purification. However, the most purified fractions still contain a 100 to 1,000-fold excess of unlabelled proteins.

Depending on its state of purification and on the ionic strength of the buffer, integrase exists in one of three forms, characterised in part by markedly different sedimentation rates. Following sonication, integrase is found in a heterodisperse collection of large (>100S) particles. These particles contain DNA; treatment with pancreatic DNase disperses the large particles into species of 35S or smaller. After purification to homogeneity, all of the integrase sediments in low ionic strength (<0.1 M KCl) as a fairly homogeneous peak at 35S with a broad tail at low molecular weights. It is unlikely that the 35S form is an integrase-DNA complex since treatment of the 35S form with pancreatic DNase has no effect on its sedimentation properties.

Both the large integrase particles found in crude extracts and the 35S aggregate are disrupted by high ionic strength buffers. In 0.66 M KCl, regardless of its stage of purification, integrase sediments as a homogeneous peak at $S_{20,w}$ approximately 4.0. A sedimentation rate of 4S corresponds to a globular protein of molecular weight 60,000. Since the monomer molecular weight of integrase is 44,000 as determined by SDS gel electrophoresis, the 4S form could either be a monomer or a dimer.

Formation of the 35S aggregate is reversible: high salt (0.3 M KCl) disrupts the aggregate, but the aggregate is reformed on return to low ionic strength. This indicates that 35S aggregate formation is an intrinsic property of integrase which has not been lost due to denaturation.

Since integrase catalyses a site-specific recombination event *in vivo*, radiochemically purified integrase might inter-

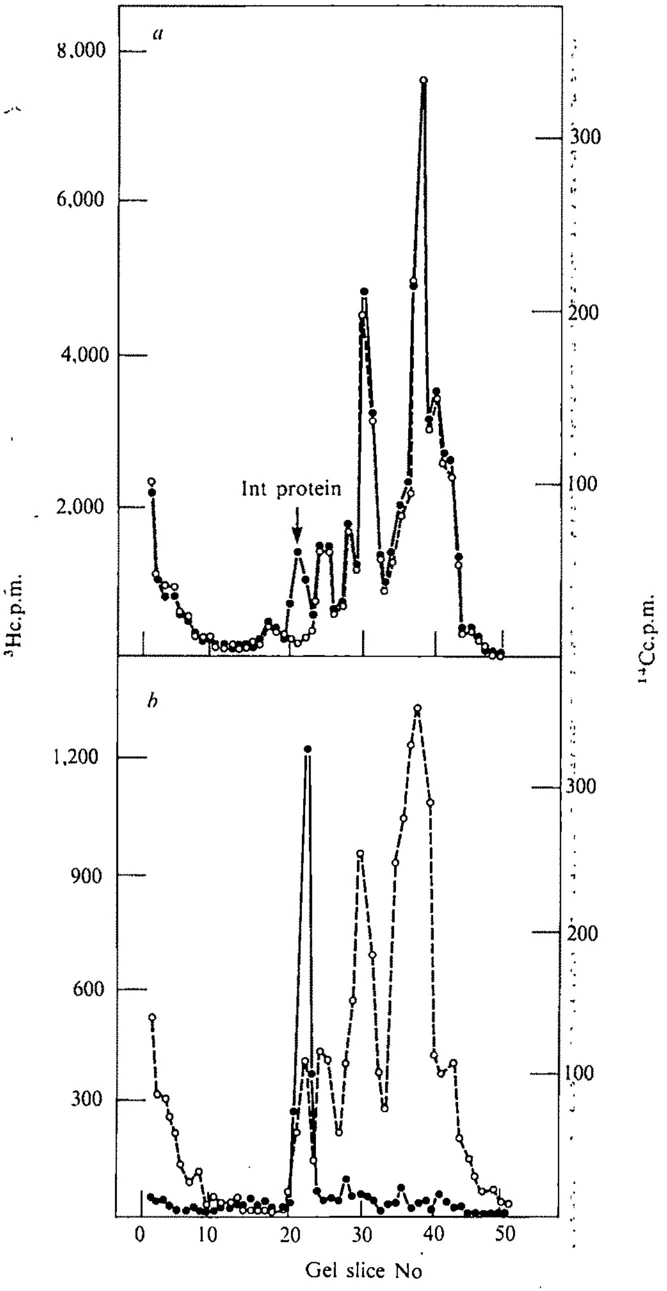

Fig. 1 Electrophoretic identification and radiochemical purification of integrase. *Escherichia coli* strain 159 (*su$^-$gal$^-$str-r uvr$^-$*) was grown at 37° C to a density of 3×10^8 ml^{-1} in I medium (0.37% Na$_2$HPO$_4$, 0.3% KH$_2$PO$_4$, 0.25% NaCl, 0.00075% FeCl$_3$, 0.4% maltose, 0.001 M MgSO$_4$). The culture was chilled and then irradiated in 120 ml aliquots in an 18 × 8 inch dish with two 15 watt GE germicidal bulbs at a dose of 8,400 ergs mm^{-2}. Ten 100 ml aliquots of the irradiated culture were added to ten prewarmed flasks containing 1 mCi ^{3}H-leucine (50 Ci mmol^{-1}) and 2 ml 1.0 M MgSO$_4$, and infected with λ*Eam4b2red*β*am270cI857Sam7* at a multiplicity of five particles per cell. Two further 100 ml aliquots of irradiated cells were treated in the same way, except that one was labelled with 25 μCi ^{14}C-leucine (250 mCi mmol^{-1}) instead of ^{3}H-leucine and the other was infected with λ*Eam4b2intam29red*β*am270cI857Sam7* and labelled with 25 μCi ^{14}C-leucine (250 mCi mmol^{-1}). After incubation for 1 h at 37° C, the combined ^{3}H-labelled cultures and the two ^{14}C-labelled cultures were washed repeatedly with cold I medium and each resuspended in 5 ml TMES buffer (0.01 M Tris, *p*H 7.5, 0.001 M MgCl$_2$, 0.0002 M EDTA, 0.1 mg ml^{-1} dithiothreitol). Each culture was sonicated with cooling for 1.5 min at 60 W and then centrifuged at 10,000 r.p.m. for 10 min to remove debris. The ^{3}H-labelled lysate was further purified by sedimentation into a 2 ml 50% glycerol cushion in TMES buffer at 4° C for 3 h at 40,000 r.p.m. in an IEC SB283 rotor. The glycerol cushion was brought to 0.67 M KCl and 10% glycerol and then spun at 4° C for 12 h at 25,000 r.p.m. in an IEC SB110 rotor onto a 23 ml 40% glycerol cushion containing 0.67 M KCl and TMES buffer. The supernatant fluid above the cushion was collected and brought to 75% saturation with cold, neutralised, saturated ammonium sulphate. After incubation overnight at 4° C, the precipitate was collected by centrifugation at 4° C for 30 min at 18,000 r.p.m., resuspended in 2 ml TMES buffer supplemented with 50 μg ml^{-1} bovine serum albumen (BSA) and 10% ethylene glycol, applied to a 1.5 × 30 cm Sephadex G-100 column equilibrated with the resuspension buffer, and then washed through with the same buffer at 4° C at a flow rate of 10 ml h^{-1}. The fractions containing material excluded from the column were pooled and found to contain 60–80% of the integrase applied to the column. The yield from crude extract was 35%. Integrase was monitored during purification solely on the basis of its mobility on sodium dodecyl sulphate (SDS) gel electrophoresis. This was made possible by the construction of special phages containing a combination of amber mutations (*Eam4* and *red*β*am270*) and a deletion (*b2*) such that they synthesised no other proteins with an electrophoretic mobility near that of integrase. To ensure the correct identification of integrase during the purification, each SDS gel of a ^{3}H-labelled fraction was internally calibrated with unfractionated ^{14}C-labelled *int*$^+$ or *intam* lysate. In preparation for gel electrophoresis equal aliquots of ^{3}H-labelled fractions and unfractionated ^{14}C-labelled lysate were combined and incubated at 90° C for 5 min with 0.2% SDS and 0.1% dithiothreitol. A 0.05 ml sample of this mixture was subjected to electrophoresis on a 5 × 0.6 cm 10% acrylamide gel. *a*, Unfractionated ^{3}H-labelled *int*$^+$ lysate (●) plus unfractionated ^{14}C-labelled *int* amber lysate (○); *b*, purified ^{3}H-labelled integrase (pooled G-100 fraction) (●) plus unfractionated ^{14}C-labelled *int*$^+$ lysate (○). Electrophoresis is from left to right.

act specifically with DNA which contains the phage attachment site. To test the possibility of specific *in vitro* binding, radiochemically pure integrase was cosedimented with DNA in glycerol gradients or incubated with DNA and then filtered through nitrocellulose filters.

Integrase in the 4S form does not bind to DNA either specifically or non-specifically, probably due to the relatively high salt concentration (>0.3 M KCl) necessary to maintain the 4S state. On the other hand, when 35S integrase aggregates are mixed with a large molar excess (500–2,500-fold) of 32S λ DNA, the integrase sediments with the DNA at approximately 32S. The same result is obtained with both wild type DNA and with DNA which has the attachment site deleted (*att*∇). These results suggest that 35S integrase binds non-specifically to λ DNA, and further, that this binding disrupts the 35S aggregate. This interpretation was tested by the following experiment. Integrase aggregates (35S) were cosedimented with a mixture of whole *att*$^+$ DNA and sonicated *att*∇ DNA (and *vice versa*). If the 35S aggregates disperse when binding non-specifically to DNA, then a significant amount of integrase should sediment with the sonicated *att*∇ (or sonicated *att*$^+$ DNA) at 5S. The result of this experiment is shown in Fig. 2: after sedimentation, the integrase partitioned almost equally between the *att*$^+$ and *att*∇ DNAs. As above these results give no indication of specific binding and, in addition, make it seem unlikely that a relatively weak non-specific binding is obscuring a much stronger specific binding to the attachment region. There was no increase in binding specificity over a wide range of salt concentrations and in various buffer systems containing different cations.

In addition to binding to λ DNA in glycerol sedimentation gradients, radiochemically pure 35S integrase aggregates bind λ DNA to nitrocellulose filters. The filter-binding activity in the preparations was shown to be due specifically to integrase since material from an *int* amber infection, carried through the same stages of purification as the *int*$^+$ lysate, did not display any filter-binding activity. Integrase displayed the same amount of filter-binding activity with both *att*$^+$ and *att*∇ DNA.

The experiments described here demonstrate that partially purified integrase binds non-specifically to λ DNA and

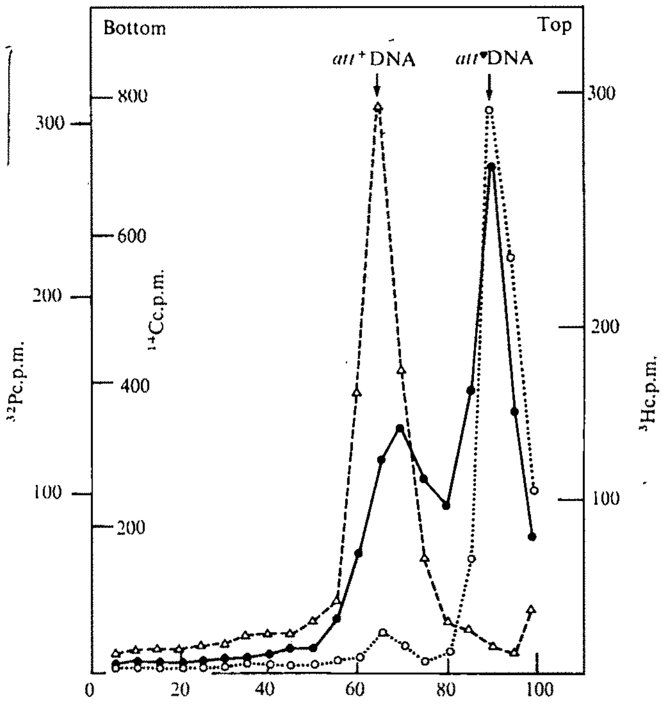

Fig. 2 Cosedimentation of 35S integrase with whole *att*$^+$ and sonicated *att*▽ λ DNA. A 50 μg ml^{-1} solution of ^{14}C-labelled λ*b104cI857Sam7* DNA (*att*▽) was sonicated with cooling for 2 min at 60 W in 0.01 M Tris, *p*H 7.5, and 0.001 M EDTA. A 25 μl aliquot of radiochemically purified integrase in the 35S form (pooled G-100 fractions from Fig. 1) was incubated at 4° C for 1 h with a mixture of 5 μg whole ^{32}P-labelled λ*cI857Sam7* DNA and 5 μg sonicated ^{14}C-labelled λ*b104cI857-Sam7* DNA. The incubation mixture contained 0.01 M Tris, 0.001 M MgCl$_2$, 50 μg ml^{-1} BSA, and 10% ethylene glycol. The DNA-integrase mixture was layered on 3.6 ml 10–30% linear glycerol gradient containing the same ingredients as the incubation buffer, and then spun at 4° C for 2 h at 60,000 r.p.m. in an IEC SB405 rotor. The gradient was dripped directly into scintillation vials and counted. When the experiment was repeated with sonicated *att*$^+$ DNA and whole *att*▽ DNA, essentially the same result was obtained, that is, integrase counts partitioned approximately equally between the whole and sonicated DNAs. When integrase was cosedimented only with sonicated *att*$^+$ or *att*▽ DNA all of the integrase sedimented with the sonicated DNAs. ^{3}H-labelled integrase (●); ^{32}P-labelled λ*cI857Sam7*(*att*$^+$) DNA (△); ^{14}C-labelled sonicated λ*b104cI-857Sam7* (*att*▽) DNA (○).

reversibly forms a fairly homogeneous aggregate which sediments at approximately 35S. With further purification of integrase it may be possible to demonstrate the existence of an integrase-mediated reaction specific for attachment region DNA and to elucidate the role of the 35S aggregate in this process. One can speculate, for example, that the 35S aggregate functions as a structural cage to hold pairs of attachment sites together.

I thank Ethan Signer for many helpful discussions and for constant support, Howard Nash for useful exchanges of unpublished data, Paul Voynow for help with the filter binding assays, and Bodil Madsen for technical assistance. This work was conducted under the tenure of a US National Science Foundation graduate fellowship and was supported by grants from the National Institutes of Health and the American Cancer Society to Dr Ethan Signer.

Changes in Rates of Increase in Size and of Exoskeletal Production during Old Age in the Isopod *Ligia oceanica* (L.)

THE male isopod *Ligia oceanica* (L.) goes on moulting and growing even when its spermatogenesis has come to an end[1–4]. The coexistence of growth and senescence seems to me an unexpected finding in a higher metazoon. It is possible to split up the postpuberal growth period of *Ligia* into the sexually mature stage and the senescent stage, both of which are states of morpho-physiological equilibrium, and an intermediate transitional phase. The term 'stage' is here used as equivalent to the French term *étape* and is composed of several 'stadia' separated by a moult. In the sexually mature stage the gonads are fully developed, in the senescent stage they are degenerated. The transitional phase is characterised by various degrees of testicular degeneration.

Sexual deterioration is not, of course, the only criterion of senescence, and I have shown[5] that the respiratory rate falls off strongly during the senescent stage. In another study[6], weight and calcium content of the exuvium were found to vary more during the senescent stage than during the sexually mature stage. I thought that loss of vitality would thus lead to greater metabolic irregularity of exoskeletal formation and of exuviation and calcification, and wondered whether the senescent animal is different from the younger adult in other quantitative exoskeletal characters than merely greater exuvial variation. I have therefore undertaken a comparative study on the growth rate during the two stages and the transitional phase.

Isopods were collected during the spring tides on the coast of Normandy (Luc-sur-Mer, Calvados, France, in May 1966 and July 1967). Some 200 premoulting adult males of various sizes were then reared in the laboratory at a temperature of 17° C, for two successive moults. Most survived

Table 1 Rate of Increase of Head Breadth

Stage or phase	Number of individuals	$\bar{R}$	σ
Sexually mature	27	1.0702	0.00652
Transitional	30	1.0471	0.00691
Senescent	27	1.0155	0.00449

The rate R is defined by $R = H_1^{-1}H_2$, where H_1 and H_2 are the head breadth at two consecutive stadia. $\bar{R}$, geometrical mean of R; σ, standard deviation of log R.

a first moult but only eighty-four survived the second. The head breadth and the dry weight of the exuvium of each individual were measured.

The growth rate from one stadium to the next generally varies with the environment, and in crustacea seems to be lower in the laboratory than in the wild. In the premoult state where the animals were caught, the conditions that determine the characteristics of the moult were, however, already laid down. A comparison of the exuviae of first and second moult, which show sizes of animals at the two successive stadia before and after capture, may therefore give a fair picture of growth rate in the wild.

The treated animals were divided into three groups corresponding to the two stages and the transitional phase. The geometrical mean of the growth rate was calculated for each group (Table 1). The growth rate was markedly lower in the senescent stage than in the sexually mature stage; the difference (reckoned by a t-test carried out on the logarithm of the growth state) is highly significant ($P<0.001$).

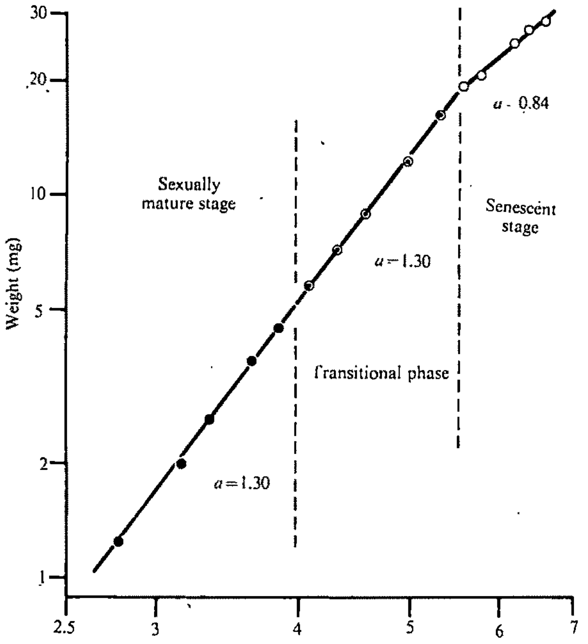

Fig. 1 Relative increase of weight (W) to head breadth (H) of the exuvium. Each point stands for the geometrical mean of ten individuals. a, Regression coefficient of log W on 3 log H.

I then studied the relation of weight (W) to head breadth (H) of the exuvium in 150 individuals, to estimate the rate of exoskeletal production at each stadium. This should give an indication of anabolic intensity and thus of growth capacity in mass. The individuals belonging to each stage or phase were grouped by tens according to their H value. The geometrical means of H and W for each such class were plotted on a double logarithmic grid (Fig. 1). The figure displays a similar growth curve for the sexually mature stage and for the transitional phase, but the curve for the senescent stage is different, with a lower regression coefficient a of log W on 3 log H. Reeve's stochastic test[7] shows this difference of a to be highly significant ($P<0.001$). The growth rate in mass may be deduced, from this lower value of a, to fall off with old age. Thus, although an aged isopod can moult and grow, notwithstanding testicular degeneration, its senescence is fairly marked by a fall in the rates of increase of size and mass.

Lantern Fish compare Downwelling Light and Bioluminescence

THE biological utility of the light organs of oceanic fishes has been the subject of much speculation[1,2]. According to one hypothesis the ventral photophores of some mesopelagic fishes in the upper regions of the sea may produce bioluminescence that matches the colour and intensity of environmental light passing downwards on either side of the fish. Such a system of camouflage could obscure the ventral outline of the fish when viewed from below[3,4].

This hypothesis is supported by several lines of evidence. First, light in the sea is highly directional, the ratio of upward to downward directed light being small (1:200 to 1:100) in clear oceanic waters. Consequently, the reflecting dorsal and lateral surfaces of a fish enable it to match the background when viewed from above and from the side, but the ventral silhouette seen from below would appear dark against the brighter background[5]. Second, the blue wavelengths of the spectrum penetrate most deeply into the ocean, and therefore daytime illumination at depths of 500 to 1,000 m is blue and dim. Bioluminescence of some midwater fishes is blue and falls within the range of intensities measured during the day at these depths and has a very similar angular distribution[6–9].

One species of midwater fish has proved invaluable in the study of this hypothesis and its implications. *Tarletonbeania crenularis* is a common lantern fish (Myctophidae, Iniomi) living in the North Pacific Ocean in deep water beyond the continental shelf. Unlike many other mesopelagic fish, this species migrates to the surface at night from daytime depths of 500 to 1,000 m and is often associated with sonic scattering layers[10–12]. Lantern fishes are bioluminescent. Light organs or photophores occur in rows along the ventral surface of the head and body and groups of isolated organs may be found around the eyes. Each dermal photophore consists of a mass of innervated photogenic tissue backed by a pigmented mantle and reflector. Some light organs are covered by a superficial lens, scale and reflector system which concentrates and collimates the light from the photogenic tissue and modifies the colour and intensity of the emitted light[13–15].

If the ventral surface of a lantern fish is to remain invisible in the face of changing intensities of incident light, the fish should be able to monitor both the environmental illumination and the activity of its photophores. *Tarletonbeania crenularis* may see downwelling light and bioluminescence from a supraorbital photophore, and adjust the output of its ventral photophores to match environmental illumination.

Lantern fishes swimming near the surface on calm, dark nights are attracted to an underwater light and can be collected with dipnets and maintained in fairly good condition in darkened aerated aquaria for several hours. Fishes kept in total darkness rarely luminesced, but when they were illuminated from above with blue light the ventral photophores of some specimens emitted a bluish light lasting for about 15 min which approximated the colour and intensity of the incident illumination and which was extinguished when the incident illumination was turned off. The bioluminescence was only visible after about 30 min of dark adaptation on the part of the observer when the intensity of the incident light was very dim. It was not possible to determine whether the supraorbital photophore was luminescing simultaneously with the ventral photophores as the bioluminescence very closely resembled the colour and intensity of the incident light, and the relationships of the orbital photophores to the eyes of *Tarletonbeania* were studied for evidence of a feedback loop between the bioluminescent and visual systems.

The eyes of lantern fishes are large and well adapted for vision in dim light. The nearly spherical lenses of a 41 mm ♀ *Tarletonbeania* were 1.3 mm in diameter and protruded well through the pupils; the centres of the lenses were nearly in line with the iridial margins and coincident with the centres of the pupils (Fig. 1). The protruding lenses of fishes (refractive index 1.67) compensate for the absence of corneal refraction, since corneal tissues have the same refractive index (1.33) as water[14].

The eye of *Tarletonbeania* is particularly distinguished by the presence of a crescent shaped gap or aphakic aperture between the central margin of the iris and the ventral border of the lens. This aperture has not been described in lantern fishes before but is found in other bathypelagic species[15]. The aphakic aperture of *Tarletonbeania crenularis* is so placed that light rays from the supraorbital photophores and from the dorsal visual fields can reach the retina (Fig. 2).

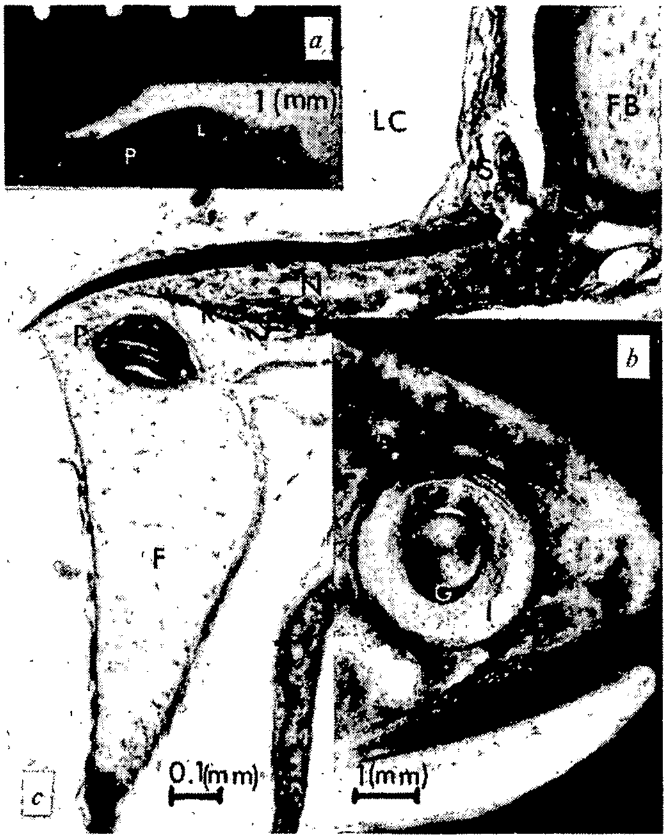

Fig. 1 Structure of the eye and supraorbital photophore of the lantern fish, *Tarletonbeania crenularis*. *a*, Dorsal view of the left eye of a 41 mm ♀ specimen, showing the protruding lens, L, subjacent to the cornea, and P, the position of the supraorbital photophore. *b*, 10 μm paraffin section stained with Mallory triple connective tissue stain; F, transparent fold of tissue in which photophore, P, is located; R, reflector; N, branch of supraorbital nerve; SN, innervating the photophore; FB, frontal bone; LC, supraorbital lateral line canal; C, cornea. *c*, A lateral view of eye of *Tarletonbeania* showing the supraorbital photophore; P, (the fold of tissue over photophore has been removed); L, lens; G, aphakic aperture between lens and the iridial margin; I, iris.

The supraorbital light organ (depicted in figures of Bolin[18], but not described) is situated in a flap of tissue at the posterodorsal margin of the orbit. This organ is innervated by a branch of the supraorbital nerve and is enveloped posteriorly and medially by a reflector and pigmented epithelium (Fig. 1*b*)[16].

Light from the supraorbital photophore falls on the posterior-superior surface of the lens and the anterior-inferior quadrant of the retina. The approximate paths of light rays from the supraorbital photophore and from the dorsal visual fields through the lens and onto the retina were constructed ignoring corneal refraction. The distances from the supraorbital photophore to the surface of lens, the diameter of the lens, and the size of the aphakic aperture were measured from photographs of dissected preparations and histological sections. An almost constant feature of fish eyes is the ratio of the distance from the centre of the lens to the retina divided by the radius of the lens. This ratio (Matthiessen's ratio) is about 2.55 and it was used to obtain the distance from the centre of the lens to the retina to compensate for errors in measured distances created by artefacts of fixation. Snell's law and a value of 1.67 for the refractive index of the lens were used to determine the angles of refraction at the surfaces of the lens[17-19]. The constructed path of light rays from the supraorbital photophore was confirmed by splitting the head of a fresh fish, dissecting the orbit away from the back of the retina, and directing a beam of light from a fibre optic system from the anterior retinal quadrant backwards through the aphakic aperture and lens and onto the supraorbital photophore.

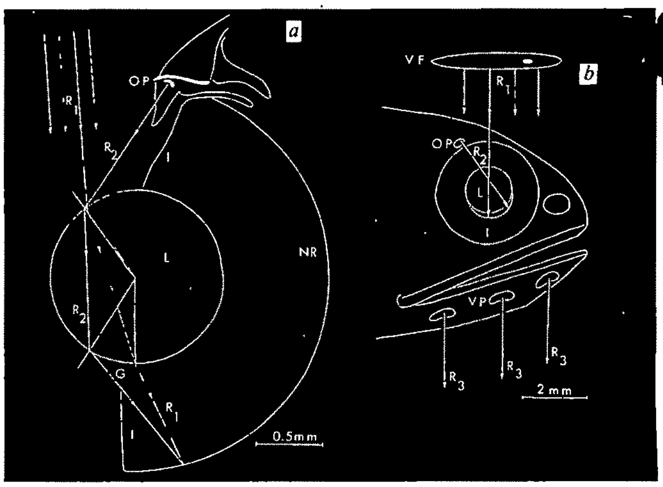

Fig. 2 Optical paths taken by light from the dorsal visual field and from the supraorbital photophore of *Tarletonbeania crenularis* through the dioptric media of the eye. *a*, Diffuse downwelling light from the dorsal visual field, R_1, and a ray of light, R_2, from the supraorbital photophore, are bent by the lens, L, and fall on the neural retina, NR. Some light passes through an aphakic aperture, G, between the iris, I, and the lens. *b*, A lateral view of light rays R_1 from the dorsal visual field, VF, and R_2 from the supraorbital photophore, entering the eye through the aperture between the lens, L, and the iris, I. The fish may see a spot in the visual field cast by light from the supraorbital photophore, if the intensities of R_1 and R_2 are unequal. If the fish adjusts the intensity of R_2 to equal R_1 and controls the output, R_3, of the ventral photophores, VP, accordingly, then the ventral body outline will be camouflaged maximally.

These findings suggest that *Tarletonbeania crenularis* can see a diffuse spot of light cast by the supraorbital photophores in the dorsal visual fields whenever the intensity of the light from the photophore is greater than that of the dorsal visual field. It might be supposed that the fish can perform an incremental threshold discrimination of intensity and adjust the output of the supraorbital photophore until the spot is obliterated. If the fish controls the intensity of light from the ventral photophores accordingly it will not be visible from below against changes in downwelling illumination.

For the photophore system to be maximally effective in camouflaging the ventral body silhouette, a luminescing fish should be horizontally orientated. Observations from bathyscaphes[20,21] show that some non-luminescing mytophids were orientated in positions other than the horizontal.

Rate of Uptake of DDT from Soil by Earthworms

SINCE 1958, when the occurrence of DDT and its metabolites in the tissues of earthworms was first reported, there have been more than twenty other reports of DDT residues being found in these animals[1,2]. The amounts found have differed greatly, ranging from minute traces to concentrations of nearly 700 p.p.m., although concentrations of the order of 1 to 10 p.p.m. have been more commonly reported. Sometimes the concentrations of DDT residues found in the earthworms have been less than in the soil where they live, although the tissues of the worms have usually contained greater concentrations than the surrounding soil. When all the published data were considered, it was seen that there is a linear correlation between the concentration of DDT (and other organochlorine insecticides) in earthworms and that in the corresponding soil[1]. Not all species concentrate insecticides in the same way or to the same degree[3]; *Lumbricus terrestris* and other species with permanent burrows take up DDT from the soil surface more readily than from residues that have been thoroughly mixed into the upper strata of soil. Conversely, some of the species without permanent burrows, that tunnel haphazardly through the upper 150 mm of soil, take up more residues from insecticides evenly distributed through the upper soil layers to plough depth.

One limitation of the published data is that, in most investigations, residues in samples of soil and earthworms were taken at some arbitrary point in time, without defining the period during which the worms were exposed to soil insecticide residues; so such random samples may represent any stage in what is possibly a long process of absorption and concentration. The rate of uptake or excretion of DDT by earthworms has not been studied.

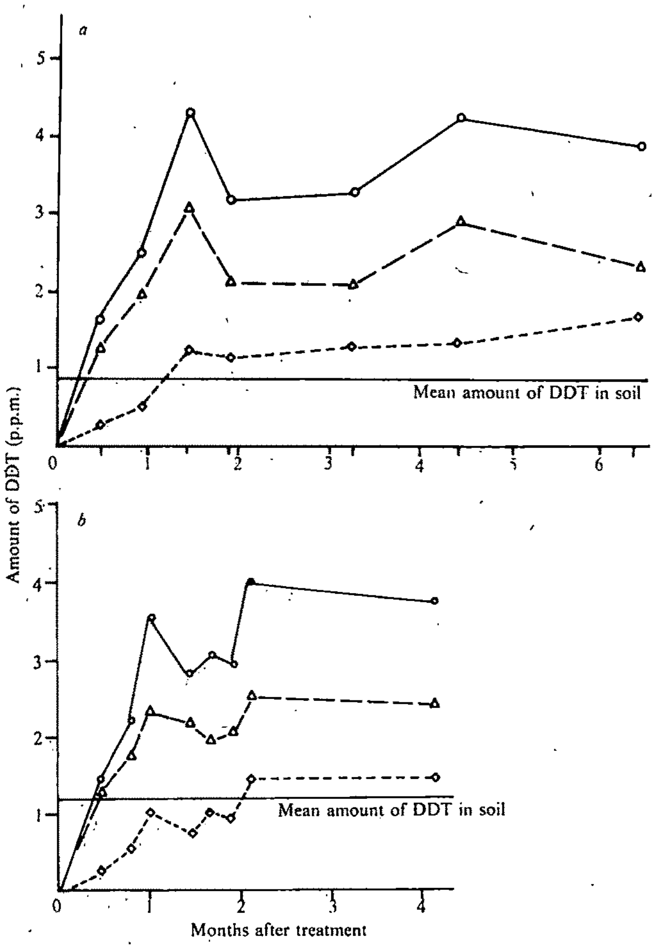

Fig. 1 Results of two series of uptake experiments. ○, DDT and DDE; △, DDT; ◇, DDE.

We therefore investigated the process in a series of laboratory experiments. Uptake of DDT into earthworms was followed in twelve culture boxes (450 mm high × 180 mm wide × 90 mm deep) with wooden sides and perspex backs and fronts that could be easily removed, containing DDT-treated soil. Each box contained ten healthy *Lumbricus terrestris*. This soil, which was free from insecticides before treatment, was passed through a 6 mm aperture sieve to remove stones and debris and was then spread out on a large plastic sheet, sprayed with DDT through an atomiser and thoroughly mixed before being placed in the culture boxes. The dose of DDT was calculated to give approximately 1 p.p.m. ($\mu g\ g^{-1}$) in the soil. Four worms were taken from culture and put separately into Petri dishes containing moist filter paper for 24 h, to allow their gut contents to be voided, then stored at 15° C for several days before being analysed for residues. Small soil samples were taken from each box at the same time, and bulked before extracting the DDT residues.

The excretion of DDT from worms that had lived in soil containing DDT for their entire life cycle was studied by taking sixty such worms from contaminated soil in the field and placing them in culture boxes containing uncontaminated soil. At intervals, batches of four worms were taken at random from the boxes and residues analysed in the same way as in the uptake experiments.

Residues were extracted by grinding frozen worms with four times their weight of anhydrous sodium sulphate, and tumbling for 2 h with a mixture of 100 ml of acetone and 100 ml hexane in polythene-capped jars. The extracts were left to stand until the sediment settled, filtered through a Gooch funnel, transferred to a separating funnel and shaken with 100 ml 2% sodium sulphate solution. The aqueous phase, which settled at the bottom of the funnel, was run off and the remaining hexane/acetone extract stored at 0° C with a little anhydrous sodium sulphate until analysed by gas-liquid chromatography (GLC).

The soil from which the earthworms were taken was analysed for DDT by grinding 50 g of the soil, taken in many small subsamples from the four boxes, with 50 g sodium sulphate, and tumbling in an acetone/hexane mixture for 4 h. The subsequent procedure was the same for the worm extracts.

Small aliquots of the soil or worm extracts were concentrated in a Kuderna-Danish evaporator, and passed through a column of Celite impregnated with a sulphuric acid-oleum mixture to remove most of the interfering substances, but not DDT or DDE which is the principal degradation product. The amounts of DDT and DDE in the final extract were determined by GLC using a stainless steel column (1 m long, 3 mm diameter) packed with 5% SE30 on Chromosorb W and operated at 185° C. An electron-capture detector was used with nitrogen as a carrier gas.

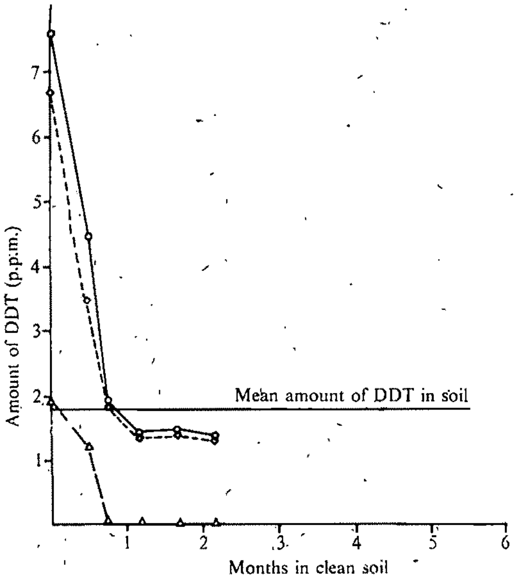

Fig. 2 Results of the excretion experiment. Symbols as in Fig. 1.

The results of the uptake experiments are summarised in Fig. 1*a* and *b* and those of the excretion experiment in Fig. 2. Because the earthworms were progressively removed for analysis or died, it was impossible to continue the experiments for more than 6 months. This period was, however, sufficient to show that worms accumulated the maximum amount of DDT residues from soil after about 1 month; thereafter, although there were small fluctuations, the amounts did not change greatly. There seemed to be three phases—an initial fairly rapid uptake followed by some loss, then a further uptake before equilibrium was reached. Similar double maxima have been reported for the uptake of DDT by other animals such as snails[4] and aquatic organisms[5]. The explanation has generally been that the initial rapid uptake is due to ingestion, whereas the slower phase represents redistribution or residues within the organism, but this needs confirmation. There was evidence that in the box experiment conversion of DDT to DDE within the worms continued and this was confirmed with worms taken from the field; in the latter there was much more DDE than DDT. Moreover, worms placed in untreated soil excreted DDT rapidly, but some of the DDE persisted in their tissues for several months. Some workers have reported larger amounts of DDT than DDE in worms[3,6–8], but others found either the reverse[9] or that there could sometimes be more DDE and sometimes less[10].

There seems little doubt from our experiments that DDE persists longer in worm tissues than DDT. The presence of DDE in worms indicates that they contribute significantly to the initial degradation of DDT, because the amount of DDT converted to DDE in soil is small, possibly only of the order of 10% over several months or even years. During the period of our experiments there was virtually no conversion of DDT to DDE in soil (only traces of DDE being found in the extracts), whereas nearly half the DDT taken up by worms was converted to DDE in 4 to 6 months; and in worms that had been exposed to DDT for a long time, nearly all the residues were DDE.

Effects of Interrupted Light on Plant Disease

Results of experiments with scab disease on MM109 apple rootstock shoots showed a marked lack of reproducibility, even when done in a glasshouse with some control of light and humidity as well as temperature (the mean visible light intensity was controlled to 1,300±200 cal per cm^2 per month[1], ambient temperatures to 20±2° C during the day and 15±2° C at night with corresponding relative humidities of 70%±5% minimum and 90%±5% maximum). The disease system seemed to be very susceptible to residual fluctuations in the environment. Although this situation could be partly attributed to mechanical failures, examination of results and sunlight radiation records collected over a period of years indicated that erratic and short reductions in sunlight intensity, due to small cumulus clouds passing during the end of the first week after infection, could account for a considerable part of the irregularity. This study, though stimulated by previous observations on apple scab disease, was done with *Venturia inaequalis* and *Podosphaera leucotricha* on MM109 apple rootstock shoots, and strawberry latent ring-spot virus on cucumber plants, in order to investigate the influence of interrupted light on plant disease generally.

Groups of inoculated plants were separated by opaque partitions under a timber-framed hood covered with black polythene to exclude approximately 90% of the daylight, and were illuminated by wide spectrum Kolorarc lamps (Phillips Ltd). Plants received continuous unmodulated light during the day, or were shaded at intervals for 2-min periods by the passage of automatically controlled reciprocating metal shutters, which excluded approximately 90% of the incident light when closed. All plants had at least 12 h of uninterrupted light on the day prior to inoculation. The cucumber plants were subjected to a 16 h day, and when shaded received two, four, or six periods per h every day for 7 d after inoculation because of the rapid onset of the virus disease (see Fig. 1).

Before inoculation of the apple rootstock shoots, the first fully unrolled and partially expanded leaf below each shoot tip was labelled on the petiole and designated Lo, the two leaves above being +1 and +2 and the two below −1 and −2. After inoculation with either *V. inaequalis* or *P. leucotricha*, the following light treatments were applied during 12 h days: (a) unmodulated light for the first 6 d; (b) unmodulated light for the first 4 d followed by 2-min shaded periods twice per h during the fifth and sixth days; (c) as (b) but with four 2-min shaded periods per h; (d) as (b) but with six 2-min shaded periods per h. The plants were subjected to normal glasshouse conditions for the rest of the test period. For both the diseases the numbers of lesions appearing on the five recorded leaves of each shoot ere counted during the tenth to the twenty-first days after fection. Light intensities were adjusted in all experiments compensate for the effects of the shaded periods. Leaf temperature changes in these conditions were comparable with those occurring in naturally modulated sunlight. The mean visible light received by plants while being treated was 30 ± 5 cal per cm^2 per day.

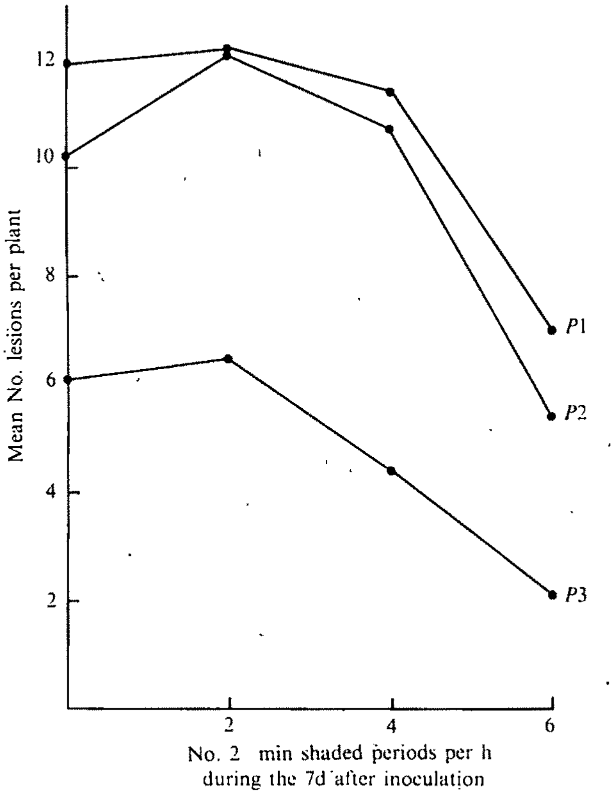

Fig. 1 Inhibition of strawberry latent ringspot virus disease on cucumber plants by the application of six 2-min shaded periods per hour. (Experiment repeated three times for which P_1, P_2 and P_3 are <0.001, respectively.) Cucumber seedlings (cultivar, Ohio), potted singly into 3-inch plastic pots, were inoculated on the cotyledons 7 d after sowing. A strain of strawberry latent ringspot virus (X/XX/XS/SS/Ne Nepo virus group), isolated from blackberry, was maintained in cucumber source plants. Young leaves from plants with symptoms were collected 40 d after inoculation and ground with a pestle and mortar (1 g leaf to 5 ml of 0.03 M phosphate buffer, *p*H 8). The inoculum was rubbed on to cotyledon leaves using the forefinger, plants being taken singly from the different treatment groups in turn, between 1000 h and noon. The cucumber leaves were then washed with distilled water and placed immediately under their respective treatments. Seven days after inoculation a count was made of the number of chlorotic primary lesions, which were best seen by transmitted light. There was no diminution of disease under unmodulated light when the total light received was reduced by the same amount either by day length or light intensity. These effects were readily reproduced.

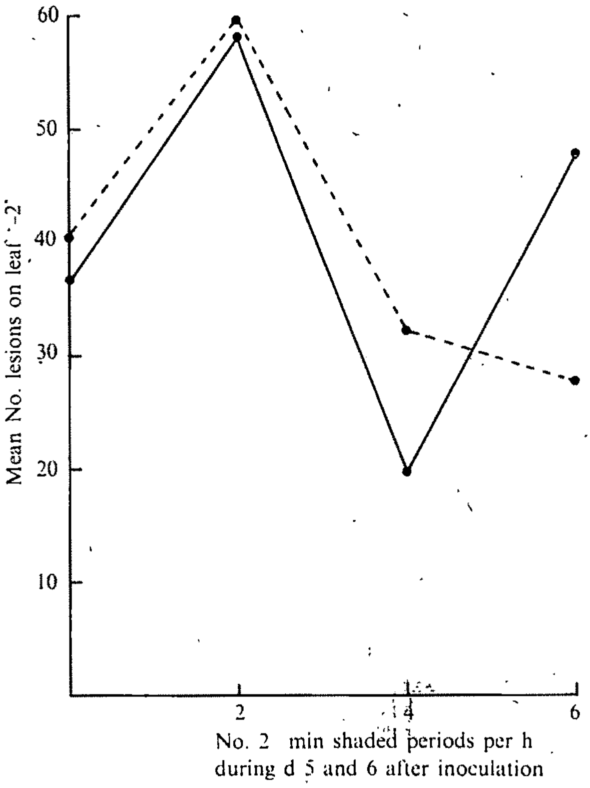

Fig. 2 Effects of interrupted light on the incidence of mildew on apple leaves approaching maturity at the time of infection. ●—●, Control; ● - - - ●, kinetin. Plants were placed in an inoculation tower for mildew infection[2] 24 h before inoculation and removed 18 h afterwards. Inoculum was obtained from four to six heavily infected apple rootstock shoots, to give well-spaced lesions[2]. Kinetin solution (60 mg l^{-1}) was applied to each shoot as a spray at the rate of 3 ml per ten plants, 2 and 3 d after inoculation. The disease was greatest when the shaded periods were applied twice per hour, and least when applied four times per hour ($P<0.001$). Intermediate effects occurred on plants receiving continuous light or six shaded periods per hour during the day. This result was reproducible on either primary or secondary shoots. Kinetin altered the response of the disease to the effects of six shaded periods per hour ($P<0.05$).

The effects of light interruptions on disease reported here, we think for the first time, were impressive yet quite different on each of the systems tested. Experiments with the two obligate parasites gave results which were readily reproducible, in contrast to those given by *Venturia inaequalis.* This facultative parasite, although very susceptible to the way in which light is received, seems to be influenced by other environmental factors which make reproducibility difficult to achieve. The effects of temperature during infection, and of preinoculation conditioning of the plants, are under investigation. The scab and mildew experiments showed the effects of light interruptions to be most marked on leaves approaching maturity at the time of inoculation, though they were visible on all the recorded leaves.

Previous work showed that kinetin can alter both the amount and vertical distribution of the scab disease on the apple shoot, strongly suggesting that the disease is affected by the hormone system of the host[4,5]. The effect of kinetin on apple plants with mildew, when subjected to six light interruptions per hour during the fifth and sixth days after infection, supports the previous suggestion and also indicates that the response to interrupted light is hormone-dependent.

Many plant diseases respond to changes in photoperiod, which in the long term will alter the amounts of available photosynthate. Thus the application of long dark periods both before and after infection affected the growth of bacterial leaf blight on bean, cucumber, cotton and soybean[6].

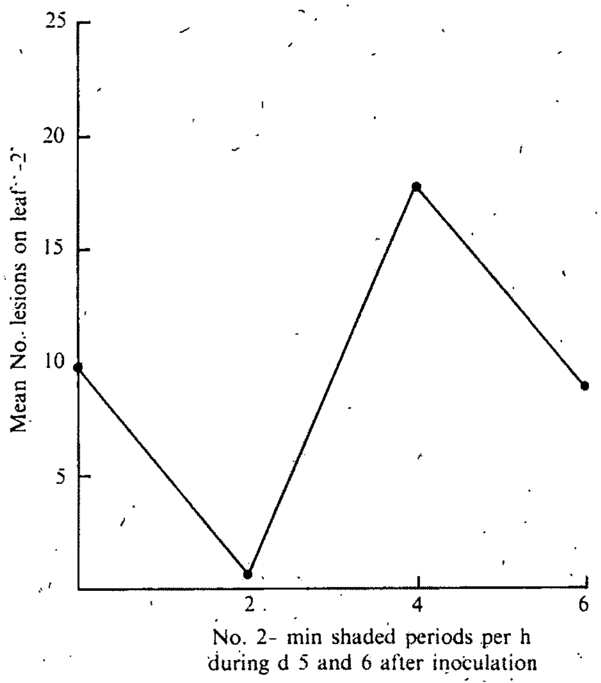

Fig. 3 Effects of interrupted light on the incidence of scab on apple leaves approaching maturity at the time of infection. Cultures of *Venturia inaequalis* (Clone E1)[3] grown on filter paper cylinders standing in 10% (w/v) malt extract solution were used as the source of inoculum in the apple scab experiments. Each shoot was individually sprayed, using compressed air, at the rate of 3 ml per ten plants, the inoculum density being approximately 50,000 conidia per ml[4]. The most striking effects occurred after the application of two, or four, 2 min-shaded periods per hour ($P < 0.001$). Seventy-five per cent of the leaves were apparently immune after receiving two shaded periods per hour and the maximum number of lesions seen on a leaf after treatment was five. By contrast, shading applied four times per hour resulted in only 25% of the leaves showing no disease and a maximum of forty-seven lesions on a leaf.

Young leaf disks inoculated with tobacco mosaic virus produced more virus under the influence of increased light whereas older disks did not respond[7]. The development of *Verticillium* wilt in sunflower was reduced by shortening the day length, but was restored to normal when the light deficit was eliminated by a period of illumination applied during the night[8]. Light also affects the hormone system of plants as indicated by the control of apical dominance in *Phaseolus vulgaris*[9] and by flower initiation in several plant species when light is applied as an intermittent supplement[10]. Since in our experiments the total amounts of light received by the plants were approximately equalised between treatments, thereby reducing variation in amounts of photosynthate, the results indicate that the disease responses to 2-min shaded periods were a function of the hormone systems.

We conclude that the reproducibility of quantitative experiments with many plant diseases will depend upon controlled modulation of incident light, in addition to the accepted standards of light intensity, temperature and humidity. Controlled modulation of incident light may also provide a subtle way of regulating disease development in the study of host–pathogen relations after infection.

Metabolic Adaptation in the Manic-Depressive

When the manic-depressive is psychologically disturbed, biogenic amine metabolism[1], adrenal cortical activity[2], the disposition of sodium[3] and the concentration of cyclic AMP in the urine[4] may be modified. During normothymic interva none of these measures of endocrine function fall outside normal limits[1–4]. Occasional and temporary diabetic-like responses to a glucose tolerance test appear, however, not only during episodes of depression and mania, but also during asymptomatic periods, despite an adequate carbohydrate intake and with no discernible impact on affect[5]. If, as we have suggested[6], manic–depressives have a defect in the regulation of hormonal balance, an environmentally induced perturbation might make the difficulty apparent even when they are normothymic and their response to a glucose load is normal.

In a healthy man, fasting provokes changes in hormone balance[7] and, probably, changes in the activities of a number of adaptive enzymes[8]. The response to a glucose load is diabetic-like in contrast to the normal response before the fast. A group of manic–depressives was therefore subjected to this simple and reasonably innocuous test of their abilit to reorganise their hormonal balance when faced with a environmental demand for such a change.

Sixteen males volunteered for a 3 d fast. All had glucose tolerances that were non-diabetic as defined by the US Public Health Service[9]. Six were staff members, five were manic–depressives who were normothymic at the time of the experiment, and five were schizo–affectives. The latter groups were being treated with lithium carbonate and were selected from a population whose metabolic and psychological states had been followed for at least 3 yr. Diagnoses were based on the presence of the following symptoms: manic states—hyperactivity, flight of ideas, pressure of speech, elated or irritable mood; depressed states—motor retardation, poverty of thought, depressed mood; schizo–affectives—disintegrated thought and affect and concomitant changes in mood. All of the manic–depressives had a history of at least three manic episodes and two depressed episodes. All of the schizo–

Table 1 Experimental Protocol

Days 1–3	Diet containing at least 250 g carbohydrate. No food after 2200 h on day 3.
Day 4	Pre-fast GTT*—Oral test starting at 0800 h. (Blood samples were collected in the fasting state, then 0.5, 1, 2, and 3 h after drinking a solution containing 75 g of glucose.) No food for remainder of day.
Days 5–6	Fast.
Day 7	Fast GTT*—Repeat oral test starting at 0800 h, then diet containing at least 250 g carbohydrate.
Days 8–9	Diet containing at least 250 g carbohydrate. No food after 2200 h on day 9.
Day 10	Refeed GTT*—Repeat oral test starting at 0800 h.

* GTT—Glucose tolerance test.

‡ Patient took test twice: once after he had discontinued lithium carbonate treatment for approximately 3 months; once after he had resumed lithium carbonate treatment for 1 month.

affectives had a history of at least five episodes of mania, hypomania or depression.

The experimental procedure is outlined in Table 1. Participants who had been taking lithium carbonate before the experiment continued their medication in the same amounts and on the same schedule during the fast and refeeding periods (Table 2). This design was selected since several patients were reluctant to discontinue lithium therapy. One patient (LD) was tested with and without lithium. No significant affective changes took place in any of the participants during the experiment.

Serum glucose was determined by the hexokinase: glucose-6-phosphate dehydrogenase reaction[10]. Serum lithium was measured by atomic absorption spectrophotometry and sodium and potassium with a flame photometer. Serum lithium levels increased during the fast but the decrease in serum sodium and potassium was not significantly different from decreases in controls (Table 3). Urine samples were tested for 'ketone bodies' with a commercial preparation that contains sodium nitroprusside and detects acetoacetic acid at a level of 5 mg per 100 ml. A positive reaction appeared on day 6 in all cases and became intense by day 8. No reaction was detected on days 4 or 10.

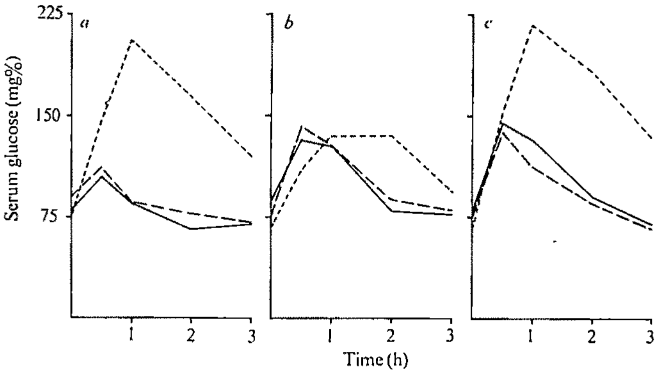

Fig. 1 Effects of fasting on the response to a glucose load. ——, Pre-fast; - - -, fast; — — —, refeed. *a*, Control; *b*, manic–depressive; *c*, schizo–affective.

The results of the glucose tolerance tests are shown in Fig. 1 and Table 4 and, in the case of LD, in Fig. 2. The fast produced notable differences between manic–depressives and the other groups. First, the response to the glucose load, as measured by the sum of the five sampling periods, was lowest in manic–depressives and only slightly higher than their pre-fast levels (36 mg%) while this sum was increased by 306 mg% in the non-medicated group and by 240 mg% in the medicated controls. Second, the half-hour serum glucose levels of the manic–depressives were lower than their comparable pre-fast or refed levels by almost 20%. This contrasts with the relatively higher levels in the controls (35%) and the schizo–affectives (10%) at this time. Third, the manic–depressives showed some adaptation to the fast. Peak glucose levels occurred late (2 h) and levels at this time were higher than in the pre-fast or refed tests. The response, however, was comparatively moderate as well as delayed.

The pre-fast and refed glucose tolerance curves of the schizo–affectives and manic–depressives were somewhat elevated compared to controls. This is consistent with the reports of a higher incidence of diabetic-like responses among manic–depressives[5] and in patients subjected to long term phenothiazine treatment[11], which was the case with the schizo–affectives. Nonetheless, the schizo–affectives reacted

§ Schizo–affectives compared to controls.

to the fast like the controls.

Though we have not yet found a sufficient number of non-medicated volunteers to establish this with certainty, lithium does not seem to be a critical variable in these experiments. The response of the two lithium groups to the fast was different in spite of the similarity between their pre-fast and refed glucose tolerance curves. The lithium control group responded to the fast like the non-lithium controls. LD's curves were virtually identical with or without lithium.

In further investigations of the glucose metabolism of the manic–depressive, we have noted that the serum insulin levels do not always correlate with the response to a glucose load. While these preliminary data are consistent with a change in overall hormonal balance rather than a change in any single hormone, the complexity of the neuroendocrine system presents problems in the identification of the critical difficulty. Hormonally-mediated responses involve synergistic and antagonistic effects on rate-limiting cellular processes[12], feedback regulation of hormone levels[13], influences on gene expression[14] and protein synthesis[15] and a critical role of the central nervous system in the organisation of these events[16]. Glucose metabolism itself is influenced by insulin, glucagon, catecholamines, glucocorticoids, thyroid and growth hormone[17].

Further, Britten and Davidson[18] have suggested that the expression of mammalian regulatory genes[19] is under hormonal control. A defective regulatory gene could account for the unusual response of the manic–depressive to a fast and still permit successful and appropriate responses to the many stimuli which continuously provoke changes in hormone balance. Since long-lasting modifications in gene expression can be environmentally induced[20,21], such a defect in function does not necessarily imply a mutation.

Whatever the origin of the unusual response to the fast, it appears that the manic–depressive is at risk biologically, a view which finds support in the report of the premonitory changes in noradrenaline metabolism in manic attacks[22] and the failure to discover immediate precipitating psychological causes for the sudden appearance of a disordered affect[23]. It is also apparent that susceptibility to severe affective episodes occurs in individuals with very different biochemical characteristics, a fact which may be of value in diagnosis. Whether the hormonal disturbances associated with a disordered affect in manic–depressives and schizo–affectives are identical or whether differences occur here also is now subject of investigation in this laboratory.

book reviews

Newton's *Principia Mathematica*

Philosophiae Naturalis Principia Mathematica. By Isaac Newton. Third edition with variant readings. Edited by Alexandre Koyré and I. Bernard Cohen, with Ann Whitman. Vol. 1 pp. 547; vol. 2 pp. 368 (Cambridge University: London, August 1972.) £25.

ntroduction to Newton's Principia. By I. Bernard Cohen. Pp. 380. (Cambridge University: London, October 1971.) £13.

NEWTON'S *hypotheses non fingo* is almost as well known as his experiments with the prism or his observation of the falling apple. But its meaning is not so clear. Not that the eighteenth and nineteenth centuries were in much doubt about it. In English it meant "I frame no hypotheses" in the words of Andrew Motte's English translation of the third edition of the *Principia*, and in French it meant the slightly different "J'imagine point d'hypotheses" in the words of Voltaire's friend Emilie du Châtelet's posthumous French translation. For almost everyone—especially scientists—it meant facts are safe, hypotheses dangerous, hold to the former, avoid the latter and, in so far as you do that, you will be following the immortal Newton's advice and the success—if not the importance—of your enterprise will be guaranteed.

Newton's practice, however, did not always square too well with this advice. Admittedly, there are no very obvious hypotheses in his first optical paper of 1672, that supreme example of the art of drawing deductions from experiments. But what of the paper of 1675, "An hypothesis explaining the properties of light . . .", with its fantastical explanation of reflection and refraction in terms of an hypothetical ether whose pressure was greater in air than in solid matter, and to which was later joined an *ad hoc* hypothetical "skin" at the inter-surface between air and solid, not to speak of "easy fits" of transmission and reflection to explain partial reflection and the colours of soap bubbles and of Newton's "rings". Newton was evidently prepared to "entertain" hypotheses, even if he did not "frame" them, and even if he only entertained them for the sake of certain great "virtuosos" whose heads ran "much upon hypotheses".

But what of the *Principia* itself, that arc of the scientific covenant? Even if we suspend judgment on the charge of an hypothetical element in concepts such as force, mass or gravitational attraction with their inextricable mixture of the actual and the ideal, it is impossible to deny the existence of no less than eight named hypotheses at the beginning of Book 3 of the first edition. But in this edition the *hypotheses non fingo* is absent; it appears first in the famous concluding *Scholium Generale* of the second edition. In that edition the number of named hypotheses is reduced from eight to one. In other words, a comparison between the first and second editions of the *Principia* indicates a considerable hardening in Newton's attitude to hypotheses. So that whatever he actually meant by *hypotheses non fingo* in 1713 it is not likely to have been exactly the same as what he would have meant by the same phrase in 1687.

This discovery, made independently by I. B. Cohen and the late Alexandre Koyré, had two important effects: it led to a fundamental reappraisal of Newton's attitude to hypotheses, and to the suggestion by Koyré—since generally accepted—that what Newton really meant by *hypotheses non fingo* was not "I do not frame hypotheses", but "I do not feign hypotheses"—in the manner of Descartes, for example. In the second place, this discovery led to the realisation that Newton's thought did not suddenly become static after the publication of the *Principia* in 1687, and that the various editions of the *Principia* contained a great deal of evidence—hitherto largely ignored—on his changing attitudes to certain key concepts including that of hypotheses. Like some of the best discoveries this one is inclined to seem obvious in retrospect. But it fired Koyré and Cohen to undertake an enterprise of heroic proportions, a variorum edition of the *Principia.*

Of the variorum edition itself I do not propose to say much beyond praising its admirable plan, its beautiful printing and layout, and its excellent critical apparatus. The edition is based on a total of eight texts, those of the three editions, the printers' copy of the first edition, and the four interleaved copies —two each for the first and second editions—kept by Newton himself for the noting of errors and improvements. The level of accuracy attained in such a work is evidently of cardinal importance. This is something which can only be determined by use over a long period. I have no doubt it will be found to measure up to the most exacting standards.

The accompanying introduction by I. Bernard Cohen is mostly taken up with the history of the preparation of, and reaction to, the three editions of the *Principia.* Of this history a great part is devoted to the story of the long and gradual process of correction and emendation by which the first edition of 1687 was transformed into the greatly improved second edition of 1713 from which the third edition of 1726 differed little. Apart from Newton himself, pursuing the endless task of correction with unswerving and unhurried determination, there appear a number of other figures. Halley, who had played such a large part both in the composition and publication of the first edition, and who wrote the first review of it. The Italian Fatio De Duiller to whom Newton seems to have been powerfully attracted for a time before his scientific judgment reasserted itself, and whose notes on the *Principia* are interesting not for their intrinsic merit, but for what they tell us of the early stages in the preparation of the second edition. David Gregory, who made a more intensive study of the *Principia* than anyone apart from Halley and Newton himself, but who was disappointed in his plan to publish a commentary, or possibly even in becoming editor of the second edition. Richard Bentley, under whose masterful hand the printing of the second edition was actually begun in 1708, only to be discontinued after eight pages, probably because Newton suddenly realised that Bentley's mathematical inadequacies would have necessitated his checking all the proofs himself.

Finally, the somewhat tragic figure of Roger Cotes, Plumian professor of mathematics at Cambridge, who had the necessary mathematical ability, the tact not to offend Newton, and the strength of character to stand firm against him when he knew he was in the right and Newton in the wrong. As the Newton-Cotes correspondence shows, Newton's debt to Cotes was enormous as regards his overseeing of the printing, his discovery of errors, suggestions for improvements, and provision of the famous preface with its brilliant exposition of the Newtonian philosophy of science including Newton's very subtle attitude to gravitational attraction. Sad to say, as Professor Cohen admits, there is no trace in the Newton-Cotes correspondence of any word of thanks from Newton to Cotes for all his enormous labours: and Newton's famous epitaph to Cotes following his early death in 1716: "If Mr Cotes had lived we might have known something" seems to imply that Newton never fully appreciated Cotes' contribution, since but for Cotes the second edition of the *Principia*, if it had ever appeared, would certainly have been a much less important edition than it actually was.

Throughout almost the whole of the introduction Cohen shows an easy mastery of a vast mass of source material, follows the good example of Newton himself in the matter of English prose style, and strikes a happy balance between an uncritical reproduction of every scrap of relevant information and a too shallow and superficial treatment. Only in chapter 3—"Steps toward the *Principia*"—does he seem to falter a little. One reason for this may have been uncertainty what to say here about the technical, dynamical aspects of the early steps in the composition of the *Principia*, about which an additional volume of commentary is promised. In fact the treatment given is not only confused on occasion, especially in the discussion of the various versions of the tract *de Motu*, but it also contains a number of somewhat hasty judgments which will hardly command universal assent.

Thus it seems to me somewhat improbable that in 1684 Newton was admired by the *cognoscenti* not only for his discoveries in mathematics but also for his "grasp of the fundamentals of dynamics" (page 47); in the first place Newton was very secretive about his early work in the subject, and in the second place "the fundamentals of dynamics" had, in part, still to be formulated. Equally suspect is the assertion (page 52) that Newton "apparently learnt of Kepler's law of areas in 1678 *and at once was able to solve the problem of Keplerian planetary motion*" (my italics). This view, originally put forward by D. T. Whiteside[1], was very improbable *a priori*, and was then effectively ruled out by J. L. Russell's[2] demonstration that Kepler's laws had been much more familiar to astronomers in the first half of the seventeenth century than had previously been thought to be the case—Russell lists four authors, Herigone, Ricciolli, Boullian and Wallis, who all cited Kepler's second law in its exact, areal form before 1660. Admittedly, the second law was evidently the least familiar, and its dynamical significance remained entirely hidden before 1679. But it is stretching credulity to suppose that Newton had not noticed—and deeply pondered on—this extraordinary law before 1679. Curious, too, is the assertion (page 53) that "only near or at the surface of the Earth did he (Galileo) conceive of a true linear inertial motion" or the truly extraordinary remarks (page 61) that the tract *de Motu* "does not yet bear the mark of genius" and contains "no hint of the grandeur of the *Principia* to come": after all, it was in this tract that Newton first solved the problem of Kepler motion, the very cornerstone of the whole *Principia*.

Critics will inevitably differ, as critics do, on these and other minutiae. All will be agreed, however, on the magnitude of the achievement of the variorum edition and its introductory volume. Barring the unlikely appearance of important new Newton manuscripts, the whole work will surely remain definitive well into the next century, if not beyond. Alexandre Koyré, I. B. Cohen and their band of devoted assistants have deserved well of the republic of letters, and I can only regret that Koyré did not live to see the completion of the work originally conceived by him and Cohen in 1956. J. W. Herivel

Rockets and roubles

The Origins and International Economics of Space Exploration. By Bernard Lovell. Pp. viii+104. (Edinburgh University: Edinburgh, 1973.) £1.50.

It is excellent to find such a wealth of information in so slim a volume. I especially enjoyed the succinct and clear historical part (the first quarter of the book). To describe the early military history of the rocket, to disentangle the labours of Tsiolkowsky, Goddard and Oberth, to demonstrate the independence of Soviet work from the earlier German efforts, to explain the administrative tangles in the United States before NASA got going, and all in some twenty very readable pages is most valuable. Much of the rest of the book gives data on costs and on numbers of launchings, and examines the relative sizes of civil and military space efforts in both United States and Soviet Union all in very convenient and easily assimilable form, and describes briefly, and perhaps a bit conventionally, the various benefits of space activity. Science in particular is dealt with too briefly for anybody to learn much from it, but more justice is done to the applications. The contrast of the cost of manned and unmanned space activities is well brought out, and a somewhat implicit admiration, richly deserved, for the political vision, superb decision taking, and technological brilliance of the Apollo programme is understandably followed by a much more dubious attitude to later manned activities (Skylab and Shuttle) to which so much highly promising space science (high energy astronomy and planetary observation) is being sacrificed.

However much I admire these concise descriptions, I am distinctly less thrilled by Sir Bernard Lovell's more philosophical comments, comments that are far too brief and therefore lack clarity and depth. If there was not the room to develop the argument more fully (which might well have been fascinating), then the commentary should have been left out. As it is, the reader is simply confused and irritated by the sputtering that first points one way, then the other, never addressing itself to any problem for long enough, never resolving the contradictions.

To give some examples: after soberly describing the V1 and V2 campaigns, and the casualties caused, he rightly says that these weapons could have affected the war far more but for the bombing of Peenemunde, only to be "filled with dismay and an unresolved conflict" by the thought that this bombing was made possible by the blind bombing aid which he had helped to develop "illuminating for destruction the genesis of one of the greatest scientific developments of all time . . .". His dismay is hard to understand, given the facts of the situation. Similarly, on page 86 he stresses that the United Kingdom's space expenditure was so minute that, if transferred to education, health and social security, it would have hardly made any difference, but on page 87 he speaks of wasting "these extremely large sums" (that is, those applied to space, perhaps including this time the other European countries). Whether depending on the United States for launching rockets (page 87) is the bad thing it is implied to be at least deserves to be debated. I, too, am keen on space, but would find it hard to sustain (though I would enjoy reading a good argument on the issue) the assertion that "many of the urgent problems associated with the predicted doubling of the world's population can be alleviated by space applications" (page 88). These are important and controversial issues on which reasoned argument would have been most welcome, but little benefit is derived from over-brief and often unclear assertions.

But my gripe about what is not in the book should not cloud my advice to all interested in space to read it for its factual content. H. Bondi

Food and development

The Nutrition Factor: A Study jointly by the Foundation for Child Development and the Brookings Institution. By Alan Berg. Portions with Robert J. Muscat. Pp. xii+299. (Brookings Institution: Washington DC; Allen and Unwin: London, August 1973.) £4.50 boards; £1.75 paper.

THIS is a worthwhile book. It is concerned with the improvement of nutritional health in the developing countries but differs from most other books on the subject in that it goes to great length to point out that such improvements have an important role in national development. This is not a practical manual in that it does not set out step-by-step instructions—the approach is not so dogmatic; rather it deals in a philosophical way with the background to the problem and suggests principles for effecting change. The book will surely become essential reading for students of applied nutrition and for those administrators and civil servants in the developing countries who have need to convince their rulers that the malnourished members of the community are not economically insignificant.

The starting point of Dr Berg's philosophy is best summed up in his own words: "malnutrition adversely affects mental development, physical development, productivity, the span of working years—all of which significantly influence the economic potential of man". It would be easy to quibble with the opening chapters in which Dr Berg justifies this statement. Perhaps too little theoretical proof is available but few scientists or doctors would doubt its basic truth, and the aim of the book is to encourage national action rather than stimulate further fundamental research.

A whole chapter is devoted to the cynical but often encountered argument that improved nutrition will merely exacerbate the population problem. The nutritional adviser will need to combat this line of attack; the chapter provides some valuable ammunition. People in developing countries will not readily accept contraception until they can be sure that their children, in particular sons, will survive.

Dr Berg quite rightly believes that significant nutritional improvements at a community level will materialise only if the problem is viewed from a national perspective and tackled by broadly based preventive measures. He points out the limitations of the "person to person diagnostic and curative approach"; however essential this may be to the ministries of health, national planners need to adopt a more comprehensive policy. The main possibilities discussed are: economic growth leading to higher incomes and hence better nutrition, improved agricultural production and farming technology, nutritional education, the formulation of new foods and nutrient fortification, the encouragement of new food industries and, finally, feeding children through nationally organised public programmes. Each topic is dealt with and commented on in an instructive manner. The conclusion is that each approach has its valuable features but none can achieve the desired goal alone; an integrated plan is essential.

The main stimulus for Dr Berg's approach to malnutrition has been his experience of India, and the narrative ends with a discussion of the lessons learnt there both from the general situation and from the crisis brought about by the Behar famine. Dr Berg considers that the beginnings of a national programme in India can be looked upon as a prototype by other nations.

The book concludes with numerous tables and appendices providing valuable facts and figures together with a comprehensive bibliography.

This monograph purposefully confines itself to the food and dietary factors involved in malnutrition and readers might, if they did not read carefully the penultimate paragraph of the first chapter, be led to believe that these were the only ones that matter. Perhaps it is of value to dispel this idea by again quoting Dr Berg: "In a systematically planned search for remedies to nutritional problems, many non-standard nutritional measures will be considered. Protected water supplies, waste disposal and other forms of environmental sanitation, immunisation against certain diseases, for instance, all relate to the incidence of malnutrition, its relative severity and the reduction of mortality. Although such measures are not normally thought of as nutritional measures, they may be significant determinants of nutritional status, or, more likely, essential in combination with the food-related measures that this study focuses on".

These words emphasise still further the enormity of the problem facing those who are trying to improve nutritional health in the developing world. Little wonder Dr Berg advocates such far-reaching preventive measures; his book is timely and warmly welcomed.

R. G. WHITEHEAD

Solid state electrochemistry

Electrochemistry of Metals and Semiconductors: The Application of Solid State Science to Electrochemical Phenomena. By Ashok K. Vijh. Pp. xiv+297. (Dekker: New York, May 1973.) $23.50.

THE electrode-solution interface has been studied from the viewpoint of solid state physics by many workers since the pioneer paper of Grimley and Mott in the 1947 Faraday Discussion. During these years the theory of redox reactions at metal or semiconductor electrodes has been developed by Gerischer on the basis of the classical hydrogen overvoltage paper of R. W. Gurney; a good many practical applications have been examined, and some established in industry. Dr Vijh works in the Hydro-Québec Institute of Research, and has published a number of papers in recent years. His book sets out to provide first a rudimentary introduction to the solid state (really band theory) to electrochemists unfamiliar with this topic. There follow eight chapters, including three on electrode reactions (general principles, elemental semiconductors, bulk compound semiconductors), then anodic oxidation of metals and non metals, and the effect of surface films on electrode reactions. In chapter 7 the solid state properties of metals are related to their electrochemical behaviour, and in chapter 8 electrochemistry in the solid state (as solid electrolytes and proton conduction in ice, and so on) is studied. A final chapter deals with industrial aspects, some ten applications being noted from fuel cells and batteries to mineral processing.

Most of my criticisms turn on points of detail, since the book as a whole usefully fills an important gap in the monographic literature. To say that semiconductors show a non-Ohmic behaviour under ordinary conditions (p. 21) is surely rather misleading. In view of its importance more attention should have been given to explaining the Fermi level, and its relation to energy bands and impurity levels. The printing of the various Galvani potentials on p. 191 *et seq.* leaves much to be desired. On p. 21 intrinsic conductivity is rightly written as $\sigma_0\ \exp\text{-}(E_g/2kT)$, on p. 131 wrongly as $\sigma_0\ \exp\text{-}(E_g/kT)$. There is published evidence for the free energy of activation for oxide growth proportional to the oxide thickness (p. 132) but this is not quoted.

Putting such detailed matters on one side, the book is easy to read, and should perform a valuable function in introducing research workers to an important new field of interfacial activity, and we may expect it to stimulate further efforts in this direction. Biological systems are rightly excluded from the present volume, but there are also signs of a growing activity in this area.

D. D. ELEY

Animal chromosomes

Animal Cytology and Evolution. By M. J. D. White. Third edition. Pp. viii+961. (Cambridge University: London, June 1973.) £19; $55.

WRITERS of general accounts of chromosomes before Professor White used to attempt to cover both plants and animals. This policy was justified by the uniformity in principle and also by the complementarity in detail of the two kingdoms: the chromosomes of plants were more useful in showing the causes of evolution; those of animals revealed above all its consequences. Or, to put it in another way, the immense range of experiments, chemical and physical, genetic and physiological, that have been successful with plant chromosomes provide quite a different picture from the descriptive variety which is revealed by a systematic survey of animal chromosomes.

Professor White was the first, in successive editions of this book, to try to disentangle the animals from the plants, the consequences from the causes. He took this course, no doubt, because the animals suited him extremely well. He is the most experienced specialist in animal cytology in the world and he excels in describing and illustrating the wealth of variation of chromosomes in their form and behaviour as they operate the multifarious genetic and developmental systems of animals.

Naturally Professor White has to refer to the principles of chromosome behaviour revealed by plants, but he does so reluctantly and piecemeal, lightly suspending his judgment whenever the issue becomes serious. Evidently he does not recognise the contrast or the complementarity between the opposed evolutionary aspects of chromosome study, and no one from reading this book could pick up any such disturbing notions. There are many students of chromosomes, to be sure, who will not want to be disturbed, and for them Professor White has provided a solid and satisfactory work of reference.

C. D. DARLINGTON

Scottish shores

The Coastline of Scotland. By J. A. Steers. Pp. xx+335 (64 plates). (Cambridge University: London, 1973.) £10.50; $31.50.

IT is now almost thirty years since Professor Steers's monumental work on the coastline of England and Wales appeared. The natural sequel was a similar study of the coasts of Scotland and now, in retirement, he has, with characteristic thoroughness, set out his views on the form and origin of some of the finest coastal scenery in Britain. The book is cast in much the same mould as his earlier work with a few introductory chapters covering general themes to be followed by a survey of the whole coastline, including all the offshore islands. Inevitably he has drawn heavily on the work of others, for although he has walked over nearly all the coastline he describes, detailed studies of individual sections proved impossible.

Fortunately the geological memoirs of Scotland are particularly detailed as regards coastal sections and many of the early volumes, like that of Caithness, contain a wealth of physiographic information. There is, however, a general lack of research papers similar to those found in the local journals in England. In part this deficiency has been made good by the research efforts of Scottish geographers, particularly those based at Aberdeen. Professor Steers has used their studies to advantage in his text to provide local colour for what is basically a factual account.

Undoubtedly the book will prove of great value to the specialist but seems hardly likely to make easy reading for the amateur enthusiast with an interest in our coastal setting. It is to be regretted that Professor Steers has not felt able to draw upon his vast experience to be more speculative, not only posing problems but giving a lead as to their solution. For the island of Ailsa Craig, for example, he contents himself with a factual account of its geology and vegetation (pages 103–4) without real reference to the interesting ness feature which dominates its eastern coastline. Again in the entrance to Inverness Firth he makes detailed reference to the classic work of Ogilvie, carried out over fifty years ago, when the relative roles of tidal currents and wave action were appreciated for the first time. Since then much new evidence has been forthcoming on this important aspect of coastal evolution, particularly in relation to sediment transport by residual water movements. This is a theme which Professor Steers could have properly developed without recourse to detailed research, for the evidence is there in the bottom configuration of the firth.

The book is well illustrated with maps. It has a centre spread of excellent photographs from the Cambridge University collection of air views, although as they do not occupy the full page size they give the book an old fashioned appearance. Inevitably a comparison will be made with his earlier book on the coastline of England and Wales. It is a sad fact that as book prices have risen steeply in the last few years the quality of production has declined.

A. H. W. ROBINSON

Sea urchin development

Development Biology of the Sea Urchin Embryo. By Giovanni Giudice. Pp. x+469. (Academic (Harcourt Brace Jovanovich): New York and London, August 1973.) $32.

THERE is a great need for more sympathetic communication between experimental embryologists and molecular biologists; and this book, by drawing together the enormous amount of information on the morphogenesis, ultrastructure, biochemistry and molecular biology of the sea urchin embryo, makes a timely and scholarly contribution towards this end.

For the reader with no formal background in embryology there is a lucid account of the experiments of the early 1900s that still provide the basis of current ideas about the programming of sea urchin development; for example, the proposed existence of gradients of potentiality to form ectodermal or endodermal structures emanating from the 'animal' and 'vegetal' poles of the egg respectively. There is fascinating reading, too, in the descriptions of sperm penetration, the behaviour of the male and female pronuclei, and the membrane changes following fertilisation—examples of phenomena which, as yet, have no molecular explanation.

The reasonably up to date summary of research on the sea urchin embryo from a more biochemical viewpoint contains a clear description of experiments which led to such ideas as th existence of 'masked' maternal messenger RNA, and the synthesis of large amounts of histone and histone messenger RNA by the early blastula. But this is a rapidly moving field and it is a pity that the book was finished (early 1972) before the application to the sea urchin embryo of important new advances in the technology of isolating and translating messenger RNAs (see, for example, *Nature*, **245**, 8; 1973) could be included.

Dr Giudice's book is also a useful source of practical information about handling embryos, separating cells, problems of permeability, and so on. It is clearly written, with paragraphs summarising the main problems to be solved and the information available. Beyond this synthesis, however, the author makes no attempts to provide new insights or theories. Finally, the reader is left in no doubt as to the disadvantages, as well as the advantages, of the sea urchin in studying problems of developmental biology, for Dr Giudice is no slavish devotee of his research material. The main disadvantage is, of course, that no genetic analysis of development can be made because it is very difficult to rear the embryos in the laboratory beyond the pluteus stage.

BRIGID HOGAN

matters arising

Douc Langurs

SIR,—Relevant to Dr Kavanagh's observations (*Nature*, **239**, 406; 1972) of food sharing among captive douc langurs (*Pygathrix nemaeus*), I should like to describe some of my own observations of these monkeys in the wild. Between May 1967 and May 1968, I made fourteen visits to Mount Son Tra (elevation 96 m above sea level), about 10 km north of Da Nang on the northeast coast of South Viet Nam. Here I watched two groups of douc langurs as they fed in the canopies of the trees which they inhabited. At the time the animals were relatively tame, benefiting from partial protection afforded by being on a military base, but recently they have declined on Son Tra (Van Peenan *et al.*, *Mammalia*, **35**, 127; 1971). The first groups consisted of four adults, apparently one male and three females (distinguishable when external genitalia were visible), and a baby. The second group consisted of five adults (apparently two males and three females), a half-grown monkey and a baby. The members of a group foraged in close proximity, usually within 10 m of each other, although not always in the same tree, and they rarely came to the ground. Often two or three animals fed in the same terminal clump of foliage, and occasionally when one pulled down a branch, an adjacent individual also fed on it. This type of passive food sharing was noted by Kavanagh.

I also observed active food sharing on two occasions. In the first group of langurs an adult female bit a small section of leafy twig and passed it to the male who quickly stripped off and ate the leaves. The two animals continued to forage within 2 m of each other, but no further interaction was noted for about 30 min. Then, however, the female solicited copulation from the male who subsequently mounted her, but the animals were disturbed by a passing vehicle before intromission was achieved, and they disappeared from view. In the second group I saw a similar case of food being passed from an individual of unknown sex to a female who had a baby clinging to her. I observed no further interaction between these two animals in the few minutes before they disappeared in the foliage.

In each case the passing of food seemed to be spontaneous. The recipient did not appear to threaten or beg, although as Kavanagh pointed out there may be subtle communication patterns inapparent to the human observer. Further observations of these animals in the wild may reveal, as Kavanagh suspected, that food sharing is not rare in family groups in natural conditions. I should add that the species is endemic to the Indochina Region, including Hainan Island, where much of its environment has suffered profound changes, and it is considered an endangered species[1].

Yours faithfully,

MICHAEL GOCHFELD

Division of Environmental Health Sciences,

obituary

Frederick James Dent

FREDERICK JAMES DENT, FRS, OBE, leader of the 1971 MacRoberts Award winning team, died on October 5 at his home in Malta after a short illness. He was 67.

Dr Dent was born in 1905 and was educated at the Modern School, Leeds. He was a student at the University of Leeds under Professor J. W. Cobb, CBE, obtaining his doctorate in 1929 for an original piece of work on the carbon steam reaction. In the same year he was appointed research chemist in charge of gas production investigations carried out by the Joint Research Committee of the Institution of Gas Engineers and the University of Leeds. In this period he conducted a classical study of the water gas process on the full scale which led to a detailed laboratory investigation of the gasification of coal in steam and oxygen at high pressure.

It was during this latter work in 1937 that he discovered that methane produced during gasification under pressure was formed by the direct action of hydrogen on the coal substance. During this same period he carried out a study of the catalytic synthesis of methane from carbon monoxide and hydrogen and identified and solved the problems associated with the application of this reaction to the production of town gas. Both these discoveries, the one relating to coal hydrogenation and the other to methanation, have currently enormous significance in the work going on today in the United States to counter the growing natural gas shortage by the gasification of coal to methane as a substitute for natural gas.

On the day of his funeral the successful start-up of a methanation demonstration plant at the coal gasification plant of Scottish Gas, at Westfield, was announced in the press. The previous week this plant, the essential features of which are directly based on Dent's work, produced the first substitute natural gas from coal on a commercial scale, forerunning new plants in the United States which will produce billions of cubic feet of synthetic natural gas per day in the future. The new generation of processes now being developed in the United States for the production of substitute natural gas will practically all also incorporate the coal hydrogenation reaction which he discovered at Leeds and first demonstrated on a pilot plant scale at the Poole Research Station of the Gas Research Board .

It was at Poole, where he was Assistant Director of the Gas Research Board from 1943–51, that many of Dent's studies on gas production processes, both paper and experimental, were initiated. For example, it was here that the first coal and oil were hydrogenated in fluidised beds and methanol was first catalytically gasified. It was not until he was appointed Director of the Gas Council's Midlands Research Station in 1951, however, that the funds needed to enable him to develop his ideas to commercial reality became available.

The move to Birmingham and later to Solihull coincided with the start of a change in the fuel situation and a shift in emphasis from coal to oil as a feedstock for gas production. The work on the hydrogenation of oil to gaseous hydrocarbon—rich gas accelerated with the construction of a large fluidised bed hydrogenation pilot plant, followed later by two more specially designed ones which led to the development of the Gas Recycle Hydrogenerator. This process, designed specifically to hydrogenate distillate oils, was quickly adopted by the industry and more than fifty units were installed in this country and abroad for the enrichment of over one billion (10^9) cubic feet per day of town gas.

At the same time, he pursued the development of the Catalytic Rich Gas (CRG) process and, with a highly effective catalyst, brought this also successfully to the commercial stage. Some forty-four units of CRG-based town gas plants have been built, ten of them abroad, while more recently two streams of CRG-based substitute natural gas plants have been commissioned in the United States with a further nine streams in various stages of construction. A further plant is shortly to start up in Japan. The combined thermal output of all these plants, some of which are the biggest in the world, matches the size of the present British gas industry.

During this period of intense activity on oil processes, Dent found time to extend the development of the Lurgi fixed bed high pressure coal gasifier to slagging operation. Two pilot plants were built and operated in the late 1950s and early 1960s and the world's first high pressure steam and oxygen slagging gasifier was satisfactorily developed and demonstrated at Solihull to prove the potential advantages which Dent had predicted for this system from his earlier laboratory studies at Leeds. Increasing interest is currently being shown in this gasifier by companies and government agencies concerned with coal gasification in the United States.

Dent's outstanding contributions to the development of processes for the gasification of coal and oil received worldwide acclaim. His work was recognised by the award of the Birmingham Medal (the highest award of the Institution of Gas Engineers) the Melchett Medal of the Institute of Fuel, the Walton Clark Medal of the Franklin Institute of Philadelphia and the Coal Science Medal of the British Coal Utilisation Research Association. He was awarded an OBE in 1958 and was elected a Fellow of the Royal Society in 1967. These honours culminated in 1971 with the engineering profession's highest prize, the MacRobert Award, which he received jointly with the chief members of his team.

His success stemmed perhaps mostly from his ability to interpret his creative scientific work into practical chemical engineering and process technology. His unbounded enthusiasm and the real enjoyment he had in his work, however, produced the drive in others which was essential to the rate of progress he achieved, a factor which he always generously recognised. He was modest to a fault, impatient with the less well informed and demanded complete technical integrity. Amongst those with a common interest in gasification and gas production processes he made many friends who will retain a memory of a cheerful and kindly man with a deep and detailed understanding of both the theoretical and practical aspects of his subject.

He leaves a widow, a son, a daughter and three grandsons.

Announcements

Appointments

Professor A. D. Bradshaw is to be chairman of the **Nature Conservancy Council's** advisory committee on science.

Derek A. Ratcliffe has been appointed Chief Scientist of the **Nature Conservancy** and **Ian Prestt** is to be Deputy Director.

Professor W. A. Holmes-Walker has been appointed Director of the **British Plastics Federation.**

Harry Hookway, Chief Executive and Deputy Chairman of the **British Library** has been elected President of the Institute of Information Scientists.

Joan Eileen Walsh has been appointed to be Professor of Numerical Analysis of the **University of Manchester.**

Miscellaneous

The Lomonosov Gold Medals for 1973 have been awarded to **Academician Aleksandr Pavlovich Vinogradov** for his work in geochemistry and to **Vladimir Zoubek** for his work in geology.

The Council of Systematics Association Department of Biology plan to offer an Essay Prize in 1974.

Erratum

In the article "Pharmacologically induced behavioural supersensitivity to apomorphine" by Daniel Tarsey and Ross J. Baldessarini (*Nature new Biol.*, **245**, 262; 1973) the following sentence should be added. "Dr Tarsy is a member of the Department of Neurology, Boston University School of Medicine and the Boston Veterans Administration Hospital, Boston, Massachusetts".

When you need to know enzymes Miles can help!

We at the Research Division are big enough to supply your enzyme requirements in kilogram quantities. But we are small enough to handle micrograms for the most sophisticated researcher. Our catalogs, with over 150 enzymes and purity variations, are complete with assay methodology and detailed specifications. Our introduction of ENZITE®, the first immobilized enzymes, is only one example of our commitment to filling your needs and our continuing two-way dialog with the research community. We cannot catalog the answer to every question so we have people around the world to aid you. If you have a problem or question just call or write to the office nearest you for personalized assistance. We are here because no problem is small enough until it has been solved.

Flammability Testing.

The new Stanton FTA Flammability Test equipment is designed for easy use, gives accuracy to 0.1%, of critical oxygen index conforms to ASTM D-2863, and has many applications in work on Textiles, Wood, Floor Coverings, Plastics, Protective Clothing, etc.

Special features include:
Direct reading of critical oxygen index.
Direct observation of burning profile and spread of flame.
Capability for after-glow and heat-evaluation determinations.

Full details from:
Stanton Redcroft,
Copper Mill Lane, London SW17 0BN.

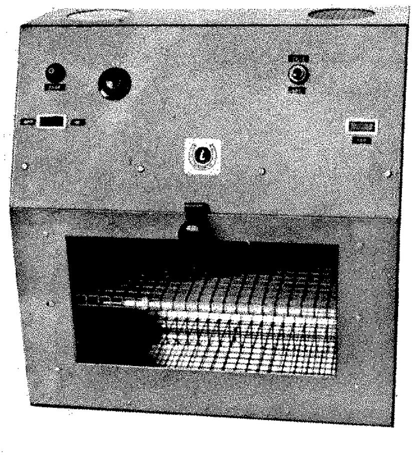
what's the difference between these cabinets?



◄ This is the Luckham drying cabinet SD/350/I model which has many uses but designed primarily for the Histologist for the quick drying of paraffin sections and for carrying out 'hot' staining techniques. The air temperature can be used at ambient or between the range of 50°–60°C. The shelves are made of wire mesh to allow complete air circulation and quick drying.

This is the SD/350/2 model. Basically it looks the same as the other model, but it has been specially developed as an incubator as well as for drying autoradiographs and films etc. The heat range can be controlled from ambient and from 30°–60°C. Both models have a removable centre shelf so that various sizes of racks, jars or pots can be accommodated. ►

APPOINTMENTS VACANT

MONASH UNIVERSITY

MELBOURNE, AUSTRALIA

DEPARTMENT OF MATHEMATICS

LECTURER IN MATHEMATICAL STATISTICS

Applications are invited for a position of Lecturer in the Statistics Section of the Mathematics Department.

The Statistics Section has 15 members of staff whose interests include aspects of stochastic processes, multivariate analysis, foundations of statistical inference, mathematical genetics, decision theory, measure theory. The section is also the focus of a biomathematics programme.

Salary scale: $A8,698 to $A11,982 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5 per cent and 10 per cent respectively.

Benefits: Travelling expenses for the appointee and family; removal allowance, repatriation after three years' appointment if desired; temporary housing for an initial period; study leave entitlement accumulates at the rate of one month's leave for each six months' rvice up to six years, with provision for financial sistance.

Further general information and details of the plication procedure are available from the Academic egistrar, Monash University, Wellington Road, Clayton, Victoria, 3168 Australia, or the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. Enquiries about the Department may be directed to Professor J. S. Maritz, in the University. Applicants should quote reference no. 40112.

Closing date: **January 31, 1974.**

The University reserves the right to make no appointment or to appoint by invitation.

(198)

ROYAL POSTGRADUATE MEDICAL SCHOOL

HAMMERSMITH HOSPITAL

Applications are invited for the following posts:

1. GRADUATE BIOCHEMIST

To join group studying inborn errors of organic acid metabolism. Duties will involve measuring enzymes of Acyl CoA interconversions and responsibility for the development of new assays suitable for use with cell preparations from affected children. Salary range £1,812 to £2,448 per annum. Ref. 2/141/N.

2. GRADUATE IN BIOLOGICAL SCIENCES

Required for work relating to the diagnosis of cancer by radioisotope scanning. Duties involve care of small colony of rats and mice and assistance with experimental work. Some experience of animal work an advantage. Starting salary up to £2,025 per annum. Ref. 12/230/N.

3. JUNIOR TECHNICIAN

Required in Clinical Immunology Laboratory interested in the mechanisms of inflammation. Previous experience of immunological techniques an advantage. Qualifications: "O" level passes in English, Maths and 2 Science subjects. Salary in range £840 to £1,575 per annum according to age and qualifications. Ref. 2/143/N.

4. JUNIOR TECHNICIAN/TECHNICIAN

Required for research work on venous thrombosis and rheumatoid arthritis. Experience of haematological techniques and animal work an advantage. Minimum qualifications "O" level passes in English, Maths and 2 Science subjects. (Salary scale £840 to £1,575 per annum.) Candidates with AIMLT/HNC will be graded as Technician (£1,578 to £1,794 per annum). Ref. 3/226/N.

Applications to the Secretary, R.P.M.S., Hammersmith Hospital, DuCane Road, London W12 0HS, quoting the appropriate reference. (229)

ICI Pharmaceuticals Division

Biochemists

The Pharmaceuticals Division of Imperial Chemical Industries Limited invites applications from biochemists for two research posts at the Alderley Park Research Laboratories. One post is concerned with the relationship between cardiac metabolism and the contractile performance of the heart, and the other with the biochemical and endocrinological mechanisms involved in the control of tissue growth and nitrogen balance in health and disease.

Applicants should have a Ph.D. or expect to receive it during 1974. While appropriate research experience would be useful, a willingness to apply biochemical research to the discovery of new and improved drugs is considered more important.

The Pharmaceuticals Division is very attractively situated in rural North Cheshire, within easy reach of main road and rail routes. There is a wide range of country and town housing within 20 minutes' drive to cater for most tastes. Conditions of service, career opportunities, and assistance given to married men in moving home are designed to attract and retain staff of high calibre.

Applications in writing, giving details of age, qualifications and experience should be addressed to:

M. F. Losse, Personnel Officer,
Imperial Chemical Industries Limited,
Pharmaceuticals Division, Mereside, Alderley Park,
Macclesfield, Cheshire SK10 4TG.

(181)

GOVERNMENT OF HONG KONG

SENIOR WATERWORKS CHEMIST (DESALTING)

Required to set up and take charge of a Control Laboratory, or a major seawater desalting installation.

Male candidates under 45 years, MUST have a 1st or 2nd class Honours degree in chemistry from a British University; OR be an Associate Member of the Royal Institute of Chemistry. They must have at least 7 years post-qualification experience including 5 years in a responsible position as Chemist in an electricity generating station, preferably oil-fired. Particular experience of salt and fresh water treatment and examination is desired.

Commencing salary £6,330 to £6,920 a year, approximately. A substantial Gratuity is payable on completion of engagement which is for one tour of 2½ years. Other benefits include free passages, liberal leave on full salary, generous education allowance and government quarters at moderate rental.

For further particulars you should apply giving brief details of experience to:

crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number M3F/731207/NF.

Royal Naval Physiological Laboratory
Alverstoke, Hants

Physiologist

■ Research into body heat exchange problems in underwater environment ■ Work currently directed on temperature gradients in subcutaneous tissues.
☐ 1st/2nd hons degree or equivalent in Physiology ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2076-£2667) or Scientific Officer (£1318-£2177) according to age and experience ☐ Ref: SA/1/FAA ☐ Closing date 1 February 1974.
☐ Application forms from Ministry of Defence (Procurement Executive) SPM1b3 Room 402, Savoy Hill House, Savoy Hill, London WC2R 0BX, telephone 01-836 1207 ext. 1667/1665.

British Museum
Research Laboratory, London

Chemist

■ To examine and develop conservation methods for a wide range of organic objects, particularly library and archival material.
☐ 1st/2nd hons degree or equivalent in Chemistry ☐ At least 2 years' research experience ☐ Interest in bio-deterioration an advantage ☐ Age normally under 30 ☐ Appointment as Higher Scientific Officer (£2251-£2842) ☐ Ref: SB/3/DJA ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

British Museum (Natural History)

Zoologist

■ Curatorial and advisory work in Fish Section ■ Opportunity for taxonomic research.
☐ Degree/HNC or equivalent in Zoology ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2251-£2842) or Scientific Officer (£1493-£2352) according to age and experience ☐ Ref: SB/15/DK ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Ministry of Agriculture, Fisheries and Food
Pest Infestation Control Laboratory, Surrey

Zoologist

■ In Land Pests and Bird Research Department ■ To join team studying the biology and control of harmful birds ■ Initial work on starlings ■ Assist with projects on other species ■ Extensive field work and travel involved.
☐ 1st/2nd hons degree or equivalent in Zoology ☐ At least 2 years' postgraduate experience ☐ Driving ability essential ☐ Age normally under 32 ☐ Appointment as Senior Scientific Officer (£2615-£3640) or Higher Scientific Officer (£2076-£2667) ☐ Ref: SB/6/AF ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext 500 or London 01-839 1992 (24 hour answering service.)

Ministry of Agriculture, Fisheries and Food
Fisheries Experiment Station, Conway, Caerns

Botanist/ Microbiologist

■ In Shellfish Culture Unit ■ Operate existing algal culture systems ■ Investigate food value of novel and existing algae ■ Devise new techniques for large scale culture.
☐ Degree/HNC or equivalent in Botany or Microbiology ☐ Mechanical aptitude an advantage ☐ Age under 27 ☐ Appointment as Scientific Officer (£1318-£2177) ☐ Ref: SB/1/A ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Centre for Overseas Pest Research
London

Plant Diseases Editor (Pans)

■ To work on quarterly journal dealing with tropical crop protection ■ Commission articles from authors ■ Attend Conferences, Meetings and prepare reports ■ Visit commercial companies and research stations for developments in the field.
☐ 1st/2nd hons degree, or equivalent, in appropriate subject which included plant pathology ☐ At least two years' postgraduate experience ☐ Experience in applied plant protection, preferably overseas, an advantage ☐ Age normally under 32 ☐ Appointment as Senior Scientific Officer (£2790-£3815) or Higher Scientific Officer (£2251-£2842) ☐ Ref: SA/8/JA ☐ Closing date 1 February 1974.
☐ Application forms from Administrative Secretary, Centre for Overseas Pest Research, College House, Wrights Lane, London, W8 5SJ.

Ministry of Agriculture, Fisheries and Food
Salmon and Freshwater Fisheries Laboratory,
London

Biologist

■ To join team assessing potential of grass carp for aquatic weed control ■ Help develop new laboratory technique to examine effects of adverse conditions on fish behaviour ■ Field work and variety of other duties involved.
☐ Degree, HNC or equivalent in biological subject ☐ Interest in mathematics/statistics desirable ☐ Mechanical aptitude an advantage ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2251-£2842) or Scientific Officer (£1493-£2352) according to age and experience ☐ Ref: SB/1/AK ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

UNIVERSITY OF EDINBURGH

DEPARTMENT OF CHEMISTRY

RESEARCH ASSISTANT

Applications are requested for the post of Postdoctoral Research Assistant who will work under the joint direction of Professor E. A. V. Ebsworth and Dr T. A. Stephenson on isomerisation and exchange in some compounds of selenium. The work will involve synthetic and spectroscopic studies, and applicants should have had experience in the handling of compounds that are thermally unstable and sensitive to air and moisture.

The contract will run for 2 years at a starting salary of up to £2,058, starting on April 1, 1974.

Applications (in writing) should be addressed to: Professor E. A. V. Ebsworth, Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh EH9 3JJ.

The closing date for applications is March 1, 1974. Please quote reference 5000. (206)

UNIVERSITY
OF DUBLIN
Trinity College

JUNIOR LECTURER IN APPLIED MATHEMATICS

Applications are invited for the above post. Candidates should have a research interest in one of the following areas: Applied Mathematics, Theoretical Physics, Mathematical Biology or Numerical Analysis.

Salary scale: £1,969 by £126 to £2,473.

Marriage and children's allowances are paid and there is a non-contributory F.S.S.U.-type Pension Scheme.

Further particulars and application forms may be obtained from:

The Staff Secretary,
West Theatre,
Trinity College,
Dublin 2,

who will receive completed applications up to February 18, 1974.

(177)

UNIVERSITY OF OXFORD

DEMONSTRATORSHIP IN DEVELOPMENTAL BIOLOGY

The Lincare Professor of Zoology proposes to appoint, on or before September 1, 1974, a Departmental Demonstrator in Developmental Biology. The salary will be on a scale rising to £2,283 (with F.S.J.M.).

It is hoped that the Demonstrator will cooperate with Dr R. L. Gardner and Dr C. F. Graham in the teaching of Reproduction and Developmental Biology. Research facilities are available for the Demonstrator.

Applications (if possible, seven copies, except in the case of overseas applicants who need only submit one copy) should be sent to Professor J. W. S. Pringle, Department of Zoology, South Parks Road, Oxford OX1 3PS, not later than February 28. They should include a statement of age, qualifications and experience, and the names of two referees. (106)

DEPARTMENT OF BIOLOGY
QUEEN'S UNIVERSITY
KINGSTON, ONTARIO

Applications are invited for 3 positions in this department in the general areas (i) vertebrate biology, (ii) cell or developmental biology, and (iii) experimental plant science. Well qualified candidates in related fields may also be considered.

Appointments will be made at the rank of Assistant Professor to start July 1 or September 1, 1974, and will initially be for a period of 1 to 3 years. Successful candidates will be expected to teach comparative anatomy, or introductory cell biology, or plant science (as appropriate), and participate in the graduate and research programmes of the department.

Apply with curriculum vitae to Dr G. R. Wyatt, Head of the Department of Biology, Queen's University, Kingston K7L 3N6, Canada. (118)

Research Assistant

£2677-£2964

The Health Education Council is responsible for developing and promoting health education activities in England, Wales and Northern Ireland.

The Research Assistant will be responsible to the Chief Medical Officer for a wide range of work including monitoring relevant, specialist literature, for example conference reports and news items in the field of health education—linked research in medical, biological and social sciences — providing bibliographies, briefs and abstracts — preparing reports for the Research Committee — carrying out feasibility studies including the design of research protocols.

Candidates must have a good degree in the biological or social sciences; experience of information systems and a flair for creative, scientific writing would be definite advantages.

An additional attraction is that facilities may be provided for original work at Ph.D level including supervision by the Head of an appropriate University.

Please write for an application form, quoting reference U.42, to:

The Secretary,
Health Education Council,
78 New Oxford Street,
London WCIA IAH.

The
Health
Education
Council

Seeking a career in Publishing?

Creative Planner - Marketing

This is a unique post in scientific, technical and medical publishing. The creative planner will work closely with our house editors to report on progressive topics in biological, medical and social sciences, for which useful and marketable titles should be commissioned; this will entail extensive discussions with experts in Universities and Industries. The creative planner will equally be responsible for the promotion and advertising of a very broad range of new and backlist titles under the broad heading of Life Sciences. This work will entail the assessment of the market (world-wide); the preparation of suitable 'communication' material which will be readily acceptable and of interest to scientists; liaison with sales and editorial staff and the ability to continually assess performance and plan work in advance. This will be a particularly fruitful job to anyone who wishes to work across a broad spectrum.

The applicant must be prepared to travel and should preferably be able to drive. Write giving full details to:

Training & Personnel Manager,
Pergamon Press Ltd, Headington Hill Hall, Oxford OX3 0BW (235)

DUBLIN INSTITUTE FOR ADVANCED STUDIES

SCHOOL OF THEORETICAL PHYSICS

Applications are invited for a post as Assistant Professor in the School tenable for one or two academic years commencing October 1, 1974.

Salary: £3,091 per annum plus marriage and family allowances.

Applicants should send a curriculum vitae and list of publications, together with the names of two referees, so as to reach the undersigned not later than March 15, 1974.

The Registrar,
Dublin Institute for Advanced Studies,
10 Burlington Road,
Dublin 4, Ireland. (160)

CSIRO

AUSTRALIA

RESEARCH SCIENTIST

DIVISION OF MINERALOGY-FLOREAT PARK, W.A.

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 or whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: GEOLOGY

GENERAL: The Division of Mineralogy, a constituent of the Minerals Research Laboratories, conducts research on the mode of origin and characterization of deposits of economic minerals, and on the development of techniques in exploration. It has its headquarters in Floreat Park, W.A. and laboratories at North Ryde, N.S.W. and Canberra, A.C.T. The Appointee will be located at Floreat Park. As part of its geochemical investigations the Division is collaborating with the Division of Soils on the inter-relation of secondary geochemical dispersion, regional structural patterns, geomorphology and paleography, particularly in the arid areas of the Archaean Shield of Western Australia.

DUTIES: A senior research geologist is required to take part in this programme, initially aiming to elucidate the development of the present landscape through geological time, and the consequences of this development in determining geochemical dispersion.

QUALIFICATIONS: A Ph.D. in geology and demonstrable research ability. Appropriate research experience preferably with an established interest in the paleogeography of arid terrains. Experience of the Yilgarn Block of Western Australia would be a special advantage.

SALARY: Appointment will be made within the salary ranges of Senior Research Scientist or Principal Research Scientist $A12,298–$A17,077 p.a.

TENURE: This is a three year appointment.

Applications stating full personal and professional details, the names of at least two professional referees and quoting reference number 604/114 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
London,
WC2B 6BD
by the 15th February, 1974

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(227)

AGRICULTURAL RESEARCH COUNCIL

MEAT RESEARCH INSTITUTE

Applications are invited for a new post in the Abattoir Section which will be concerned initially with investigations into stress and disease transmission during transport and lairing of slaughter stock in relation to carcass quality.

MINIMUM QUALIFICATIONS: A first or upper second class honours degree in animal science or physiology, together with appropriate postgraduate research experience.

SALARY: Scientific Officer scale (£1,318-£2,177 p.a.). Higher Scientific Officer scale (2,076-£2,667 p.a.) depending on qualifications and experience; a minimum of 2 years postgraduate experience being required for appointment in the HSO grade. A higher grading may be offered to a particularly well qualified candidate.

This post is permanent and pensionable (FSSU with a 4½% allowance on salary to offset contributions).

Application forms quoting AB 18: Secretary, Meat Research Institute, Langford, Bristol, BS18 7DY. (201)

UNIVERSITY OF GUELPH

DEPARTMENT OF CHEMISTRY

FACULTY POSITION

Applications are invited for a faculty position at the rank of professor, to begin September 1, 1974, to January 1, 1975. Candidates must have a Ph.D. degree in chemistry or biochemistry, a considerable record of research accomplishment in biochemistry or biophysical chemistry, and teaching experience in chemistry or biochemistry. Salary will depend on qualifications and experience. Duties include teaching, supervision of graduate research, and independent research.

Applicants should provide a full curriculum vitae and the names of three referees to A. K. Colter, Chairman, Department of Chemistry, University of Guelph, Guelph, Ontario N1G 2W1, Canada. (115)

TECHNICIAN required to assist with original biochemical and immunological research on cancer. Experience in a relevant subject is desirable but not essential. The successful candidate will be appointed on a salary scale of £1,440 to £2,292.—Apply enclosing a curriculum vitae and the names of two referees to: Dr. G. Wiernik, Research Institute, Churchill Hospital, Headington, Oxford. (91)

THE CHINESE UNIVERSITY OF HONG KONG

Applications are invited for the following positions in the University. The Colleges to which posts are assigned are specified in brackets.

POST AND SPECIALISATION

FACULTY OF SCIENCE

SENIOR LECTURESHIP IN BIOCHEMISTRY (United College): The candidate should possess a Ph.D. degree or its equivalent with expertise in the field of Endocrinology. Preference would be given to candidates who are also experienced in Biochemical Embryology and related areas.

LECTURESHIP IN BIOCHEMISTRY (United College): The candidate should have a Ph.D. degree or its equivalent with training in Human Biochemistry and/or Nutrition. Prior teaching experience is essential. Demonstrable ability in research will a definite asset.

LECTURESHIP IN BIOLOGY (Chung Chi College): Applicants should hold a higher degree or have good experience in Marine Biology; experience of mariculture would be an advantage. The appointee will take part in the teaching of the marine sciences and may be required also to undertake teaching in the more general courses provided by the department. There are excellent facilities at the Marine Science Laboratory of the University for teaching and research.

GENERAL REQUIREMENTS

Candidates for Senior Lectureships should have a higher degree, preferably a Ph.D. in a relevant field, considerable university teaching and research experience and academic publications of originality and merit. Candidates for Lectureships should have a higher degree (preferably a Ph.D.) in a relevant field, with appropriate university teaching and/or research experience.

SALARY (IN £)

Senior Lecturer: £5,797 to £7,787 per annum (man or woman); Lecturer: £3,720 to £6,234 per annum (male), £3,574 to £6,234 per annum (female).

(Entry points depend on qualifications and experience. Equalisation of male and female salaries will be achieved by April 1975.)

OTHER CONDITIONS OF SERVICE

These include: (1) Superannuation (5 per cent employee, 15 per cent University); (2) Medical benefits; (3) Long leave (for all appointees except Language Instructors); (4) Housing accommodation or allowance in lieu thereof for all Senior Lecturers and appointees on Lecturer rank engaged on overseas terms. Housing allowance for appointees at Lecturer rank on local terms whose salary is above the Bar (married women excepted); (5) Passages for appointees on Assisted Lecturer rank and above recruited from abroad on appointment, and also on home leave if engaged on overseas terms.

ASSUMPTION OF DUTY

All appointees are expected to assume duty August 1, 1974, or as soon as possible thereafter.

APPLICATION PROCEDURE

Further details and application forms may be obtained from the Registrar/Academic Registrar of the College concerned. All three Colleges are situated at Shatin, N.T. Application forms, in triplicate, should be returned together with a covering letter and copies of credentials, marked "APPLICATION" on cover, as soon as possible. (199)

PAHLAVI UNIVERSITY

COLLEGE OF ARTS AND SCIENCES
SHIRAZ, IRAN

Applications are invited for positions in Astronomy and Physics beginning fall 1974, at the ASSISTANT/ASSOCIATE PROFESSOR level. Duties include teaching B.Sc. and M.Sc. students and some research. Field of solid state, nuclear, and astrophysics are represented in the department. A Varian X-band E.P.R. Spectrometer is in operation, and a 20-inch Cassegrain reflector with a photoelectric photometer is expected to be in operation by July 1974.

Ph.D. is required. Appointments will be made on a two-year renewable contract basis with an annual salary range equivalent to $12,000 to $16,000 depending on qualifications and experience. Return fare included.

Send résumé, curriculum vitae and confidential recommendations from three references to Dean Vessal, from whom particulars may be obtained. Deadline for applications is April 1, 1974. (107)

THE QUEEN'S UNIVERSITY OF BELFAST

CHAIR OF GEOLOGY

Applications are invited for the Chair of Geology which will be vacated on September 30, 1974, on the resignation of Professor Alwyn Williams, FRS. The salary is £6,462 with contributory pension rights under the FSSU.

Applications should be received by March 1, 1974. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland. (Please quote Ref. 74/N.) (207)

UNIVERSITY OF PRETORIA, PRETORIA, SOUTH AFRICA

INSTITUTE FOR GEOLOGICAL RESEARCH ON THE BUSHVELD COMPLEX

DIRECTOR

Applications are invited for the post of Director of the above-mentioned Institute which is to be established and attached to the Department of Geology. The Director will have full professorial status and as chief executive officer of the Institute will be assisted by a Board whose members represent organisations subventing the Institute. His duties will include the following:

(a) To execute the research policy of the Board of Control.

(b) To coordinate and guide research on the Bushveld Complex by research scholars and postgraduate students.

(c) To give a limited number of lectures to postgraduate students in the Department of Geology.

Candidates must have at least a Ph.D. or equivalent qualification.

Salary: R7,500 × 300–R9,900 plus an additional 15% of salary in the form of a pensionable allowance (£1 = R1,60 approximately). The commencing salary will depend upon qualifications and experience.

A vacation bonus is payable according to Public Service regulations. The University has a pension fund, a medical aid fund, a subsidy scheme for housing loans and a group insurance policy scheme with attractive benefits, for permanent full-time members of staff.

Application forms are obtainable from the Registrar (Academic), University of Pretoria, Pretoria 0002, South Africa.

Applications close on February 28th, 1974.

(214)

BLUE CIRCLE GROUP

inorganic chemist - kent

Current demand for cement and cement products enables this prominent company to provide opportunity which few others can match. This position carries an excellent negotiable salary and other benefits, which include profit sharing bonus, pension and advantageous house purchasing schemes, after appropriate qualifying service.

This is an ideal opportunity for a young graduate to gain invaluable experience. You will be involved in Research and Development work concerning special cements as well as cement based materials and associated products.

Although some post graduate experience in silicate chemistry or cement based materials would be advantageous, it is not essential.

Please include full professional details in your letter to:

The General Manager,
The Associated Portland Cement
Manufacturers Ltd,
Central Research Laboratories,
Greenhithe, Kent.

(222)

THE OPEN UNIVERSITY

ACADEMIC APPOINTMENTS IN EARTH SCIENCES AND CHEMISTRY

EARTH SCIENCES

Two appointments are available, either as two-year contract Lectureships or as one/two-year Secondments. Successful candidates will assist in the preparation of a third level course in Earth Science Techniques and Methods.

CHEMISTRY

Two appointments are available. One appointment will be made with tenure; the second appointment will be a two-year contract Lectureship or one/two-year Secondment. Candidates should have special interests in either Organic Chemistry or in Inorganic/Physical Chemistry.

The preparation of Open University courses involves writing course text and assessment materials, making television and radio programmes, devising home experiment kits, and planning and participating in Summer School activities. Applicants should have a keen interest in teaching and should be willing to experiment with the media available. The successful candidates will be expected to maintain an active interest in their research field.

Appointments are available from April 1, 1974, or as soon as possible thereafter. Lecturer salary scale: £1,929-£4,548 per annum with FSSU benefits.

Full details are available from The Acting Personnel Manager (SL3), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL. (Tel: Milton Keynes 74066, ext. 3068.) Closing date for applications: Thursday, February 7, 1974. (200)

CSIRO

AUSTRALIA

RESEARCH SCIENTIST

AGRO-INDUSTRIAL RESEARCH UNIT—
CANBERRA, A.C.T.

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: **SIMULATION OF AGRO-INDUSTRIAL SYSTEMS**

GENERAL: The newly created Agro-industrial Research Unit (of three scientists) will examine the possibility of exploiting the year-round growth of crops in the tropics by year-round harvesting and industrial processing of a range of crops, and by feeding of cattle on industrial by-products. Related studies in crop processing and animal feeding are being undertaken at the CSIRO Divisions of Applied Chemistry in Melbourne and Animal Physiology in Sydney respectively.

The appointee will be based in Canberra, but will travel extensively to collaborating laboratories in Sydney and Melbourne and to Northern Australia.

DUTIES: To undertake collaborative research into simulation of the biological, physical and economic processes of complex agro-industrial systems.

QUALIFICATIONS: A Ph.D. degree or equivalent qualifications in science, agricultural science or engineering, and demonstrable research ability. Some experience in simulation and economics is essential.

SALARY: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: $A9,380–$A14,290 p.a.

TENURE: Either an indefinite or a fixed term appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 267/5, should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
London,
WC2B 6BD
by the 15th February, 1974

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(225)

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
DEPARTMENT OF NEUROLOGY

RESEARCH WORKER required immediately for biochemical/physiological studies in experimental epilepsy. Neurochemical experience an advantage. Applicants wishing to visit the Laboratory may phone 01-703 5411, ext. 370, for an appointment. Initial salary up to £1,929 plus £162 London allowance, renewable annually up to 3 years.

Apply to the Secretary, Institute of Psychiatry, De Crespigny Park, London SE5 8AF, quoting reference BSM/N. Applications should be received by January 29, 1974. (183)

UNIVERSITY OF KEELE
LECTURER IN MATHEMATICS

Applications invited for post of Lecturer in Mathematics. Initial salary on points 1 to 3 of scale £1,929-£4,548 per annum. Further particulars and application forms from The Registrar, The University, Keele, Staffs., ST5 5BG, to whom they should be returned by February 1, 1974. (219)

SWISS INSTITUTE OF TECHNOLOGY
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a junior and senior research position in the field of membrane biochemistry. Candidates for the junior position should have recently obtained their Ph.D. For the senior position candidates should have at least two years post-doctoral research experience.

Applications should be sent to: Professor G. Semenza, Swiss Institute of Technology (ETH), Universitätsstr. 16, CH-8006 Zürich, Switzerland. (216)

UNIVERSITY OF CAMBRIDGE
RESEARCH ASSISTANT

Applications are invited for the position of Graduate Research Assistant from February 1 to July 30, 1974. The work will involve the application of operant techniques to the study of nest-building behaviour in canaries.

Applications including a brief curriculum vitae and the names of two referees should be sent to Dr Joan Stevenson-Hinde, Sub-Department of Animal Behaviour, Madingley, Cambridge CB3 8AA. (110)

UNIVERSITY OF NEW SOUTH WALES
SCHOOL OF ANATOMY
LECTURER

Distinguished academic record required. Medical qualifications advantageous. Facilities exist for wide range of research including electron microscopy, qualitative and quantitative cytology and tissue culture.

Salary $A8,698 range $A11,982 per annum. Commencing salary according to qualifications and experience.

For details of appointment, including superannuation, study leave and housing scheme, write to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **March 1, 1974.** (230)

THE UNIVERSITY OF MANCHESTER
LECTURER IN PSYCHOLOGY

Applications are invited from candidates with special competence in the sphere of child study. The successful candidate, who will succeed Dr R. R. Skemp on his appointment to a Chair at the University of Warwick, will direct the Child Study units in the Department. Salary range per annum: £1,929 to £4,548. F.S.S.U.

Further particulars and application forms (returnable by February 1) from the Registrar, The University, Manchester M13 9PL. Quote ref.: 1/74/Na (233)

THE UNIVERSITY OF MANCHESTER
LECTURER IN ZOOLOGY

Applications invited for the above post. An interest in ecology, entomology or chordate biology would be an advantage. Salary scale per annum: £1,929 to £4,548, but initial salary will not exceed £2,388 per annum. F.S.S.U.

Particulars and application forms (returnable by February 23) from the Registrar, The University, Manchester M13 9PL. Quote ref.: 5/74/Na. (234)

UNIVERSITY OF ALBERTA

Applications for GRADUATE STUDIES IN PHARMACOLOGY for the degrees of M.Sc. and Ph.D. are invited from students with a background in Biochemistry, Pharmacy, Biology, Chemistry or Medicine. Opportunities exist in Biochemical Pharmacology, Neuropharmacology and Smooth Muscle Pharmacology. Successful applicants may be eligible for financial assistance.

For further information write to: Dr J. S. Charnock, Chairman, Department of Pharmacology, University of Alberta, Edmonton, Alberta, Canada, T6[illegible] 2H7. (X3)

UNIVERSITY OF ALBERTA

Applications are invited for a post-doctoral position in Biochemistry available in the summer of 1974 for two years. The areas of research include DNA replication, circular DNAs and multistranded polynucleotides. Candidates should have a strong chemical and physical background. A Ph.D in chemistry would be a suitable candidate. The starting salary would be $8,900 p.a.

A curriculum vitae and letters of recommendation are required from applicants who should write to Dr A. R. Morgan, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada T6G 2E1. (211)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)
HAMPSTEAD, NW3 7ST

GRADUATE EXPERIMENTAL OFFICERS required in the Chemistry Department for work in connection with the Circular Dichroism Unit, and the Medical Research Council Steroid Reference Collection. Salary scale £1,679 to £1,939 per annum according to age and experience.

Please write or telephone to the Personnel Officer (N), Westfield College, Hampstead NW3 7ST. 01-435 7141. (197)

GRADUATE RESEARCH ASSISTANT REquired for research project in human pathology. Degree in biology and experience in electron microscopy technology preferred. Salary in region of £1,600.—Applications to Professor W. B. Robertson, Histopathology Department, St. George's Hospital, Blackshaw Road, Tooting, London SW17 0QT. (185)

APPLICATIONS ARE INVITED FOR AN appointment involving undergraduate instruction in **mineralogy** and **petrography** and interaction with the graduate programme. The Department's research activity emphasizes environmental geology and preference will be given to applicants concerned with the mineralogy and geochemistry of sedimentary environments. Rank open; salary commensurate with experience. A temporary one-year appointment is also available in **economic geology.**—Send résumé to: Dr R. N. Farvolden, Chairman, Department of Earth Sciences, University of Waterloo, Waterloo, Ontario, N2L 3G1. (210)

THE QUEEN'S UNIVERSITY
OF BELFAST

LECTURESHIP IN PHYSICS

(Optical and Magneto-Optical Properties of Thin Films)

Applications are invited for the post of Lecturer in Physics, tenable from October 1, 1974, or such other date as may be arranged. The successful applicant will be required to undertake teaching at undergraduate and postgraduate level and to take part in research within a group (under the general direction of Professor P. H. Lissberger) concerned with studies of the optical and magneto-optical properties of thin solid films in relation to their structure. Preference will be given to applicants with experimental and theoretical interests in this field. Previous experience of the measurement and interpretation of the optical constants of solids is desirable. The appointment will be subject to a period of probation of up to three years in duration. Initial placing which will depend on experience and qualifications will be made at one of the first three points on the scale for lecturers: £1,929, £2,058, £2,223, rising to £4,548 with contributory pension rights under the FSSU.

Applications should be received by February 28, 1974. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. (Please quote Ref. No. 74/N.) (208)

PLYMOUTH GENERAL HOSPITAL

A SCIENCE GRADUATE is required to fill a new post based at Plymouth General Hospital, for work principally involving saturation analysis and related techniques. Initially it is intended to set up tests of pituitary, thyroid and adrenal function, plus a number of other assays, and there will be some work involving liquid scintillation counting. In addition to the laboratory techniques, the successful candidate will take day-to-day charge of automatic counting equipment.

Previous experience in this field of work is sential and further details may be obtained by ntacting Dr. Janice Went, telephone Plymouth --003.

Application forms may be obtained from the Hospital Secretary, Plymouth General Hospital, North Friary House, Plymouth PL4 8QQ, and should be returned by not later than 14 days from the appearance of this advertisement. (191)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MEDICAL PHYSICS

M.Sc. IN MEDICAL PHYSICS

The Department provides a 12 months' course in Medical Physics, commencing October 1 each year. Candidates should have a first or second-class honours degree in Physics or Electronics or Engineering, or equivalent qualifications.

The course covers a wide range of the applications of physics to medicine and is designed to prepare candidates for a career in Medical Physics.

The Science Research Council and Medical Research Council have accepted the course as suitable for the tenure of their Advanced Course Studentships. The course has been endorsed by the Departments of Health in London and Edinburgh.

Further details available from the Secretary, Department of Medical Physics, University of Aberdeen. (X77)

MASSEY UNIVERSITY
PALMERSTON NORTH, NEW ZEALAND

LECTURER IN GENETICS

Applications are invited for the above-mentioned position in the Department of Microbiology and Genetics; the department is responsible for courses leading to B.Sc., B.Sc.(Hons.), M.Sc. and Ph.D. degrees. The successful applicant will assist in the further development of Genetics as an area of teaching and research and will participate in the offering of an introductory course in cell biology to first year students.

Salary: NZ$6,575 to $NZ8,343.

Further details of this position and of the University, together with general conditions of appointment, may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **February 15, 1974.** (195)

Ministry of Agriculture, Fisheries and Food
Plant Pathology Laboratory, Harpenden, Herts.

Agricultural Entomologist

■ **To join team providing technical advice on maintenance of high health standards in consignments of imported/exported plants and plant produce ■ Liaison with Plant Health and Seeds Inspectorate and assistance with technical training in entomology.**
☐ Degree or equivalent in Applied Biology, Agriculture or Horticulture ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2076-£2667) or Scientific Officer (£1318-£2177) according to age and experience ☐ Ref: SB/1/AG ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Department of Health and Social Security, London

Information Scientist

■ **In Medical Division ■ To compile information on chemical contamination of food, and environmental pollution ■ Help develop data storage and retrieval system.**
☐ Degree, HNC or equivalent in chemical or biological subject ☐ Age under 27 ☐ Appointment as Scientific Officer (£1493-£2352) ☐ Ref: SB/1/K ☐ Closing date 1 February 1974.
☐ Application forms from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

CIVIL SERVICE

UNIVERSITY OF CALGARY, GRADUATE Teaching and Research Assistantships are available for students proceeding to the Ph.D. or M.Sc. degrees in all branches of Chemistry and Biochemistry. The Assistantships are valued from $4,100 to $5,000 per annum and carry remission of programme fees and travel allowance.

For further information write to: Department of Chemistry, Calgary, Alberta T2N 1N4, Canada. Please indicate field of interest. (X35)

RESEARCH TECHNICIAN required for work on the development of assays for vitamin-D and related compounds. Experience of radioimmunoassays and competitive protein binding assays useful but not essential. Salary on the Technician Whitley Council scale according to experience.—Applications, together with qualifications and names of two referees to Dr J. L. H. O'Riordan, Medical Unit (N), The Middlesex Hospital Medical School, London, W.1. Telephone 636 8333 Ext. 595. (232)

Senior Pharmacologist for Research

Applications are invited for a senior post in our Pharmacology Department in Welwyn Garden City. The Department is responsible for carrying out research and screening work aimed at the development of new drugs and the pharmacologists participate in the research programmes of interdisciplinary groups working in specific areas.

The senior pharmacologist we appoint will direct the research programme of a team of pharmacologists engaged in cardiovascular research. Applicants should be in their thirties and hold a Ph.D., together with at least five years postdoctoral experience. Previous experience in cardiovascular research is desirable but not essential and of less importance than proven ability to direct original and creative research.

Our Pharmacology Department has recently moved into new laboratories where the facilities and working conditions are excellent. Conditions of Service will be attractive and in appropriate cases assistance with relocation will be offered.

Roche Products Limited is part of a major international pharmaceutical concern based in Switzerland and is itself one of the leaders in the industry in the United Kingdom. Applications in writing should be addressed to the Senior Welwyn Personnel Officer.

ROCHE

Roche Products Limited
Welwyn Garden City Hertfordshire AL7 3AY

Head of Animal Supplies

The Research Department, situated in Nottingham, has a vacancy for a person to take full charge of the Animal Supplies and Services Unit, with the responsibility for the breeding, purchase, handling and health of a wide variety of laboratory animals for use in medical research. The Unit, comprising small animal, dog and primate sections, is being enlarged. Extensive new animal facilities are planned and the man appointed will be expected to participate in the development of this project. Staff numbers over 25.

The person appointed is likely to be qualified in veterinary science and may possess experience of laboratory animal husbandry.

Employment conditions are attractive and include profit sharing and contributory pension schemes. Assistance with re-location expenses will be given in appropriate cases.

Please write for further details and application form to: J. F. Pattison, Employment Manager,

Boots

The Boots Company Ltd.,
Station Street, Nottingham NG2 3AA.

(159)

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

TEMPORARY LECTURESHIP IN GENETICS

A temporary lectureship in Genetics for one year, with possible extension for a second year, is immediately available.

Teaching responsibilities will be primarily for a second-year class, and will cover aspects of Metazoan Genetics.

The research interests of the associated group is in the developmental genetics of *Drosophila*, including Embyrology and cell culture and good facilities are available. Candidates with other research interests will also be considered.

Appointment will be made on the Lecturer scale: £1,929 to £4,548 per annum, as soon as possible.

Application forms may be obtained from the Secretary of Science, Science Office (E), University of Sussex, Falmer, Brighton BN1 9RH.

(224)

BAKER MEDICAL RESEARCH INSTITUTE

MELBOURNE, AUSTRALIA

(RE-ADVERTISEMENT)

The Trustees of the Thomas Baker, Alice Baker and Eleanor Shaw Medical Research Institute invite applications for the position of:

DIRECTOR OF THE INSTITUTE

The present Director will be retiring from appointment in December 1974.

THE INSTITUTE

The Baker Institute is an autonomous organisation situated in the grounds of Alfred Hospital and adjacent to the Clinical Sciences Building of Monash University Medical School. The Institute is affiliated with Monash University which means that the research facilities of the Institute are available for promoting the teaching of both undergraduate and postgraduate students of the University, up to Ph.D. level. For both bodies it makes possible the integration of trained personnel and the research facilities of both the University and the Institute, for the benefit of medical education and research. The main financial support of the Institute is presently derived from the Thomas Baker (Kodak), Alice Baker and Eleanor Shaw Benefactions.

The Institute building has recently been rebuilt, all laboratories are air-conditioned and equipped for work in biochemistry, physiology, pharmacology and histology. The laboratories of Alfred Hospital Clinical Research Unit are presently housed in the Institute building. The building is linked with the new Alfred Hospital Ward Block now under construction. Arrangements with the Hospital will permit the successful applicant access to clinical facilities, including beds, if such are appropriate to the research programme.

REQUIREMENTS

Applicants must be medical or biological scientists with research experience, demonstrated ability in team leadership and some appropriate administrative experience.

CONDITIONS

* The appointment is for at least five years and will be reviewed not later than four years after the appointment, when it may be extended as appropriate.
* A generous salary is contemplated, and will be based on qualifications and experience.
* Superannuation is available under Institute Scheme.
* Commencing date January 1975 or later by negotiation.
* Assistance will be given in meeting the cost of removal expenses to a successful applicant not resident in Melbourne and in some circumstances with the cost of repatriation.

Further details may be obtained from the Director, Dr. T. E. Lowe.

Applications close with the undersigned on April 30, 1974.

G. B. CANHAM,
Secretary.

Baker Medical Research Institute,
Commercial Road,
Prahran, Victoria 3181,
Australia.

(193)

TECHNICIAN (Grade 3) required to assist in the running of a small research laboratory (4 workers) and to help with experiments on isolated tissues. Some knowledge of biology and chemistry essential. Salary in the range £1,650 to £1,920 plus £175 London Weighting.—Application form from Personnel Officer (Technical Staff FE2), University College London, Gower Street, London WC1E 6BT. (231)

MOLECULAR BIOLOGY AND BIOCHEMISTRY

UNIVERSITY OF CALIFORNIA, IRVINE

Applications and nominations are invited for permanent faculty positions available in September 1974. (1) A senior position in molecular genetics, (2) A junior position in an area of molecular biology, biochemistry or biophysics. Selection will be made on the basis of evidence of excellence in research and teaching. More consideration will be given to the candidate's qualifications than to the area of research. Send curriculum vitae, bibliography and list of three references to Dr Robert C. Warner, Chairman, Department of Molecular Biology and Biochemistry, University of California, Irvine, Irvine, California, 92664.

The University of California is an equal opportunity employer and encourages applications from women and minority group candidates. (204)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

BOTANIST/PLANT PATHOLOGIST to assist with work on infection of cereals by powdery mildew and testing for fungicide tolerance. Temporary post for two years. Minimum qualification: pass degree, HNC or equivalent.

Appointment in grade of Scientific Officer. Starting salary £1,318-£1,590 (depending on qualifications and experience) on scale to £2,177.

Applications, giving names of two referees and quoting Ref. 212, to the Secretary by February 8, 1974. (209)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

LECTURESHIP IN ANIMAL BEHAVIOUR

Applications are invited for the post of Lecturer in Animal Behaviour from October 1, 1974.

Salary scale: £1,929-£4,548, with FSSU.

Six copies of applications (one from overseas candidates), naming three referees, should be sent by February 15, 1974, to the Registrar, University of York, Heslington, York YO1 5DD, from whom further details may be obtained. Please quote reference number 11/3092. (217)

UNIVERSITÄT ZU KÖLN GERMANY

INSTITUT FÜR GENETIK

E. COLI GENETICIST

A post-doctoral research position for work in association with Professor B. Müller-Hill will be available immediately. The appointment will be for two to three years. The salary will be on the scale of ca. 27,000,— DM per annum.

Applications, with curriculum vitae and the names of two referees, should be sent to Professor B. Müller-Hill, Institut für Genetik der Universität zu Köln, Köln 41, Weyertal 121, West Germany. (25)

THE UNIVERSITY OF ADELAIDE

Applications are invited for the following appointment:

TEACHING FELLOW IN ELECTRICAL ENGINEERING with interests in communication systems, signal processing, speech analysis, system assessment, power systems control, microwave engineering. Interaction with industry is encouraged. (1.2.74).

Salary scale: Teaching Fellow $A7,270 by $A286 (3) by $A285 (2) to $A8,698; a non-superannuated and non-tenured appointment.

Further particulars about this post and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, the University of Adelaide, North Terrace, Adelaide, South Australia, 5001. (223)

CELLULAR AND MOLECULAR BIOLOGY

A senior position at the rank of Full or Associate Professor is available in the Department of Biology, York University, Toronto, tenable July 1, 1974. Preferred areas of research interest are: genetics and biochemistry of development, cellular and molecular genetics, neurobiology. Exceptional junior candidates may also be considered. Salary negotiable and commensurate with rank.

Send curriculum vitae, reprints and names of three referees to Professor J. D. Friesen, Department of Biology, York University, 4700 Keele Street, Downsview, Ontario M3J 1P3, Canada. (114)

CSIRO

AUSTRALIA

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

RESEARCH SCIENTIST

DIVISION OF TEXTILE INDUSTRY

Geelong, Vic.

FIELD: **POLYMER CHEMISTRY**

GENERAL: The Organization's Division of Textile Industry located at Geelong, Victoria, is carrying out research concerned broadly with physical and chemical investigations related to wool textile processing. Facilities include well equipped laboratories for basic chemical and physical studies and full scale mill equipment for application of results.

DUTIES: To carry out basic studies on the application of polymers to wool and to work on the development of polymers for shrink-proofing and permanent press processes.

QUALIFICATIONS: A Ph.D. degree or equivalent qualifications together with demonstrable research ability. Experience in preparative organic chemistry, particularly polymer synthesis is desirable.

SALARY: Appointment will be made within the salary ranges of Research Scientist, or Senior Research Scientist, $A9,380–$A14,290 p.a.

TENURE: This is a three year appointment.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 464/558 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
London,
WC2B 6BD

by the 15th February, 1974

Applications in the U.S.A. and Canada should be sent to:
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(228)

THE HUNTSMAN MARINE LABORATORY

SALMON RESEARCH CENTER

requires

FISHERIES BIOLOGIST IN CHARGE OF SALMONID CULTURE AND TRAINING

General—The newly formed Center is initiating a programme of research in Atlantic Salmon Restoration, with particular emphasis on genetics and selective breeding. There is an immediate opening for a key individual who will assume responsibility for the culture and culture training programme.

Duties—The successful applicant will assist in the design and construction of North America's first full scale salmon research-culture facility, will be responsible for implementing complex research programmes and advanced culture techniques, and will manage the Center's proposed advanced training programme for fish culturists.

Qualifications—Candidates should have a professional fisheries background and extensive experience in salmonid fish culture, in particular with Atlantic Salmon.

Salary—Negotiable.

Send résumé to: Dr John R. Calaprice, Director, North American Salmon Research Center, Huntsman Marine Laboratory, St Andrews, N.B., Canada. (205)

LA TROBE UNIVERSITY

MELBOURNE, AUSTRALIA

CHAIR OF MICROBIOLOGY

Applications are invited for the Chair of Microbiology. This is a Foundation Chair, and the Professor will initially be Chairman of the Department of Microbiology which the University intends to establish within the School of Biological Sciences in 1974.

Microbiology will be offered at undergraduate levels in the School of Biological Sciences in courses for the B.Sc. degree. It is planned that teaching will commence in March 1975. The appointee will be expected to participate in undergraduate and graduate teaching in general microbiology and to carry out research in his chosen field and be responsible for the administration and planning in the department. It is envisaged that teaching should begin at the second-year level. At present the school has departments of biochemistry, botany, genetics and human variation, and zoology.

The date of commencement of the appointment will be by arrangement. Applications close March 15, 1974.

The salary will be $A19,102 and membership of the University's superannuation scheme is required.

Further information and application forms are available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia 3083. (184)

GLASGOW
COLLEGE OF
TECHNOLOGY

Department of Ophthalmic Optics

Senior Lecturer and Lecturer in Ophthalmic Optics

Applicants should hold degrees or professional qualifications in Ophthalmic Optics. In the case of the Senior Lectureship, a Higher Degree or Higher Diploma together with appropriate experience will be required.

A special interest in clinical aspects, visual optics, ocular pathology or ocular anatomy will be an advantage. Those appointed will be expected to contribute to the development of, and teaching in, areas of ophthalmic study up to Honours degree and post-graduate level.

Members of staff are encouraged to pursue research interests and to read for Higher Degrees.

Salary Scales: Senior Lecturer—Up to £4,023 per annum, depending upon experience, plus £117 per annum for approved teaching training. Lecturer—Up to £3,201 per annum, depending upon experience, plus £117 per annum for approved teaching training.

Application forms and further particulars may be obtained from The Director, Glasgow College of Technology, North Hanover Place, Glasgow G4 0BA, and should be returned as soon as possible. (149)

MEETING

NATO—ADVANCED STUDY INSTITUTE

Exploitation of Seismological Network

A meeting organised jointly by the Royal Norwegian Council for Scientific and Industrial Research and Cranfield Institute of Technology, England, and sponsored by the NATO Science Committee, will be held from April 22nd to May 3rd, 1974, in Oslo, Norway.

The meeting will be concerned with the computational and mathematical procedures required for seismic array processing and the function of communication network used for this purpose.

It is intended to bring together those working in the fields of computation, communication, seismology and related areas—particularly those concerned with the use and implementation of seismic systems for earthquake and explosion identification.

Lecturers include: Dr. J. Bendat (U.S.A.); Prof. O. Dahlman (Sweden); Dr. E. Husebye (Norway); Dr. B. Kennett (U.K.); Prof. P. Kirstein (U.K.); Dr. R. Lacoff (U.S.A.); Prof. S. Mueller (Switzerland); Dr. D. Simpson (U.S.A.); Dr. H. Thiraway (U.K.); Dr. D. Weichert (Canada); Dr. P. Willmore (U.K.)

For further information and application for Fellowship to attend, please write to: Miss M. E. Williamson (Scientific Secretary), Computing Centre, Cranfield Institute of Technology, Cranfield, Bedford MK43 0AL, England.

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTS AL5 2JQ

PLANT PROTOPLAST AND TISSUE CULTURE STUDIES

A RESEARCH SCIENTIST is required to join a team in the Biochemistry Department working on the biosynthesis of amino acids in plant systems. The work will involve the selection of mutant plant lines having altered regulatory feedback characteristics. It is essential that the person appointed should have previous experience in higher plant protoplast and/or tissue culture studies. Minimum qualifications: first or upper second class honours degree.

Appointment in grade of Scientific Officer (£1,590 to £2,177) or Higher Scientific Officer (£2,076 to £2,667) depending on qualifications and experience. At least two years' appropriate experience is required for appointment in the higher grade. F.S.S.U. with a non-pensionable salary supplement of 4½ per cent to offset contributions.

Applications, naming two referees and quoting reference 217 to the Secretary by February 15, 1974. (244)

SCARBOROUGH, BRIDLINGTON, MALTON & WHITBY GROUP HOSPITALS

Applications are invited for the post of BIOCHEMIST (Probationary or Basic Grade) in the Group Pathology Laboratory, Scarborough Hospital, Yorkshire. Applicants should be about to graduate in Biochemistry, Chemistry, or one of the Biological Sciences, or hold the Associateship or Graduate Membership of the Royal Institute of Chemistry, or have relevant hospital experience. Excellent opportunities exist for in-service study leading to a higher qualification in particular the Mastership in Clinical Biochemistry. Whitley Council conditions of service apply.

Candidates are invited to visit this new laboratory by appointment with the Principal Biochemist. Tel. No. Scarborough 2121, Ext. 266.

Applications, together with the names of two referees, should be sent to:

The Consultant Pathologist,
Scarborough Hospital,
Scalby Road,
Scarborough, Yorks. (237)

BIOCHEMIST

required to work in department of Chemical Pathology on active endocrinological programme. Experience in radioimmunoassay an advantage but not essential. Opportunity to work for higher degree and for tr ing and experience in general clinical biochemis Salary according to Whitley scales.

Apply in writing to Prof J. R. Hobbs, Dept. of Chemical Pathology, Westminster Medical School, 17 Page Street, London, S.W.1. (238)

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTS AL5 2JQ

BOTANIST or BIOCHEMIST to investigate the function of growth substances in the development of sugar beet. Minimum qualifications 1st or upper 2nd class honours degree and some appropriate research experience (at least two years for appointment as HSO).

Appointment for two years in the first instance, in grade of Scientific Officer (£1,590 to £2,177) or Higher Scientific Officer (£2,076 to £2,667). F.S.S.U. Reference 210.

CHEMIST to assist with research on the effects of aerial pollution on crop plants. Minimum qualifications pass degree, HNC or equivalent.

Appointment for one year in the first instance in grade of Scientific Officer. Starting salary £1,318 to £1,590 (depending on qualifications and experience) on scale to £2,177. Reference 211.

Applications, giving full personal details and names of two referees to the Secretary by February 8, 1974. Please quote reference. (242)

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTS AL5 2JQ

BIOCHEMIST to join a team working on the enzymology and control of the biosynthesis of nutritionally essential amino acids in higher plants. Applicants should have a first or upper second class honours degree in biochemistry or a closely related subject.

Appointment in grade of Scientific Officer (£1,590 to £2,177) or Higher Scientific Officer (£2,076 to £2,667). At least two years' appropriate research experience is required for appointment in the HSO grade, but applications in the lower grade will be considered from people graduating in 1974. F.S.S.U. with a non-pensionable salary supplement of 4½ per cent to offset contributions.

Applications, naming two referees and quoting reference 216 to the Secretary by February 8, 1974. (243)

SUB-EDITORS

BUTTERWORTHS have vacancies for editorial staff in their Medical and Scientific departments. Previous experience of sub-editing manuscripts and all aspects of book publishing is essential. A wide scientific knowledge is necessary for applicants who wish to work on scientific books. The offices are situated in pleasant country surroundings at Borough Green, near Sevenoaks, Kent. The minimum salary for a qualified sub-editor is £2,405 per annum.

Please write, giving details of age, experience and qualifications, to Denise Lulham, Butterworth & Co. (Publishers) Ltd., 88 Kingsway, London WC2B 6AB. (241)

UNIVERSITY OF TORONTO

DEPARTMENT OF ZOOLOGY

ASSISTANT PROFESSOR (FOUR) OF ZOOLOGY

Applications are invited for four positions as Assistant Professor in the Department of Zoology, tenable from July 1, 1974.

The vacancies are in the fields of: 1. Genetics; Animal Behaviour; 3. Aquatic Invertebrates; 4. Vertebrate Physiology.

The successful applicants will be required to teach at both the graduate and undergraduate levels and to develop a research programme in their area of specialty.

The positions are established, with a minimum salary of $12,300 per annum, negotiable.

Applicants, who should have completed their Ph.D. and have Postdoctoral or similar experience, should send a curriculum vitae to Professor D. A. Chant, Chairman, Department of Zoology, University of Toronto, Canada M5S 1A1, to reach him not later than March 31, 1974. (236)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

RESEARCH FELLOW/SPECIAL RESEARCH ASSISTANT

Applications are invited for the above vacancy to work in a research group investigating problems connected with condensation of vapours of immiscible liquids.

This forms part of a research programme sponsored by the Science Research Council to investigate the mechanism of condensation, to develop design procedures and improvements to equipment. A pilot plant test rig will be available. In the latter part the work investigations on production scale plant may be undertaken.

Applicants should have suitable qualifications in Chemical Engineering or Mechanical Engineering.

Salary within the range £2,058 to £2,373 per annum plus F.S.S.U. contributions.

Enquiries and letters of application should be addressed to:

Dr G. A. Davies,
Department of Chemical Engineering,
U.M.I.S.T.,
Sackville Street,
Manchester M60 1QD. (239)

RESEARCH ASSISTANT REQUIRED BY INSTITUTE OF CANCER RESEARCH, Belmont, Sutton, Surrey, to join team studying immunotherapy of human malignant disease. The candidate will be required to measure by *in vitro* techniques the immunological response of patients to malignant cells. Experience in tissue culture essential and experience in immunological techniques desirable. Salary according to experience, in scale £1,770 to £2,418.—Please apply in duplicate to the Secretary, Institute of Cancer Research, 34 Sumner Place, London S.W.7, giving the names and addresses of two referees, and quoting ref. no. 301/B/496. (190)

FELLOWSHIPS AND STUDENTSHIPS

THE ROYAL SOCIETY

SCIENTIFIC INFORMATION RESEARCH FELLOWSHIP

Applications are invited for a SCIENTIFIC INFORMATION RESEARCH FELLOWSHIP for research likely to improve scientific information services. The appointment is tenable for two years in the first instance from October 1, 1974, and may be renewable annually up to a maximum of five years. The stipend will be in the range £3,597 to £4,257 per annum, with superannuation benefits.

Forms of application are available from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG and applications are receivable by February 28, 1974. (212)

CSIRO

AUSTRALIA

POSTDOCTORAL FELLOWSHIPS (THREE)

DIVISION OF HORTICULTURAL RESEARCH

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELDS: **PLANT PHYSIOLOGY AND BIOCHEMISTRY**

GENERAL: The Division is concerned primarily with research on perennial horticultural plants of the temperate and sub-tropical zones, especially grapevines and fruit trees. The current program includes studies in: plant breeding, plant protection, canopy manipulation, drying of grapes, the storage of pome fruits, photosynthesis and fruit development.

The Division has laboratories at Adelaide, South Australia; Merbein, Victoria; and Hobart, Tasmania. The successful appointees will be required to take up duties in Adelaide, South Australia.

DUTIES: To collaborate in research projects concerned with the formation and early stages of development of fruits and nuts. Fields of interest include pollination, parthenocarpy, embryo formation, ovary wall enlargement in fruits and kernel development in nuts. Approaches to include light and electron microscopy, measurements of nucleic acids and proteins, assays of the activity changes in enzymes concerned with carbohydrate and lipid metabolism.

QUALIFICATIONS: Ph.D. degree in biology, botany, biochemistry or plant physiology or equivalent qualifications with specialized training in enzymology or cytology, together with demonstrable research ability.

SALARY: The appointments will be made within the salary ranges of Research Scientist or Senior Research Scientist, $A9,380–$A14,290 p.a.

TENURE: These Fellowships will be available for a period of two years.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 490/239 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
London,
WC2B 6BD
by the 15th February, 1974

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(226)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF ELECTRICAL ENGINEERING

RESEARCH FELLOWSHIP

Applications are invited for a research fellowship financed by Arthur Holden & Sons Ltd., to work on the fundamental processes of surface coatings and electrostatic charging of powders. The successful applicant will join an established research group working on electrostatic deposition of materials with particular reference to industrial applications.

The fellowship is open to electrical engineers, physicists and chemists. A post-doctoral worker would be preferred but consideration would also be given to honours graduates having appropriate research experience. The post might be of interest to graduates with experience in surface physics.

The period of the appointment is two years and the salary will be up to £2,233 per annum.

Applications, giving details of age, qualifications and experience and the names and addresses of two referees, should be sent to the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH not later than February 28, 1974. Please quote reference No. Na 136/R. (220)

UNIVERSITY OF READING

UNIVERSITY RESEARCH FELLOWSHIPS

Applications are invited for one University Research Fellowship for independent research, normally of the value of £2,052 per annum.

Further particulars may be obtained from the Senior Assistant Registrar, Room 221, Whiteknights House, University of Reading, Whiteknights, Reading RG6 2AH, to whom applications (4 copies) should be sent by **February 11, 1974.** (179)

UNIVERSITY OF BRISTOL

LONG ASHTON RESEARCH STATION

AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

A studentship will be offered in 1974 for research in one of several fields relating to the work of the Station. For further details apply to the Secretary, University of Bristol, Research Station, Long Ashton, Bristol BS18 9AF. (202)

THE CITY UNIVERSITY

Department of Chemistry

Applications are invited for a

RESEARCH STUDENTSHIP

which is available for studies of the spontaneous ignition of hydrocarbon-air mixtures with special reference to the application of computer techniques. The value of the award will be at least equivalent to that of an S.R.C. Research Studentship and the successful candidate will be able to register for a Ph.D. degree.

Further details may be obtained from Professor C. F. Cullis, Department of Chemistry, The City University, St. John Street, London EC1V 4PB, to whom applications, together with the names of two referees, should be sent as soon as possible and in any case not later than February 5, 1974. (188)

UNIVERSITY OF HULL

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship (SRC) to work in collaboration with Dr R. Aveyard on the effects of electrolytes on aqueous solutions of surface active non-electrolytes. Research experience in thermodynamics, physical chemistry of electrolyte solutions, or colloid and surface chemistry would be an advantage.

The appointment, which is for two years, is immediately available at a salary of £2,037-£2,151 per annum.

Applications, giving details of qualifications, research experience, and the names of two referees, should be sent before January 31 to the Registrar of the University, from whom further particulars may be obtained. (218)

UNIVERSITY OF READING

UNIVERSITY POSTGRADUATE STUDENTSHIPS

Applications are invited for Postgraduate Studentships from persons who hold a first degree or who will have completed a first degree course by July 1974. The Studentships are tenable for a maximum period of three years from October 1, 1974, subject to annual renewal, and will be of the value of £695 per annum, together with payment of the Composition Fee and the fee for Associate Membership of the Students' Union.

Further particulars and application forms may be obtained from the Senior Assistant Registrar, Room 222, Whiteknights House, University of Reading, Whiteknights, Reading RG6 2AH, by whom applications (4 copies) must be received not later than **March 1, 1974.** (180)

UNIVERSITY OF OXFORD

GUINNESS RESEARCH FELLOWSHIPS IN MICROBIOLOGY

Candidates must be citizens of the United Kingdom, or the Republic of Eire or a Commonwealth country. They should have experience in research and be under the age of 28 at the time of appointment. Fellows are appointed for one year in the first instance at an initial stipend of £1,821 per annum. The appointment, which is tenable in the Microbiology Unit, Oxford, may be extended for a further period of two years and there is provision for F.S.S.U.

Applications including relevant details and the names of two referees should be sent before April 1, 1974, to Professor J. Mandelstam, Microbiology Unit, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. (240)

UNIVERSITY OF CAMBRIDGE

BROODBANK FELLOWSHIPS

Election will be made in May 1974 to these Fellowships for the furtherance of research in Biochemistry or Biophysics with special reference to the Principles and Practice of Food Preservation. Tenure from a date and for duration to be determined but not exceeding total of three years. Fellow required to devote himself to full-time research in an approved subject normally at Cambridge. Candidature open, but preference to post-doctoral applicants. Fellow must become member of the University. Pensionable salary in the range £1,500 to £2,200 determined according to experience and qualifications. Compulsory superannuation. Grants may be given for research expenses. Allowed to give limited amount of paid teaching without reduction of salary.

Full details available from Secretary to the Managers of the Broodbank Fund, Department of Applied Biology, Downing Street, Cambridge CB2 3DX.

Candidates are advised to ascertain that there is a laboratory in Cambridge willing to accommodate research proposed.

Applications (ten copies) to reach the Registrary, University Registry, Old Schools, Cambridge, not later than March 1, 1974. Must outline research proposed and indicate bearing on principles and practice of food preservation. Must include full curriculum vitae, copies of papers published or references thereto and names and addresses of at least two referees. (192)

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF DEVELOPMENTAL BIOLOGY

Applications are invited for a Post-doctoral Fellowship and Research Scholarship to form part of a newly-constituted research group headed by Professor Brian Gunning.

POST-DOCTORAL FELLOWSHIP: Consideration will be given to suitably qualified applicants with experience combining electron microscopy with physiology or biochemistry, interested in ultrastructure of algal cells or of transport systems in higher plants, or applications of S.T.E.M. and energy-dispersive analysis of X-rays.

Post-doctoral Fellows are normally appointed for a minimum of one year and maximum of two. The salary range is $A8,698 to $A11,901 per annum and superannuation on the F.S.S.U. pattern is available. Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra.

The closing date is **February 11, 1974,** and applications should be sent direct to Dr. B. E. S. Gunning, Botany Department, Queen's University, Belfast 7BT 1NN, Great Britain. Applicants should ask three referees to write immediately to Dr Gunning.

RESEARCH SCHOLARSHIP: A Ph.D. scholarship is available for work on aspects of translocation in leaf tissues, involving investigations by conventional, quantitative, and analytical electron microscopy.

Research Scholarships are awarded for three years and provide a yearly tax free allowance of $A3,290 with extra allowances for dependent spouse and children. Return fares to Canberra and a grant for removal expenses are normally paid. Assistance with accommodation is available.

Application forms are available from the Acting Academic Registrar, P.O. Box 475, Canberra City, ACT, 2601, Australia, and should be returned completed by **February 8, 1974.** (196)

THE WELLCOME TRUST

TRAVELLING RESEARCH FELLOWSHIPS TO WESTERN AND EASTERN EUROPE 1974/75

Applications are invited from British research workers for the award of Wellcome-European Research Fellowships for 1974/75. These awards include the Trustees' special fellowships to Denmark, Germany, Hungary, Norway and Sweden.

The object of these fellowships is to encourage working visits to countries in Western and Eastern Europe by investigators in any branches of the natural and clinical sciences which have a bearing upon human or animal medicine. Candidates whose research is related to clinical problems will be given preference. These fellowships, which are normally for one year, are intended for graduates from the United Kingdom who already have some post-doctoral research experience. Stipends, according to age and experience, are within the range of £1,930 to £3,875 per annum. A special cost of living allowance applicable to the country in which the candidate wishes to work is given where necessary. Travelling and some incidental expenses are provided in addition.

The candidate must make his own arrangements with the department in which he proposes to work, and written evidence must be submitted confirming his arrangements. Application forms may be obtained from the Assistant Director, The Wellcome Trust, 52 Queen Anne Street, London, W1M 9LA. Completed application forms must be returned by March 31, 1974. (213)

CITY OF BIRMINGHAM POLYTECHNIC

THE BIRMINGHAM SCHOOL OF ARCHITECTURE

RESEARCH FELLOWSHIP

Applications are invited from scientists, architects and other suitably qualified persons, to undertake research in the Architectural Science Unit. The appointment is initially for one year but may be renewed annually for up to three years.

Salary scale: Lecturer II: £2,515-£3,243.

Full details and application forms (to be returned by February 1, 1974) from: The Staffing Officer, City of Birmingham Polytechnic, Room T.310, Perry Barr, Birmingham B42 2SU. (215)

POTATO MARKETING BOARD

POSTGRADUATE STUDENTSHIP AWARDS 1974

Applications are invited for the above studentship awards which are made to enable graduates holding first or upper second class honours degrees in pure or applied science to undertake further training so that they may conduct research at universities or research stations in this country on problems facing the potato industry. Applications are specially invited from graduates concerned with the production and marketing of the crop, the physiology and biochemistry of potatoes in relation to resistance to damage and improved quality, and the reduction of wastage caused by damage during the harvesting and handling of the crop.

The awards are tenable for up to three years at selected universities and research establishments in Great Britain and are valued at £800 per annum (tax free) plus educational fees.

Applications receivable by March 1, 1974, should be made on forms obtainable from the Secretary, Potato Marketing Board, 50 Hans Crescent, London SW1X 0NB. (178)

LECTURES AND COURSES

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF LANDSCAPE ARCHITECTURE

M.A. COURSE IN LANDSCAPE DESIGN

Applications are invited from graduates with good academic qualifications in disciplines related to landscape architecture. The course is of two years' duration and is recognised as giving exemption from Parts 1, 2 and 3 of examinations leading to professional membership of the Institute of Landscape Architects.

For details and application forms apply to the Faculty of Architectural Studies, The University, Sheffield S10 2TN. Please quote R 13/G. (182)

Glass Permeation Chromatography

WITH

CONTROLLED-PORE GLASS

CPG-10

COLUMN PACKING
MATERIAL

WHY CPG-10 IS PREFERRED OVER GELS:

- Greater Separation Range: 3,000 to 900,000,000 M.W. proteins and viruses; 2,000 to 12,000,000 M.W. polystyrenes.
- Controllable Pore Size: 75 to 2,500 Angstroms. Ten standard sizes in stock.
- Higher Flow Rates: up to 100X faster than soft gels.
- Stable Pore Size and Bed Dimensions: unaffected by eluant system, pressure, pH ionic strength, temperature.
- Chemically Inert: use exotic eluants (SDS), corrosive solvents, concentrated acids.
- Sharpest Available Exclusion Limits: pore diameter distribution less than ±10%.
- Readily Scaled-Up: no bed compaction, immune to biological attack, easily sterilized.
- Inorganic Support: large internal surface of controlled access for catalysts, biologicals, functional groups (aryl/alkyamines).

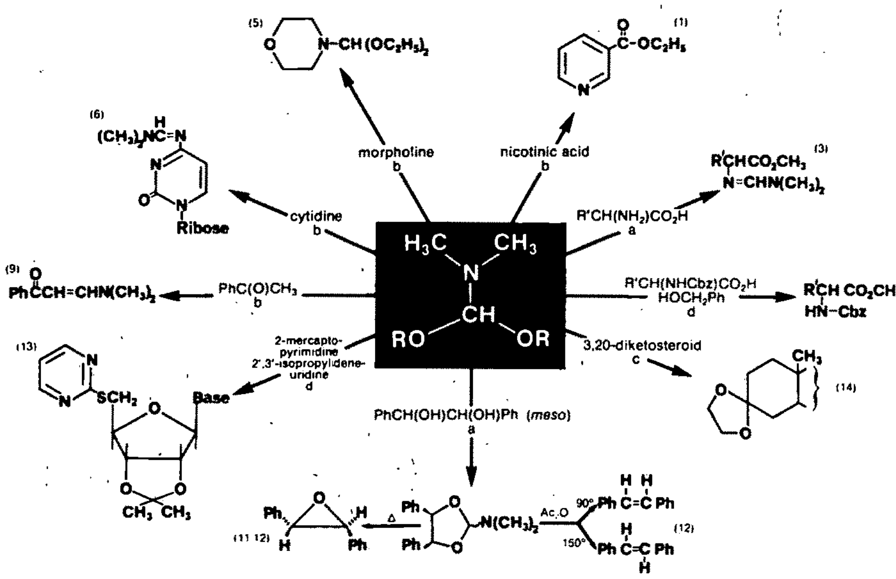
DMF ACETALS

A most versatile class of synthetic and analytical reagents

DMF acetals constitute a class of versatile synthetic and analytical reagents. With these acetals, carboxylic acids at room temperature give directly the corresponding esters;[1,2,3] amino acids form *N*-dimethylaminomethylene esters, suitable for glc analysis.[3] With **DMF dineopentyl acetal**, which is itself unreactive toward carboxylic acids but acts as a mediator, *N*-protected amino acids can be esterified with a wide variety of alcohols.[2,4] **DMF acetals** react with primary amino functions to yield *N*-dimethylaminomethylene derivatives.[5,6,7] The N^6-dimethylaminomethylene derivative of 9-β-D-arabinofuranosyladenine has anti-viral properties.[8] **DMF acetals** react with active methylene compounds such as acetophenone, ethyl cyanoacetate, 2-methylquinoline methiodide, etc.[5,9,10] Vicinal diols, *e.g.*, racemic and *meso*-diphenylethane-1,2-diol, cyclohexane-1,2-diol and 5α, 6β-dihydroxycholestane, are converted to epoxides and olefins.[11,12] The conversion of a nucleoside primary alcohol to a sulfide using **DMF dineopentyl acetal** has been reported. Raney nickel desulfurization gave the 5′-deoxy derivative.[13]

Many other reactions of **DMF acetals** are documented in our technical information bulletin which is available on request.



Reagents: a = $(CH_3)_2NCH(OCH_3)_2$; b = $(CH_3)_2NCH(OC_2H_5)_2$; c =  ; d = $(CH_3)_2NCH[OCH_2C(CH_3)_3]_2$

LIFE SCIENCE INFORMATION SERVICE
. . . NATURALLY.

BIOSIS is the largest information service for the life sciences. From this broad reference base are derived **BIOLOGICAL ABSTRACTS**, **BIORESEARCH INDEX** and twenty-two other derivative publications and services. With your subscription to **BIOLOGICAL ABSTRACTS**, you receive twice monthly abstracts and indexes gathered from more than 8000 journals originating in more than 100 countries throughout the world. This annually amounts to more than 140,000 research papers, arranged for publication under 623 subject categories in **BIOLOGICAL ABSTRACTS**. Every issue of **BIOLOGICAL ABSTRACTS** provides you with the broadest and most diverse source of abstracted information in your discipline. Write today for your Guide to the Indexes and Subject Classification Outline.

First Announcement

International Society for Psychoneuroendocrinology

V^th^ International Congress

on

"HORMONES, HOMEOSTASIS AND THE BRAIN"

Utrecht, July 24-27, 1974

Rudolf Magnus Institute for
Pharmacology, Medical Faculty,
State University of Utrecht,
Vondellaan 6, Utrecht,
The Netherlands

Topics

- **Early Hormonal Influences on Ontogenesis of Behavior and Brain Development**
- **Hormones and Sleep**
- **Central Regulation of Homeostasis**
- **Hormones on Learning and Memory Functions**
- **Releasing Hormones on the Central Nervous System**

The Congress will comprise formal symposia on these topics dealing with observations in animal and man. In addition, sessions of short communications will be held, preferably on the symposia topics.

The meetings are open to members as well as to non-members of the Society.

Instructions for preparation of abstracts, copies of the announcement, and forms for registration and hotel accomodation may be obtained from the Organizing Committee at the above mentioned address.

Deadline for registration:
MARCH 1, 1974.

Deadline for submitting abstracts:
APRIL 15, 1974.

Matters Arising 243

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système Internationale. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (a) is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Cambridge University Press

Free Radical Chemistry

D. C. NONHEBEL and J. C. WALTON

A comprehensive review of the development of free radical chemistry up to the present time, presenting a description of the methods available for their study and leading up to a discussion of the important reactions. An important feature of this book is that it brings together the physical and organic branches of the subject.

A work of reference for all chemists that will be found on the shelves of research workers in universities, technical colleges and in industry.

£15.00 net

An Introduction to the Ionosphere and Magnetosphere

J. A. RATCLIFFE, F.R.S.

A volume for postgraduate students and research workers in ionospheric physics, presenting in a manageable form the essentials of a very complex field of study.

The first part of the book discusses how the structure and behaviour of the ionosphere and magnetosphere are determined by the nature of the gases in the atmosphere and of the solar radiations to which they are subject. In the second part the author describes the physical principles underlying some of the processes occurring in the ionosphere and some of the experimental methods which have been used to investigate them. **£4.00 net**

A programmed learning text:

Introducing Root Locus

PETER DRANSFIELD and DONALD HABER

The root locus technique is one of the useful ways of analyzing control systems included in undergraduate courses in control engineering. This programmed learning text will instruct the student as to the nature of a system's root locus, its construction, its interpretation and how to use it as a design aid.

The course is designed to run over the equivalent of six or seven class periods for undergraduate students of chemical, electrical and mechanical engineering in universities and technical colleges. **£2.00 net**

The first book in a new series:

CAMBRIDGE SOLID STATE SCIENCE SERIES

The Solid–Liquid Interface

D. P. WOODRUFF

In this, the first book of a new series, the author describes the basic physical processes which underlie all of the important techniques involved in crystal growth from the melt, irrespective of the special problems of individual materials and particular experimental techniques. The basic background physics associated with solidification and melting are discussed in order to help the student understand better why certain precautions or methods are necessary to grow a single crystal or make a better casting. **£3.30 net**

An Introduction to Electromagnetic Theory

P. C. CLEMMOW

Classical electromagnetic theory occupies a prominent place in undergraduate courses in physics, applied mathematics and engineering but, with the widening of many syllabuses, the subject has to be taught in a less leisurely way than was possible in the past.

Dr. Clemmow has written a crisp and selective introductory account for first and second year level undergraduate students, concentrating on field theory and using standard vector analysis. Rationalized MKS (S.I.) units are used throughout. Problems for the student are given at the end of each chapter.

Hard covers £5.40 net
Paperback £2.40 net

The Large Scale Structure of Space–Time

S. W. HAWKING and G. F. R. ELLIS

The authors develop a picture of the universe, its origin and its possible end on the basis of Einstein's General Theory of Relativity. They show that it makes two remarkable predictions: first, that the final fate of massive stars is to collapse with the formation of a black hole in which all the matter is trapped by colossal gravitational forces, and secondly that there is in the past a singularity where our present laws of physics break down and which may be construed as a beginning to the universe.

The book also surveys recent developments in the global theory of relativity and contains a considerable amount of previously unpublished material.

Volume 247 January 25, 1974

Seven questions for the energy secretary

Britain now has a Department of Energy whose Secretary of State is Lord Carrington, previously Secretary of State for Defence. The brief of this new department is, in the words of the Prime Minister, "to concentrate on the development of the coal industry on nuclear power and on our offshore oil and gas resources at home, as well as on those tasks of working together with other oil-consuming countries and with the oil-producing countries on the international aspects of the energy problem".

The following energy issues will ultimately deserve his or his successor's attention.

How permanent is the department to be? It is unlikely that the problem of finding adequate, reasonably priced energy sources is going to go away before the turn of the century. Many scientists and technologists could become enthused by the thought of a long term commitment to a strong government department pursuing such desirable objectives as rethinking energy strategy. They could not face, however, being pushed around from ministry to ministry each time the Cabinet was reshuffled.

Can energy be removed from the political arena? There are many aspects of energy policy which merit serious discussion but the subject can easily become a political football. The inferior quality of the recent Commons debate on the fuel shortage does not bode well for informed non-partisan discussion in the future. Lord Carrington is, of course, a political creature holding simultaneously the post of Chairman of the Conservative Party. At the moment he is probably as obsessed with the thoughts of election strategies as with energy policy and in the long run it is desirable, assuming he wishes to remain as Secretary of State for Energy, that he does not divide his talents, particularly with such a politically exposed position.

Can some order be brought into research funding? Some weeks ago we reported on an energy strategy devised for the United States (**246**, 370; 1973). An important feature of it was that it was not intended to be competitive. Funding for coal was not to be at the expense, say, of funding for validating the nuclear option, nor was the coal industry in the process of its research expected to denigrate the nuclear industry. A strong impression left by many British pronouncements is that developments are largely made for this very purpose. It is therefore highly desirable that an urgent new look at funding mechanisms be made, in order to impose, if necessary, a degree of overlordship by an energy department.

Consequent on this, why not a think tank? Britain is not short of experts in almost all individual fields of energy research and use. It is, however, desperately lacking in people with wider vision. The reasons need not be repeated here. Yet without such people, and they should not necessarily be civil servants, an unreasonable load is placed on a minister in making decisions. A think tank would at least be a means of educating a wider range of people in strategic thinking.

Cannot conservation efforts be improved? Remarkably little has been done in the way of education for saving fuel and yet there are very attractive opportunities. Why does Lord Carrington not visit a power station and invite, in front of television cameras, all viewers to turn off something electrical? The drama of a meter needle moving under the influence of one's own action in the home would rival Mr Geller's activities.

How will Britain react to the Kissinger energy initiative? At the same time that it was being 'warmly welcomed', Britain and France were doing bilateral deals wherever possible—deals which, however desirable in the short term, cannot have a long term future within the spirit of international cooperation. However cynical one may be about the United States leading such an initiative while consuming energy so greedily and often wastefully, in the long run someone had to recognise that energy is so much a supranational and supra-oil company affair that it has to be dealt with internationally.

And, this being so, should Britain take steps to safeguard the interests of other countries, particularly developing ones, for whom increased energy prices are much more economically damaging than for industrialised countries? The early formulation of an international attitude to energy is possibly the most urgent need there is today. It will be of great interest to see whether the big energy consumers can see beyond their own industrial landscape.

100 years ago

Our country depends for its high position among nations, not only on its resources in coal and iron, but also, and more securely, on the mental capacity of its people, whose peculiarity is that they have the power of always using the resources at their disposal to better advantage than any others. We in nearly all cases have taken the lead in invention. A

From *Nature*, **9**, 237, January 29, 1874.

Is population a ministerial responsibility?

Mr D. R. Cope of the Institute of Planning Studies, University of Nottingham, questions the need in Britain for a minister with special responsibility for population matters.

THE announcement, by the Prime Minister, Mr Edward Heath, just before Christmas that Mr James Prior, Lord President of the Council, is to be minister with special responsibility for population matters means that one of the major recommendations of the Population Panel, set up in November 1971, has become government policy (*Report of the Population Panel,* HMSO; 1973). Population is by no means Mr Prior's only responsibility, as several pressure groups campaigning for a separate ministry were quick to point out, but his appointment raises the question of what are the areas of action open to a minister for population and what should be his priorities.

As the panel noted, quite a wide range of government activities, especially health, social welfare, fiscal and planning policies, may have an impact on population trends, but to date no government has formed policies with particular regard to the possible impacts. Is this situation likely to change?

The current demographic position in Britain is that no serious economic or social problems which could be directly attributed to either its population size or growth rate are likely to emerge in the next thirty or forty years. Present fertility behaviour will, of course, have an effect on population levels in the first decades of the next century and a minister of population will be concerned with what are, for economists and social planners, very long term futures. For politicians, such a long term concern is almost unprecedented and the potential unpalatability of a current policy designed to affect the demographic situation in the next century would be so great as to deter any government from incorporating an overt population policy in its programme of action.

Will the British government pronounce an opinion on an 'optimum' national population? The considered opinion of most academic demographers, such as Professor D. V. Glass of the London School of Economics, is to dismiss the concept as providing no useful base for policy making. Different criteria produce a congery of optima, many of which conflict with each other. Like the legendary castle which always stayed on the horizon no matter how far or fast travellers rode towards it, an optimum population, if it could be defined, would be unobtainable. In the time taken to achieve a stated population, external circumstances would almost certainly have altered to give rise to another optimum.

The major field of potential action in population matters is in family planning policy. The present government has already incorporated an extended service in the health service reorganisation bill, though it was motivated as much by considerations of general social welfare as by any demographic consequences. It is well known that even if every birth in Britain were to be 'wanted'—if there were to be perfect use of contraceptive facilities—current family size patterns mean that the population would continue to grow. Demographically, a policy of freely available contraceptive facilities and a free abortion service to take care of cases of contraceptive failure or unavailability would have the greatest potential impact. Abortion can be a very effective agent in influencing population patterns but the sensitivity of the subject is again likely to deter governments from too firm or blatant a policy relying on it.

There are really only two areas in which a population minister could identify immediate action needs: in demographic research and in publicity and information. Despite recent increases there is still far too little serious demographic research being carried out in Britain. Over the past few years many unsubstantiated assertions have been made on the relationships between population and the economy and environment, and about the impact of human numbers and densities on social and psychological well being. The need now is for research to test some of these interrelationships, especially factors affecting fertility behaviour. Demographers are also hopeful that Mr Prior's appointment will make it difficult for the government to cancel the proposed 1976 census on the grounds of economy, as a ten year intercensal gap is manifestly inadequate for determining changes in trends.

The Population Panel placed great emphasis on the need for government action on publicity and information about population trends and patterns. Obviously, a family planning service will be fully successful only if all those who could use it are aware of it and do use it. The panel, however, looked beyond such simple publicity and argued the necessity of bringing home to the public the need to consider the aggregate consequences of their family building behaviour, despite the possible conflict of these consequences with individuals' preferences. This reminds one of government attempts to do much the same in the context of income restraint and no doubt the public response would be very similar.

James Prior, Lord President of the Council

It will be interesting to see how long the position of minister with responsibility for population matters survives, given the very limited possibilities associated with it. Demographic trends may even rapidly make it superfluous if the position is seen as being specifically concerned with problems of population growth. As yet the post-1964 downturn in the numbers of live births shows no signs of reversing and despite allusions to the 'New York blackout syndrome' (which was a myth anyway, according to Udry, *Demography,* **7**; 1970), current economic difficulties may well lead to an even greater decline in birth numbers with couples avoiding additional expenses by postponing births. Widespread advance warnings of economic rigours and the much greater use of the oral contraceptive pill mean that Mr Prior will not have to concern himself with a marked upturn in births in the last quarter of this year.

international news

Credibility gap worries US energy office

Colin Norman, Washington

After being deluged with dire warnings about the energy crisis that was supposed to hit the United States this winter, many Americans are now beginning to wonder whether there is a crisis at all, or whether the whole thing is an elaborate plot by the oil industry to drive up prices and profits. So far, there have generally been adequate supplies of gasoline and heating oil, cities are still brilliantly lit at night by hideous advertising signs, and life is proceeding more or less normally for most people. About the most tangible sign of energy shortages is that gasoline and heating oil have increased in price.

According to William Simon, Director of the Federal Energy Office, his biggest problem in the next few months is the growing public scepticism about the energy crisis. He is anxious because such scepticism could lead to backtracking on conservation measures which have so far turned out to be remarkably effective in curbing demand, and that in turn could precipitate a full-blown crisis before the summer arrives. And the problem of maintaining public support will become even more difficult once Arab oil again starts flowing into the United States. In fact, the Administration is so concerned about the matter that President Nixon made a radio address last weekend during which he warned that "if we permit ourselves to slack our efforts, to slide back to the wasteful consumption of energy, then the full force of the crisis will be brought home to Americans in a most devastating fashion, and there will be no longer any question in anyone's mind about the reality of the crisis".

The scepticism stems not only from the fact that there has been little discomfort so far in the United States, but also from a series of reports of record profits in the oil industry, rumours of tankers sitting outside ports waiting for oil prices to creep up before they unload their cargoes, and allegations that storage tanks at refineries are brimming with heating oil. But perhaps the most damaging blow to the credibility of the crisis is the growing public awareness of the fact that the government has been forced to rely almost exclusively on the oil industry itself for statistics about production and stocks of oil. As Mr Silvio O. Conte, a Republican Congressman from Massachusetts, put it last week, that is like "putting a fox in to watch the chicken coop".

The Administration is thus beginning a campaign to assure the American public that the crisis is real, and that conservation measures are still necessary. First, President Nixon promised in his radio message that he will send a bill to Congress which would impose a windfall profits tax on oil companies to force them either to turn over excess profits to the government or to invest them in exploration for new sources of energy. And second, the Administration is sponsoring a bill which will, in Nixon's words, "require the oil companies to provide a full and constant accounting of their inventories, their production, their costs and their reserves". And, in the meantime, Simon has ordered a full audit to be conducted on the companies' figures. Those measures should, at least, help dispel some of the public distrust over the figures.

But, although the government has been relying on industry data for its analysis of the energy situation, there is still good reason to believe that the shortages are real, and are not solely the product of an inspired public relations exercise by the oil companies. As S. David Freeman, Director of the Ford Foundation Energy Policy Project, suggested last week, the companies have certainly been making a lot of money out of the situation, and the data they have supplied through the American Petroleum Institute may not tell the whole truth and nothing but the truth, but he suggests that they still indicate the need for gasoline rationing to be imposed in the spring.

And there is also good reason to believe the Administration's assertions that if the American public slackens in its conservation efforts, a severe crisis could still develop. For one thing, a variety of data supplied by the electricity industry, by the oil companies and by independent analyses all attest to the fact that conservation efforts have been remarkably successful in decreasing demand, even if the unusually warm weather in the last quarter of 1973 is taken into account. And for another, a lot of oil has been flowing into the United States through the embargo, and this is now beginning to dry up—and even if the embargo is suddenly lifted, it will take several weeks for the oil to reach United States ports.

One of the most direct indicators of demand for energy is the amount of electricity supplied to consumers. According to data produced by the Edison Electric Institute, at the end of last year, consumption of electricity throughout the United States was averaging about 1.5% below that of a year previously. Moreover, during the week ending on January 12, demand dropped by 4.1%. Compared with an expected increase of about 7%, those figures show a very substantial decrease in demand.

In his radio address last weekend, President Nixon also cited a sheaf of statistics to show that demand for other forms of energy has declined equally dramatically. Consumption of gasoline in December was reduced by 9% below expected levels, for example, natural gas consumption was down by 6% compared with last year, and he also referred to a study in the North East which showed that some 19,000 households had reduced their heating oil consumption by an average of 16% compared with last year, even after adjustments had been made for the warmer weather.

The Administration still reckons however, that during the first three months of 1974, supplies of oil will fall short of previous demand by about 2.7 million barrels a day, or about 15%. This must be accounted for either by rationing or by conservation measures. Heating oil is already being allocated to parts of the country which are especially hard hit by the oil embargo (in other words, it is being rationed at the wholesale level), and last week the Federal Energy Office published details of a gasoline rationing plan which will be brought in if necessary, although no earlier than March.

In any case, President Nixon declared last weekend that he is opposed to gasoline rationing, and will avoid bringing it in if at all possible. He said, for example, "if this voluntary cooperation (in reducing consumption) continues, . . . we can avoid gas rationing this spring . . . and you can be sure that I will do everything in my power to achieve the goal of avoiding gas rationing."

Pollution research in a sorry state

Colin Norman, Washington

THE federal government's research and development programmes for cleaning up water pollution are starved of money, poorly managed and badly coordinated, according to a massive study carried out by the General Accounting Office (GAO). Unless the programmes receive more funds, the GAO said in a report made public last week, the goals set by the 1972 Water Pollution Control Act will not be met. Charges of financial undernourishment are commonplace in Washington, but in this instance they gain considerable credibility from the fact that the GAO, which is an investigative agency of Congress, has no axe to grind since it does not have a direct stake in the matter.

The Water Pollution Control Act, which was passed by Congress in December 1972, specifies that waterways in the United States should be clean enough to swim in by 1983, and that no pollutants at all should be discharged into navigable waters by 1985. Those are tough goals to meet, and they will clearly require massive investment of funds in sewage treatment plants. They will also require a vigorous programme of research and development on new control technologies.

Far from pursuing a vigorous programme, however, the Administration has cut some research budgets and failed to disseminate results from the studies which are being carried out. Moreover, the GAO charges that no overall strategy for research and development has been worked out by the Environmental Protection Agency, and the research is therefore not sufficiently geared towards meeting the goals specified in the Water Pollution Control Act.

Between July 1969 and June 1973, about $495 million was spent by twelve federal departments and agencies on water pollution research, some $238 million of which was spent by the Environmental Protection Agency (EPA). Although the EPA is supposed to be the focal point in the federal government for pollution control research and for enforcing federal environmental laws, its water pollution research budget was actually cut by the Administration in the 1973 fiscal year, from about $50 million to $42 million. Meanwhile, the water pollution research programmes of other agencies doubled between 1969 and 1972, increasing from $36 million to $71 million.

A prime objective of the EPA's research programme should be to minimise the costs of treating municipal sewage, because huge sums of money will be spent in the next few years on treatment plants—the 1972 Act, for example, authorises expenditures of $18,000 million between 1973 and 1975 for grants to help in the construction of sewage plants. A small percentage saving from research would clearly save large sums of money.

But the GAO report points out that although $3,000 million was earmarked for municipal sewage grants in 1973, only $9.5 million was earmarked for the development of control technologies. That translates to an investment of only 0.3% in research, and compares with a rate of 8% in the Department of Transportation's urban mass transportation programmes, and a rate of about 4% in industry, the GAO report notes.

A similar situation exists in another important EPA research programme—research aimed at determining how pollutants get into water, what happens to them, and what their effect is (so-called process and effects research). The GAO found that because of funding limitations and poor management, important research needed to establish water quality standards has been delayed, and research on thermal discharges has been inadequate. As far as the latter programme is concerned, the GAO report notes that thermal pollution is likely to be a rapidly growing problem as the number of power plants increases, but research is proceeding slowly, and according to the director of one EPA laboratory, the agency has not even begun to solve the thermal pollution problems likely to be present in 20 years' time.

The GAO also found that there is a lack of coordination between the government's research and that conducted by industry, to such an extent that "we were informed (by representatives of industry) that industry was reluctant to reveal to EPA the level of technology developed to control pollution because (EPA) might speed up its enforcement action and industry might suffer a financial loss".

What needs to be done to alter this sorry state of affairs? Apart from increasing expenditures on research and development, the GAO report recommends that EPA should draw up a research and development strategy which would estimate the amount of money needed to meet the goals set out in the Water Pollution Control Act. The Office of Management and Budget should designate a federal agency as the focal point for coordinating research, and for disseminating research results, and ensure that EPA gets full cooperation from other agencies in drawing up its research and development strategy.

As for the Congress, the GAO suggests that since it is doubtful that waterways will be cleaned up by 1983 with present research funding levels, some thought should be given to increasing research appropriations. The

---

Sherman quits NIH

Colin Norman, Washington

A TOP official at the National Institutes of Health has resigned in frustration over the Administration's policies for biomedical research in general and for NIH in particular. Dr John Sherman, Deputy Director of NIH since 1968, and an NIH employee since 1953, will be leaving early in March to join the staff of the Association of American Medical Colleges, a Washington lobbying organisation.

Sherman said in a telephone interview last week that he has resigned "because of a number of tangible and intangible things" which are eroding the prestige of NIH and "making it a less attractive place to do research in". Chief among Sherman's complaints are the fact that the Administration has cut the number of personnel positions at NIH, and because he finds a lack of understanding between officials in the agency and administrators in the Department of Health, Education and Welfare.

As far as staffing is concerned, Sherman pointed out that personnel have been cut back at a time when the budget has been expanding, and when greater emphasis is being placed on contract research as opposed to grants. Contracts take more time to administer, and therefore require more staff.

For some time, there has been general discontent at NIH over policies dictated by the Nixon Administration. Many of the complaints have revolved around budgetary problems, because the Administration cut many of the institutes' research budgets last year, and also because Congress and the Administration failed to agree on a budget for the agency for almost 18 months. But Sherman's complaints go deeper than simple lack of money. "There is a sort of a sense of negativity (in the Department of Health, Education and Welfare), and a lack of understanding between us and the decision-makers", he said, and many of the frustrations stem from the strict management control that the Administration is trying to place on basic biomedical research.

Sherman first joined NIH in 1953, he has been an Associate Director of NIH for Extramural Programs, and was appointed Deputy Director in November, 1968. When Dr Robert Q. Marston resigned as NIH Director a year ago, Sherman was appointed acting director for some six months.

problem is, however, that the Administration needs to be persuaded to spend money for water pollution control which has been earmarked by Congress. So far, the Office of Management and Budget has released less than half of the money for sewage treatment grants which Congress authorised in the 1972 Water Pollution Control Act.

New cyclotron for neutron therapy

John Hall

Because of Hammersmith Hospital's success in the use of neutron therapy for the treatment of cancer a second British hospital is to be supplied with a compact cyclotron. The Medical Research Council (MRC), the Scottish Home Office and Health Department, and the Cancer Research Campaign will jointly finance a unit costing £819,000 at the Western General Hospital Edinburgh, which should be ready to treat patients by the summer of 1976. Hammersmith Hospital has been a world leader in the use of fast neutrons for cancer treatment and if clinical trials at both centres are as successful in the future as they have been to date, the Department of Health could well be persuaded to make a big investment in this type of treatment.

The first cyclotron in the world to be entirely devoted to medical research was installed at Hammersmith in 1952. After extensive research in the laboratory, clinical trials in the treatment of advanced cancers were started in 1969. Randomised trials conducted alongside conventional programmes of X-ray treatment showed promising results in the treatment of cancers situated in the head and neck, although patients often died from secondary cancers which had spread before the primary source could be destroyed.

Radiotherapy in this area works on the principle that malignant tissue is more sensitive than healthy tissue to destruction by X-rays and γ rays. Where there is a low oxygen concentration in the tissue, caused perhaps by the presence of the tumour, there is, however, a reversal of the effect and the cancer is often able to grow again after partial destruction. The effectiveness of neutron therapy depends on the ability of the neutrons to destroy cancer cells even in the absence of oxygen.

After closely following the trials at Hammersmith, workers in the United States decided a year ago to adapt three of their large cyclotrons used in physical research for cancer treatment and other centres will be established in France, Germany, the Netherlands and Japan.

The Edinburgh cyclotron will produce neutrons with twice the energy available at Hammersmith and will be made more versatile by the inclusion of a steering device which will allow a site to be attacked from several different positions.

The new installation will be an outstation of the MRC's Hammersmith Cyclotron Unit, which is directed by Mr Derek Vonberg. The clinical programme will be directed by Professor W. Duncan of the Department of Radiotherapy (University of Edinburgh) and the clinical trials (which at Hammersmith were led by Dr Mary Catterall) will be supervised by a special committee on neutron therapy of the MRC, on which the Cancer Research Campaign will be represented.

What is wasted?

Even when we can actually lay hands on fuel for motor systems and power generation we waste a vast amount of the energy potential contained in the raw materials. In his Inaugural Lecture at the University of Leeds, Professor Alan Williams examined Britain's power station wastage and compared the fuel efficiencies of various methods of transport.

He finds that the average power station supplying 2,000 MW of electricity also produces 4,000 MW in steam and warm water which is generally not put to any use, so that even during the energy crisis Britain can only benefit from 45% of all fuel actually burnt.

The average engine is still less than 20% efficient in converting fuel into useful motive power and a comparison of different transport methods in terms of passenger miles per gallon showed a fully loaded train to be ten times more efficient than a jet aircraft and fifteen times more efficient than Concorde.

Professor Williams, Livesy Professor of Fuel and Combustion Science, considers that the efficiency of liquid fuel engines and power stations is capable of being improved by a further 10%. Of the 25,377,000 tons of liquid fuel used for transport in 1972, something like 74% was used by road vehicles operating at low efficiencies. Although in theory a diesel engine might have a thermal efficiency of 37% and a petrol engine 25% (17% in the case of a Wankel), in fact only 15% to 20% of their fuel is converted into useful energy.

Bringing NASA down to Earth

Colin Norman, Washington

Buried in the pile of bills, resolutions and impeachment motions facing members of the US Congress who returned to Washington last week is a little-noticed item which could radically alter the National Aeronautics and Space Administration (NASA) and create yet another new focus for federal science policy-making. The bill, which was introduced into the Senate last September, is likely to be the subject of public hearings in February and the topic of considerable debate thereafter.

Called the "Technology Resources Survey and Applications Act" and numbered S2495, the bill would give NASA some $200 million a year to help apply science and technology to pressing domestic problems, partly by enlisting the help of the depressed aerospace industry. It would also establish a Cabinet-level committee to survey the United States' scientific resources, and to plan how those resources could best be used to improve such items as health care delivery, sewage treatment and other domestic services.

The bill would thus greatly extend NASA's range of activities in fields other than space research, and it would add considerable impetus to the much-discussed move toward spending federal research and development dollars on more socially useful projects. But it is also likely to run into opposition from the Administration, and its prospects are uncertain.

In many respects, the bill is similar to Senator Edward M. Kennedy's National Science Policy and Priorities Act, which was passed by the Senate in 1972 but which died from neglect in the House of Representatives. Kennedy's bill would, however, have placed responsibility for supervising and sponsoring such domestic research and development programmes in the National Science Foundation—at best an unlikely location, but one which would have placed the whole effort under the jurisdiction of Kennedy's NSF Subcommittee. NASA is clearly a more logical home for such an enterprise because it already has an office concerned with technology utilisation, but even so, some bureaucratic turf fighting would be inevitable if the bill were passed in its present form.

For one thing, the National Science Foundation is now supposed to have responsibility for surveying the government's efforts in science and technology and for advising on how federal money should be spent on research and development. It would be unlikely to yield a good part of that responsibility to the Cabinet-level committee proposed in the bill. And there is also the problem that the Administration would not take kindly to such a large spending commitment in such difficult financial times.

What are the chances that the bill will be passed? Staff members of the Senate Committee on Aeronautical and Space Sciences are hoping to get some hearings underway in February. But one problem is that the bill has also been referred to the Senate Commerce Committee whose chairman, Warren Magnuson, is the bill's chief sponsor. Unless some formula can be worked out for both committees to consider the legislation simultaneously, its passage through the mill will be slowed down. Moreover, even if the bill is passed by the Senate before Congress adjourns for the October Congressional elections, there is no sign of interest in the House of Representatives. The House Science and Astronautics Committee, for example, has its plate full with energy matters, and would be unlikely to take up the bill in time to get it passed by the House this year.

Nevertheless, the bill is likely to spark considerable discussion in the scientific community, just as Kennedy's bill did two years ago.

No astronomical ghosts laid

Edward Phillips

Dr David Evans, the Welsh-born optical astronomer, sees himself as the *enfant terrible* of British astronomy, although some would say *vieux terrible*. After many years in British and South African astronomy he now works at the University of Texas, but last week he was in London and at the monthly meeting of the Royal Astronomical Society. And for once the society forsook its normal academic fare to allow Dr Evans to present his views on the management of British optical astronomy.

Dr Evans seemed to be attributing what he called "the depressed state of British optical astronomy" to two factors. First, he blamed "overbureaucratisation" which he said resulted in the voice of optical astronomy emanating from administrators instead of from the scientists working at the observatories. And, second, he recognised "an unfortunate relationship between optical and theoretical astronomers", there being a tendency to disparage any work which originates too far from what he termed the Cambridge-Caltech axis.

All this was greatly enjoyed by the younger astronomers present, while their elders were notably less amused. But after this cracking start Dr Evans lapsed into a panegyric for astronomy at the University of Texas, in particular the McDonald observatory at Fort Davis which he put forward as the ideal site for the proposed Northern Hemisphere Observatory.

In the circumstances the president of the society, Professor D. E. Blackwell, was probably being benevolent in ruling that there was insufficient time for discussion, although Sir Bernard Lovell was allowed to say a few words in support of British optical astronomy.

Unfortunately, though, this meeting, which could have served as a much needed exorcism after all the troubles that have beset British optical astronomy, fell far short of achieving any useful purpose. The Royal Astronomical Society is, however, planning a meeting where officials of the Science Research Council will be able to explain the latest policies in astronomy. Maybe this will be the occasion for casting out a few devils.

Keeping a non-stop world

Having sacked the Earth to the point where (arguably) we are virtually bankrupt of fossil fuels, it is good to see a politician draw the line at actually stopping the planet from spinning in the pursuit of new energy sources.

In a House of Commons debate on tidal power British Member of Parliament Mr Tam Dalyell asked whether or not the government was prepared to talk about tidal energy at an international level since, he observed, there is a serious question of reduced Earth spin if several countries embarked on such schemes. Mr Dalyell also asked whether or not there would be adverse effects on the ocean bed and whether such fears need be harboured if there were a two-basin estuary scheme.

His point in raising these questions, apparently, was to demonstrate that people who proposed tidal energy schemes were aware of the attendant anxieties and, he submitted, it would be silly not to express a certain sensitivity towards them. Which of course is true, though, it must be added, it would not be ever so silly since the estimated time required for tidal harness schemes to stop the Earth's spin is something in the region of 10 million years.

correspondence

Energy

Sir—The United States is feeling the energy pinch and is beginning to realise that pertoleum, along with other critical materials, cannot last forever. This is causing us to intensify our efforts toward alternate energy sources and to examine how we can reduce consumption and increase reclamation. It is also causing critics, both locally and abroad, to accuse America of the 'mindless' utilisation of energy (*Nature*, **246**, 116; 1973). Statistics are quoted about our small population using a third of the world's energy and implying that this energy is mostly wasted or used for personal comfort and enjoyment.

I will concede that we have wasted resources, most recently in Vietnam, and that we drive too much, have too much throw-away packaging, and more air conditioning than we really need. But I argue that the majority of the energy has been used productively. America has exported energy to the four corners of the world in the form of wheat, rice, soy beans, cotton, lumber, machine tools, tractors, airplanes, locomotives, and medicine.

We have exported American know how, fed and clothed both allies and enemies after World Wars I and II, and rebuilt their factories. Their factories today are more modern than our own. For much of this we have received little or no payment—yet these activities have caused depletion of our soil, natural resources, and treasury. I wish our critics in England, France, Russia, Germany, Japan, China, and the Middle East would remember some of these things when preparing their editorials.

In some instances we may have been guilty of exploitation and of not minding our own business. But, when it comes to energy, perhaps we have not used more than our fair share, considering the billions of BTU's used to make or grow the products we have given away.

Yours faithfully,

E. A. Aas

New view of deep earthquakes

Conventional wisdom has it that an earthquake is a sudden rupturing across a fault plane, the total duration of the event being roughly the maximum distance along which slippage occurs divided by the rupture velocity of several kilometres per second. It is also very widely believed that a 'mechanism' can be associated with every earthquake—a quadrantal distribution of rarefactions and compressions related to the orientation of the fault plane and the slip vector. A paper by Dziewonski and Gilbert in this issue of *Nature* (page 185) raises some fascinating questions about this simple and highly successful model of earthquakes. It seems that deep quakes can be preceded by over a minute of slow compression.

For the past ten years it has been possible to study radiation patterns of earthquakes by the use of long period (10 to 100 s) seismometer recordings of body waves. The signal begins sharply—it seems to have both a precise starting time and an unambiguous polarity. The observed distribution of these polarities over a notional sphere surrounding the quake is in almost all cases entirely concordant with a 'double-couple' model of the event. The few exceptions are probably explicable in terms of propagation anomalies. True, Knopoff and Randall looked into the possibility that body wave polarity distributions from deep focus earthquakes were somewhat removed from those of the simple model, but their evidence was not very strong. Almost all seismologists regard the model outlined above as an adequate description of the observed seismic source.

Nevertheless, there are some nagging problems. Plate tectonics explains shallow earthquakes as a manifestation of rubbing, slipping and cracking near plate boundaries and for such events the double-couple model of the source is entirely appropriate. But when plates descend beneath island arcs they presumably end up by being assimilated at a depth of about 700 km. During this descent into the mantle the lithospheric material has in all probability to undergo phase changes. The surrounding mantle is believed to contain large phase transitions at 400 km and 600 km depth at each of which physical properties suffer a change of several percent. Since there are earthquakes at all depths in the descending plate, the obvious question is whether deep events, although apparently double-couple in nature, contain any constituent, say, of compression that might be associated with an explosive phase change. Dziewonski and Gilbert's results indicate that this is a real possibility.

For several years the authors have been analysing the oscillations of the Earth which follow very large earthquakes. They and others have developed highly sophisticated methods for extracting signals at periods of up to 1 h from the hundred or so seismic stations around the world. As a result of this work the broad structure of the Earth's interior is known with some confidence. Until recently, however, the inversion process was simply from the observed eigenfrequencies to physical structure. There is more available, however—amplitude and phase of each eigenfrequency is accessible with careful processing. This permits inversion for the generating function, or source mechanism as a function of time. The solution from body waves for the source mechanism is a high frequency one, but free oscillations cover a lower frequency range. Does the earthquake look similar in appearance at lower frequency?

The answer is that it does not. Dziewonski and Gilbert look at two deep earthquakes in South America. They find, not surprisingly, that to the extent that their solutions can be interpreted as double couples they are in agreement with body wave solutions for the mechanisms. There seems, however, to be a substantial constituent of non-deviatoric stress released and this stress is dominantly compressive. Furthermore, the inversion indicates clearly that compressional energy is in both cases released from the vicinity of the event for at least 80 s prior to what is more conventionally called the earthquake—the time of double-couple radiation of high frequency energy. The release of stress seems to be very smooth and thus there is no record of high frequency signal from it.

This is a most exciting result. If deep focus earthquakes can have a compressive precursor then this may be a transition to a more dense phase. The authors point out that it is entirely possible that it is the heat generated by this transition which causes local melting and triggers the quake along a lubricated slip plane. They further suggest that there may be occasions when the compression proceeds without triggering a slip.

Care must be taken in contrasting deep and shallow quakes, for both of which precursory signals have now been recorded. In both cases it seems that earthquakes can occur through lubrication of the fault plane. For shallow events the lubrication seems to come through a long term change in the distribution of fluids in the source reigon. For deep events, if the authors' speculation is correct, the lubrication would arise from exothermic phase changes. Doubtless more will be heard of deep earthquakes in the next year or two.

D. D.

T cell Ig receptors— to be or not to be?

There are few subjects of investigation in cellular immunology which have attracted more controversy than the nature of the receptor for antigen on thymus-derived (T) lymphocytes. A good illustration of this is to be found in several recent articles, two of which by Roelants and colleagues, have appeared in *Nature* (**247**, 104 and 106; 1974).

The central question is whether T cells like B cells have surface bound immunoglobulin (Ig) receptors. Several groups of investigators have subjected lymphocytes to enzymatic radioiodination of their cell surface proteins, followed by disruption of the cell and precipitation by specific anti-immunoglobulin antisera. Using this method, Marchalonis *et al.* (*Transplant. Rev.*, 14, 1; 1973) claim to have detected and isolated significant quantities of surface Ig on T cells and on thymocytes. Their conclusion is that T and B cells have similar amounts of surface Ig. Vitetta *et al.* (*Transplant. Rev.*, **14**, 50; 1973), however, using the same method, could only detect minute quantities of membrane associated Ig on thymocytes or peripheral T cells. Furthermore, if such cell suspensions were first treated to eliminate small numbers of contaminating B cells, then the 'pure' T cell suspensions did not subsequently yield any Ig.

Using a similar method, Grey *et al.* (*J. exp. Med.*, **136**,, 1323; 1972) could not detect appreciable amounts of T cell Ig. Similarly, Lisowska-Bernstein *et al.* (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2879; 1973) were unable to detect T cell Ig on thymocyte or cortisone-resistant thymocyte cell suspensions which had been pretreated so as to kill any contaminating B cells or IgM-containing plasma cells. Antigen-activated T cells were found by labelling experiments with radioactive leucine and methionine apparently to synthesise μ and light Ig chains, but again, this was probably due to contamination by IgM-containing plasma cells. The conclusion is that most if not all T cell Ig is adsorbed material, a conclusion made more plausible by the recent demonstration that activated T cells have Fc receptors which can recognise certain Ig molecules by means of their Fc portion and bind them readily when they are complexed to specific antigen (Yoshida and Andersson, *Scand. J. Immum.*, **1**, 401; 1972). Thus, of four laboratories, using very similar or identical techniques, three maintain that little or no Ig is made by T cells, and only a little more is sometimes displayed on the cell surface.

By contrast, Roelants, Rydén, Hägg and Loor (*Nature*, **247**, 106; 1974) conclude not only that T cells have antigen-specific Ig receptors, but that they are also actively synthesised by the cells carrying them. The system used by Roelants *et al.* to demonstrate T cell antigen-specific Ig receptors is indirect, involving inhibition af antigen binding between T cells and highly radioactive antigen (which is visualised and quantitated by radioautography) after pretreatment of the cells with a polyvalent rabbit anti-mouse Ig serum.

The anatomic origin of the antigen binding cells was determined by Roelants *et al.* by immunofluorescent techniques involving anti-θ serum as a T cell marker, or anti-Ig serum, as a B cell marker (T cells evidently have too few surface Ig molecules to be readily visualised by this second technique). Using this combined immunofluorescent-radioautographic technique, Roelants *et al.* demonstrated a small number of antigen-binding T cells to a synthetic antigen, which in turn could be inhibited by an anti-immunoglobulin serum, thus confirming previous observations (Roelants *et al.*, *J. exp. Med.*, **137**, 1060; 1973). But equally important, the authors go on to conclude that these surface Ig molecules are endogenously produced by the T cells themselves, and are not passively absorbed. The authors reasoned that if Ig molecules are passively absorbed, then after inducing their capping and internalisation by anti-immunoglobulin serum, the T cells should remain negative for cell surface Ig when incubated *in vitro* at 37°C. On the other hand, if endogenous synthesis of the Ig moieties is the rule, it should be possible to demonstrate the reappearance—and therefore 'recapping'—of the receptors. This second situation proved to be the case, and authors conclude their experiments demonstrate active synthesis of Ig receptors for antigen by T lymphocytes.

It should be pointed out that the validity of the interpretation is dependent on independent movement of cell surface components under the influence of capping stimuli. For example, it could be argued that T cell receptors which are intimately associated with passively-acquired surface Ig molecules could be 'co-capped' with the Ig molecules by the anti-Ig treatment. Roelants *et al.* say there is no such precedent for co-capping, but recently Schlesinger has cited unpublished observations from his laboratory indicating that H-2 antigens and C3 receptors on the cell surface of peritoneal macrophages can be co-capped (*Biomedicine*, **18**, 473; 1973).

It is difficult to reconcile the conflicting opinions which presently exist with regard to Ig receptor molecules on T cells. Fairly broad agreement is evolving that T cells do have surface Ig, but much less than B cells have; but whether these few molecules are passively acquired or are endogenously produced, now seems to be the centre of the controversy. Some of the experimental differences may eventually turn out to be related to the use of heterologous anti-immunoglobulin sera which all these experiments entail; although presumed to be 'monospecific', it is doubtful, even after rigorous absorption, whether such sera exist. A second factor which will have to be reckoned with is the part Fc receptors on certain types of T cells may be playing in the various experimental protocols. Basten *et al.* (*J. exp. Med.*, **135**, 610; 1972) have already cautioned others on the difficulties such receptors could cause in interpreting results of studies on antigen binding properties of B cells: this warning must now be extended to similar T-cell studies.

Growing hepatitis B virus

from our Medical Virology Correspondent

THE frustrating problem of propagating the elusive hepatitis viruses in tissue culture has been a major obstacle to defining the biophysical, biochemical and biological properties of these infectious agents and to the production of suitable vaccines. Hepatitis B antigen (Australia antigen), now generally believed to represent the outer protein coat of the virion, provides a convenient specific marker of infection with type B hepatitis virus. The availability of such a marker permitted some progress in tissue culture studies. Brighton and colleagues (*Nature new Biol.*, **232**, 57; 1971) for example, reported the induction of progressive non-cytocidal involvement of normal cellular components of monolayer cultures of human embryo liver cells after inoculation with a well-documented infective hepatitis B serum. Hepatitis B antigen was localised by immunofluorescence in the cytoplasm and in the nuclei of the cells. Smith and Francis (*Cancer Res.*, **32**, 1713; 1972) obtained similar results.

In subsequent studies, following the inoculation of supernatant fluid which had been passaged twice in culture, the outer coat (hepatitis B) antigen was demonstrated by immunofluorescence, using specific animal antiserum, in the cytoplasm of cultured liver cells. Only nuclear fluorescence was observed when human antibody was used (Zuckerman and Earl, *Vox Sang. Suppl.*, **24**, 123; 1973). Similar fluorescent changes were also noted by Coyne and her associates (*Proc. Soc. exp. Biol. Med.*, **138**, 1051; 1971 and London *et al.*, *Can. med. Ass. J.*, **106**, 480; 1972) in liver cells cultured from biopsies obtained from two patients with circulating hepatitis B antigen. In addition the antigen was detected by radioimmunoprecipitation in the supernatant fluid of a few cultures which had been serially passaged.

The morphological and functional capacity of cells maintained in organ culture offers a system for cultivating viruses which simulates conditions in the intact host. Such techniques have proved valuable for cultivating viruses which are difficult to grow in conventional cell monolayers. Cultured fragments of human inguinal lymph nodes were incubated by Jenson and colleagues (*Exp. molec. Path.*, **13**, 217; 1970) with serum containing hepatitis B antigen from a drug addict admitted to hospital with hepatitis. On the basis of serological tests and electron microscopy of the supernatant fluid and examination of ultrathin sections of the explants, it was concluded that some lymph node organ cultures may support the *in vitro* production of hepatitis B antigen. More recently, Zuckerman and associates (*Nature*, **236**, 78; 1972) reported that hepatitis B antigen may be produced in human embryonic liver organ cultures. A progressive increase in the titre of hepatitis B antigen, measured by several techniques and confirmed by immune electron microscopy, was shown with a limited number of sera, but only one successful passage of harvested material was accomplished.

Shikata (*Jap. J. exp. Med.*, **43**, 231; 1973) demonstrated hepatitis B antigen by immunofluorescence for 4 weeks in organ cultures of human foetal liver tissue grown in a Rose chamber. Specific fluorescence was also found in the cytoplasm of spindle-shaped cells growing out from the original liver tissue and it was considered that these fibroblast-like cells phagocytosed the antigen produced by the hepatocytes. The culture medium was not examined and serial passage was not attempted. Taylor and Kelen (*Proc. Can. Fed. Biol. Soc.*, **15**, Abst. 499; 1972) used liver organ and monolayer cultures from recently killed nonhuman primates. Fluid harvested 8 days after primary inoculation of Rhesus monkey liver organ culture with serum containing hepatitis B antigen was found to contain readily detectable antigen as well as a substantial increase in the proportion of the 42 nm (Dane) particles. Passage of harvested fluid was not achieved.

More exotic studies were lately described by Banatvala and Payne (*Lancet*, i, 1359; 1973), who found that sera from patients with hepatitis B infection and sera from some carriers of the antigen induced necrotic changes in the leaves of tobacco plants. Neutralisation tests and preheating the inoculated sera in a boiling water-bath inhibited the necrotic effects in the plants. But again transmission of the virus was not demonstrated.

Although many of these reports are encouraging and suggest that hepatitis B virus may be cultured with difficulty in mammalian cells, consistent serial passage of this virus had not been attained. Panouse-Perrin and her colleagues now report (*Biomed. Express*, **19**, 442; 1973) preliminary results of the cultivation of hepatitis B virus in a human diploid cell line derived from liver biopsies obtained from antigen-negative children undergoing surgery. Electron microscopy revealed the presence of 20 nm icosahedral particles with ninety-two capsomeres in the cell and in the supernatant fluid of the cultures after serial passage. After the fourth passage numerous clusters of capsids, empty icosahedrons about 20 nm in diameter, and electron dense particles measuring 25 to 27 nm were present. These particles are considered to be similar, if not identical, to the internal component or inner core of the 42 nm (Dane) particle (Almeida *et al.*, *Lancet*, ii, 1225; 1971). After fourteen passages cellular degeneration occurred and particles similar to the three morphological entities generally associated with hepatitis B antigen were visualised.

Serological tests, including radioimmunoassay, on supernatant fluid obtained after ultrasonic disintegration of the cultures proved negative for hepatitis B antigen; but precipitin lines were obtained by counter-immunoelectrophoresis when the fluids were tested against sera from patients in the early phase of convalescence from hepatitis B infection. The precipitin lines may have resulted from the interaction between the inner core antigen produced in the cultures and the antibody in serum of patients recovering from hepatitis (Almeida *et al.*, *loc cit*; and Hofnagle *et al.*, *Lancet*, ii, 869; 1973). If these observations can be confirmed and extended then a giant leap forward in hepatitis research has just taken place.

Genetic variation of histones

from our Molecular Genetics Correspondent

ONE of the most interesting observations to have been made in cell biology during the past couple of years is the conservation of amino acid sequences which seems to prevail among the histone proteins. Although only a small number of histones has been sequenced at present, one of the five fractions has an almost identical sequence in several species related only distantly in evolution; its extent of sequence conservation, in fact, seems to be the highest yet observed in any protein. Electrophoretic analysis of histone fractions suggests that conservation of the other four fractions may also be appreciable, although not as extensive as that of histone IV. The apparent homogeneity of sequence in each histone fraction has important consequences for the structure of the chromosomes and, a less fortunate consequence, means that investigations relying upon genetic variation may be rather difficult. In the November issue of the *Proceedings of the National Academy of Sciences*, however, Stout and Phillips (**70**, 3043; 1973) report the existence fo genetic variations in the lysine rich histone fraction I of maize (*Zea mays*).

The lysine rich group of histones is the only one of the five histone fractions that shows any internal variation; it seems to consist of several proteins whose sequences are identical in most of their length but vary at what are probably the amino acid residues present at only a small number of positions. Stout and Phillips have now shown that there may be a genetic polymorphism in these subfractions, with different groups of alleles coding for the lysine rich histones in different inbred lines of maize.

Slight differences in the electrophoretic mobilities of the subfractions of the lysine rich histones were first noticed when a line of maize carrying the *sticky* mutation—which produces sticky chromosomes at meiotic anaphase in pollen cells—was compared with another line lacking the mutation. The rationale for these experiments was that the *sticky* mutation might have as its molecular effect the alteration of properties of one of the chromosomal proteins. In genetic mapping experiments, the variation in one lysine rich histine subfraction (Ia) behaved as though coded by a single Mendelian-segregating gene, independent of the *sticky* locus. Another lysine rich subfraction showing genetic variation (Ic) seems to segregate independently of the locus controlling Ia variation.

In spite of the initial rationale for these experiments, the meiotic mutant *sticky*, and also another meiotic mutant *elongate*, do not seem to control a histone protein. But a comparison of several inbred maize lines showed that each exhibits a specific variation in its histone I subfraction pattern, consistent with earlier experiments which have shown that this fraction is the least conserved in evolution. The only other histone fraction which has been shown to comprise genetic variation is the unique fraction V, which replaces the lysine rich fraction I in avian erythrocytes. Greenaway and Murray (*Nature new Biol.*, **229**, 233; 1971) found that it has two subfractions under genetic control, one with a glutamine at position 15 and one with an arginine. These experiments however, did not show whether the segregating locus comprises only a single gene, as is the case in maize.

The demonstration that variation in lysine rich subfractions in maize may be due to single unlinked mendelian factors contrasts with conclusions derived from hybridisation with DNA of the messenger RNA fraction coding for the histones; these biochemical experiments have suggested that many genes—which in *Drosophila* may be clustered together—might code for each histone protein. But, of course, until the different histone I variations of maize have been sequenced, it is not possible to be certain that the gene controlling their segregation is the structural locus; although the lysine rich histones in general do not seem to suffer modification, until proved otherwise it remains possible that the segregating locus controls modification rather than synthesis *per se*.

The homogeneity of each histone fraction is most consistent with models which suppose that each protein is controlled by a single genetic locus. Although, of course, it is possible to construct models for the organisation of the genome which reconcile unifactorial genetic inheritance with gene multiplication, experiments with messenger RNAs purified for other gene products suggest that the presence in the genome of a single structural gene for each protein may be the more general phenomenon. The histone system at present poses more problems than it resolves, for the striking conservation of histone sequences in disparate organisms remains inexplicable; clearly, the whole sequence of (at least) histone IV is critical for the organism, variation of even a single amino acid being prohibited, which implies that there may be important similarities in chromosome structure in all eukaryotes. But although it is obvious that conservation of histone structures conveys an important message about the organisation of the genetic apparatus, the nature of this message remains elusive.

Diapause regulation by juvenile hormone

from our Insect Physiology Correspondent

When the hormonal control of moulting and metamorphosis in insects was defined about forty years ago it was suggested that the periodic arrest of growth, or reproduction, that occurs in many insect species and which is called 'diapause', was the result of an arrest of hormone secretion—since a state closely resembling natural diapause could be induced by the experimental exclusion of the growth hormones. Experiments on a wide range of insects have largely substantiated this idea. Sometimes it is the neurosecretory cells in the brain which are inactive; sometimes the prothoracic glands. In adult insects the failure of egg development during diapause results sometimes from a failure in the secretion of the juvenile hormone by the corpora allata, as in the potato beetle *Leptinotarsa*; sometimes from an arrest in the neurosecretory cells of the brain, as in overwintering mosquitoes.

But in this story the juvenile hormone has come to occupy a somewhat equivocal role. It was noted by the Japanese workers Fukaya and Mitsuhashi that in the caterpillar of the rice stem borer *Chilo*, exclusion of the corpus allatum induced the diapausing insects to resume their development. These authors therefore inferred that the juvenile hormone was acting as a 'diapause factor'.

Yin and Chippendale (*J. Insect Physiol.*, 19, 2403; 1973) have now reinvestigated this problem in another caterpillar, the southwestern corn borer *Diatraea*. It has been known for some years that in certain Lepidoptera the juvenile hormone experimentally applied may serve as a stimulus to the prothoracic gland to induce secretion of ecdysone and thus to bring about moulting in caterpillars deprived of the brain. This happens in *Diatraea*; and when sufficient juvenile hormone is present the insect undergoes a 'stationary moult', that is, it retains its larval form. Whereas, if only a very small amount of juvenile hormone is present the caterpillar changes to a pupa when it moults.

It has long been known that in Lepidoptera and other insects with a complete metamorphosis a high titre of juvenile hormone causes retention of larval characters, a lower titre signals the evocation of pupal characters, and in the absence of juvenile hormone adult characters appear. Yin and Chippendale produce good experimental evidence to support their novel hypothesis that the diapause state in this particular insect, *Diatraea*, is evoked by yet another defined level of the juvenile hormone titre, slightly lower than that required for a larval-larval ecdysis. In some of the diapause larvae the juvenile hormone titre is apparently high enough to activate the prothoracic gland and thus to promote stationary ecdyses from time to time.

Liquid crystals at Bangalore

from a Correspondent

To commemorate the twenty-fifth anniversary of the founding of the Raman Institute at Bangalore in India and to highlight the present role of the institute as a centre for liquid crystal research, Professor S. Chandrasekhar organised an international conference on liquid crystals from December 3 to 8. The conference was preceded by a week's winter school on liquid crystals led by four guest speakers—P. G. de Gennes (Collège de France, Paris), G. W. Gray (University of Hull) and G. H. Brown and A. Saupe (Liquid Crystal Institute, Kent State University, Ohio).

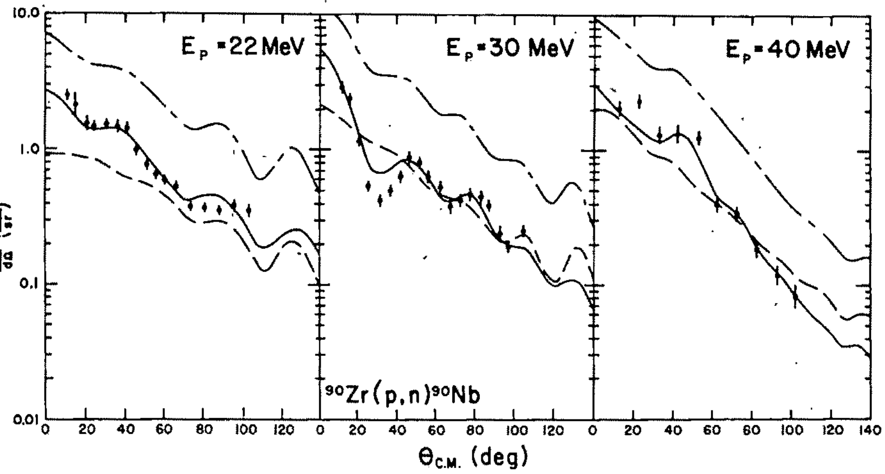
P. G. de Gennes opened the meeting by reviewing developments in the mixed elastic behaviour of smectics A phases. He dealt with continuous deformations, singular lines and dynamical aspects of smectic A to nematic transitions. This contribution and that by G. Durand (Orsay Liquid Crystal Group) on Rayleigh scattering in smectic and nematic materials reflected the high degree of interest in smectic phases and their polymorphism. A. de Vries (Kent State University) in his paper on X-ray studies of thermotropic liquid crystals then expounded his classification of smectic polymorphs based on X-ray diffraction patterns. This system of classification obviously does not satisfy everybody, and it is clear that there is not yet adequate structural information about the eight smectic polymorphs, for the existence of which experimental evidence has been proposed, to form the basis of a thoroughly satisfactory classification scheme. As yet uncategorised smectics probably exist, for example, the smectic phase of 4'-n-octyl-4-cyanobiphenyl described by Gray.

Areas of research which may contribute to solving the problems of smectic polymorphism are those concerned with elucidating molecular motion and diffusion in mesophases. Such investigations featured in presentations by B. J. Bulkin (Hunter College of the City University of New York) on infrared optical activity as a probe of nematic order, by J. M. Schnur (Naval Research Laboratory, Washington) on Raman spectroscopy of nematic and smectic mesophases, by R. Blinc (University of Ljubljana) on soft modes in nematic and smectic liquid crystals and by J. A. Janik (Institute of Nuclear Physics, Cracow) on estimations of rotational correlation times for nematic phases.

Several contributions were made by Chandrasekhar's liquid crystal group at Bangalore, and the following titles reflect the range of physical studies being made at this centre: determination of twist elastic constants of nematic liquid crystals; pressure induced mesomorphism; theory of reflection and transmission by cholesteric films; anomalous transmission in absorbing cholesteric liquid crystals; circular dichroism in absorbing mixtures of right and left handed cholesterics; role of permanent dipoles in nematic order; statistical thermodynamics of the nematic liquid crystal surface; new types of electrohydrodynamic flow patterns in nematic liquid crystals and nuclear magnetic resonance spectra of molecules oriented in thermotropic and lyotropic nematics. Several of these contributions represented joint investigations with the National Aeronautical Laboratory, Bangalore or the Bhabba Atomic Energy Centre, Bombay.

Other presentations of importance were given by Saupe on electrohydrodynamic instabilities—a valuable review illustrated by striking photomicrographs—by D. Demus (Martin Luther Universität, Halle) on calorimetric investigations of liquid crystals, by F. M. Leslie (University of Strathclyde) on a theoretical analysis of distorted twisted orientation patterns in nematics and by E. J. Ambrose (Chester Beatty Research Institute, London) on the liquid crystalline properties of biological microfilaments.

Present interest in liquid crystals for electro-optical displays was reflected in the contributions by J. Billard (Collège de France and Université de Lille), who illustrated how eutectic compositions can be calculated for mixtures of mesogens, and by Gray who described further developments relating to the colourless, stable, room temperature smectics, nematics and cholesterics provided by 4′-n-alkyl- and 4′-n-alkoxy-4-cyanobiphenyls. Such compounds and their mixture (including those incorporating *p*-terphenyl analogues) provide excellent materials for twisted nematics and cholesteric-nematic phase change displays. S. Kobayashi (Saitama Institute of Physical and Chemical Research, Japan) also discussed off-90° twisted nematic films for use as voltage dependent colour controlled devices and orthogonal twisted nematic films, with coloured polarisers, for producing a range of coloured displays.



Differential cross sections for the (p,n) reactions to the isobaric analogue states compared with calculations with the one-step process only (—·—), the two-step process only (- - -) and the one-step and two-step processes combined (——).

Two-step nuclear reactions

from our Nuclear Theory Correspondent

THERE has recently developed a growing awareness of the importance of multistep processes in nuclear reactions. These are of two types: reactions involving pre-excitation of the target nucleus or post-excitation of the residual nucleus by inelastic scattering and reactions involving sequential transfer. If the direct process is inhibited in any way, the multistep processes can account for a significant fraction of the measured cross section, so that any conclusions concerning the structure of the participating nuclei based on the assumption that only the direct one-step process contributes may be gravely in error. Among the many possible multistep processes the two-step ones are the easiest to calculate, and detailed theories have now been programmed for electronic computation.

A relatively simple example of the importance of including two-step processes is provided by the (p,n) reaction to the isobaric analogue state of the target nucleus. This final state has essentially the same structure as the ground state of the target apart from a reversed isospin vector for one of the target nucleons: a neutron is replaced by a proton in the same shell-model state. On a simple view the reaction thus proceeds entirely by the isospin term in the nucleon-nucleus optical potential. The total wave function is thus expressible as a sum of the wavefunction in the elastic channel and that in the (p,n) or quasi-elastic channel. Use of the Schrödinger equation with an isospin-dependent potential that can cause transitions from the elastic to the quasi-elastic channel gives a pair of coupled differential equations (called the Lane equations) for the two wave functions. These can be solved to give the observable cross sections in terms of the parameters of the potentials used. It is then possible by comparing calculations with the experimental data to obtain the best values of the parameters of the potential, in particular of the isospin term. Such analyses have been moderately successful in that with suitable choice of parameters it is possible to fit the data fairly well, and to obtain an estimate of the isospin potential.

These analyses assume that the reaction is a direct one-step process from the incident to the final state. It is, however, possible that the reaction can take place in two or more stages, and this can be investigated using a microscopic model of the interaction in which the contributions of all nucleons outside closed shells are explicitly included.

This model has recently been used by Rickertsen and Kunz (*Phys. Lett.*, **47B**, 11; 1973) to study the contribution to the quasi-elastic cross section due to successive particle transfer: instead of direct (p,n), there is a (p,d) pickup followed by (d,n) stripping, leading to the same final state as before. The formalism for this process is much more complicated than for the one-step process, but it has been worked out to give a set of coupled differential equations that can be solved on a computer.

In these microscopic interactions the essential parameters are those of the effective nucleon-nucleon interaction, expressed as a sum of central and isospin terms, together with those of the potentials describing the distortion of the incident and outgoing waves and the shell model used for the initial and final nuclei.

Rickertsen and Kunz have made a series of analyses of (p,n) quasi-elastic cross sections using both the one-step process on its own and then the one-step with the addition of the two-step. It was found, as shown in the figure, that the one-step alone is not always very successful, even if the absolute magnitude is adjusted by altering the strength of the isospin term but that with the addition of the two-step process the agreement is very satisfactory. It is notable that the one-step contribution on its own gives a cross section greater than that observed, so there is considerable destructive interference when the two-step process is included as well.

It is also found that the strength of the isospin term in the effective nucleon-nucleon interaction varies over a wide range from about 15 MeV to 33 MeV if the data are analysed with the one-step process alone, whereas if the two-step process is included the values of the strength cluster much more closely around a mean value of about 29 MeV. The contributions of the two-step process differ from nucleus to nucleus depending on their individual shell structure and they are such as to account for the data, when combined with the one-step process, with parameter values having a more uniform behaviour from nucleus to nucleus.

Thus both the angular distributions and the absolute magnitudes of the (p,n) quasi-elastic cross sections are much better accounted for by the inclusion of the two-step process. It is physically very plausible and gives a more coherent account of the experimental data. The contribution of a two-step process involving pre- or post-excitation of the target or residual nucleus by inelastic scattering was also calculated and found to be quite small.

The possibility of such two-step contributions to nuclear reactions must therefore be carefully considered, and a full calculation made if one is to obtain a detailed and accurate account of the data.

Upper mantle model variations

from our Geomagnetism Correspondent

As the newly-formed oceanic lithosphere spreads away from its ridge source it gradually cools and contracts; and the elevated, rugged topography characteristic of the ridge ultimately gives way to the lower, smoother surface beneath the sediments of the ocean basin. If the cooling, contracting lithosphere were to move over a laterally uniform asthenosphere, the only other factor governing the ridge shape and dimensions would be the spreading rate. Thus several workers, beginning with McKenzie (*J. geophys. Res.*, **72**, 6261; 1967), have constructed thermal models involving the structure of the lithosphere across ocean ridges in which particular attention has been paid to the effect of spreading rate on the topographic profile. In all such models the spreading rate was found to affect principally the horizontal scale of the topography, with an increase in spreading rate producing a lengthened section but almost no variation in vertical dimensions. But as Haigh (*Geophys. J.*, **33**, 405; 1973) has now pointed out with reference to the North Atlantic, although the differences in horizontal scale predicted by previous thermal models exist, there are also variations of ridge and basin structure with latitude which cannot be attributed to differences in spreading rate. He thus concludes that the basic premise of a uniform asthenosphere is wrong, and that instead the temperature at a given depth in the asthenosphere must vary laterally.

The latitudinal variations which require explanation have been known in general terms for some time, the particular data now analysed by Haigh being derived from Atlantic bathymetric and gravimetric profiles obtained as long ago as 1964–1965. From these it is clear, for example, that between low latitudes and Iceland the depth at which the topographic profiles across the Atlantic ridge system become level in the ocean basins decreases northwards from 5.5 km at 30°N to 3.0 km and 60°N. Because the ocean basin level is not reached at the same distance from the ridge throughout the whole latitude range, there may be a suspicion that the variation of basin depth with latitude arises from differences in lithospheric age. No such explanation is possible here, however, because all the ages involved are greater than 60 million years; and as Sclater *et al.* (*J. geophys. Res.*, **76**, 7888; 1971) have shown, changes in elevation beyond this age are negligible. Nor can the marked northward decrease in basin to ridge crest elevation between the Azores and Iceland (the region studied in detail by Haigh) be explained away quite so simply. On the other hand, spreading effects are significant when it comes to ridge cross-sectional area. Even so, when the effects of variable spreading rate on horizontal scale are adjusted throughout to the spreading rate at 43°N, there is still found to be a marked decrease in ridge cross-section area northwards from the Azores.

To investigate the causes of these variations Haigh has constructed a model in which, in common with previous thermal models, the lithosphere is regarded as a slab of uniform thickness resting isostatically on an asthenosphere assumed to be at constant temperature across the ridge. As new material at this temperature is added gradually to one end of the slab, the slab increases in length so that a point on the lithosphere moves away from the hot edge at a rate governed by the rate at which new material is added. Solution of the relevant differential equations in conjunction with assumed values of the physical parameters involved then gives the temperature distribution in the lithospheric slab for any given slab thickness and composition. But in order to obtain an elevation profile from the temperature distribution it is necessary to know the density of the lithospheric material at the appropriate temperatures and pressures—and this involves all the usual problems in dealing with a body whose composition is unobtainable by direct sampling.

Haigh's approach has been to asssume that the upper mantle comprises basalt and dunite, with or without water, and either in the ratio 1:3 as suggested by Ringwood (*J. geophys. Res.*, **67**, 857; 1962) in his 'pyrolite' model or in the ratio 1:1 as proposed by Press (*Science, N.Y.*, **165**, 174; 1969). The end result is then a series of calculated ocean ridge profiles (elevation-distance graphs out to 900 km form the ridge) for the two different basalt-dunite compositions, with or without the involvement of water, and for various lithospheric thicknesses. In addition, to account for possible heat transfer by radiation, a futher variable in the form of a conductivity increase above 800°C has been introduced.

The general conclusion derived from a comparison of the calculated and observed profiles was that many models give too great a ridge elevation unless the allowed ranges of lithospheric thickness and composition are limited. More specifically, a composition involving a basalt-dunite ratio of 1:3 was found to be more likely than one with a ratio of 1:1; and the mantle must contain a small amount of water in order to allow the decoupling between the lithosphere and asthenosphere to occur at a lower temperature than is necessary for a dry model. In addition, models involving a conductivity increase above 800°C were in poor agreement with observation, having too much elevation at the ridge axis and not enough on the flanks. And, finally, raised temperatures in the asthenosphere were found to give an upward migration of phase boundaries, resulting in a thinner lithosphere and thus a reduction of ridge cross section and elevation.

In the context of the observed variations with latitude between the Azores and Iceland the last of these conclusions is particularly significant, for it implies an explanation. Haigh's next step was thus to compare the North Atlantic topographic profiles with profiles calculated for a range of lithospheric thicknesses. From a least squares fit between each observed profile and the calculated profiles with different thicknesses, it became clear that the lithosphere thins from 85 km at 43°N to 64 km at 61°N (although these thicknesses increase by about 10 km on average if the presence of sediments is taken into account). In view of the conclusion that a thinned lithosphere is associated with raised temperatures in the asthenosphere, Haigh thus suggests that the temperature at a given depth in the asthenosphere gradually increases northwards from the Azores to Iceland. He is also able to show that such a lateral temperature variation in both the asthenosphere and lithosphere can explain the northward rise of the whole basin and ridge system with respect to sea level, and not just the variation of those parameters such as ridge cross section and elevation which are measured with respect to the ocean basin level.

In thinking about a northward temperature increase towards Iceland it is tempting to see Iceland as the region of maximum temperature and thus as either the site of an uprising mantle plume as suggested by Morgan (*Nature*, **230**, 42; 1971) or of a convective overturn as suggested by Bott (in *Implications of Continental Drift to the Earth Sciences*, Academic Press, 1973). If Iceland really is the temperature focus, the northward variations between the Azores and Iceland should be mirrored by similar variations southward between the Arctic and Iceland. At present there are few data from north of Iceland, and so little can be said about this except that Haigh claims some support for the dimensional increase in the ridge to the north in the work of Johnson and Heezen (*Deep-Sea Res.*, **14**, 755; 1967). For the time being, Haigh is obviously unwilling to be drawn into a detailed argument over mantle plumes, and rests content with the comment that his model is consistent with uniquely higher temperatures beneath Iceland. But he emphasises that his general conclusions, if valid, should be applicable to other ridge systems.

Flux of Gases across the Air-Sea Interface

P. S. Liss & P. G. Slater

School of Environmental Sciences, University of East Anglia, Norwich NOR 88C

This article describes the use of a two-layer model to estimate the flux of various gases across the air-sea interface.

In the study of gas exchange between air and water, the interface between the two phases is often considered as a two-layer (film) system[1,2]. The main body of each fluid is assumed to be well mixed; the main resistance to gas transport coming from the gas and liquid phase interfacial layers, across which the exchanging gases transfer by molecular processes (Fig. 1).

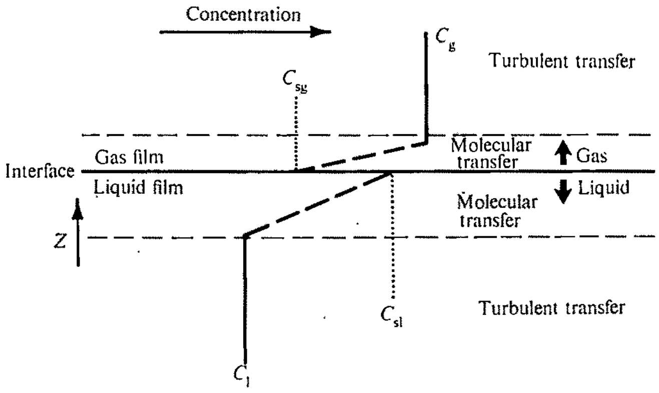


Fig. 1 Two-layer model of a gas–liquid interface.

That this simple model adequately describes processes at the interface must be open to question. The idea of such discontinuities close to the interface is physically unrealistic and, even under given conditions of turbulence in both phases, the layer thicknesses will vary both spatially and temporally. In spite of these difficulties, the film model is useful in visualising processes at the interface and for simplifying theoretical calculations of gas exchange rates. Furthermore, predictions based on the film approach often show little or no difference from those derived using more sophisticated models[2].

Since transport through the layer system is by molecular diffusion, Fick's first law in the one-dimensional form (with z as the vertical direction) is applicable.

$$F = -D\,\partial c/\partial z \tag{1}$$

where F is the flux of gas through layer; D the coefficient of molecular diffusion of gas in layer material; and c the gas concentration.

The more usual form of equation (1) for gas exchange studies is

$$F = k\Delta c \tag{2}$$

where Δc is the concentration difference across the layer (thickness z) and

$$k = D/z \tag{3}$$

k is called the exchange constant and has dimensions of velocity; it is a measure of the flux of gas per unit concentration gradient. The value of k depends on many factors, of which the degree of turbulence in the fluids on both sides of the interface and the chemical reactivity of the gas are among the most important. The reciprocal of the exchange constant is a measure of the 'resistance' to gas transfer, and has dimensions of $[T]$ $[L]^{-1}$. The total resistance to the exchange of any gas will be due to a combination of the resistances of the gas and liquid phases. Any surface contaminants will contribute to the resistance of the phase in which they occur.

Applying equation (2) to the two-layer situation shown in Fig. 1, and assuming that transport of gas across the interface is a steady state process, it follows that

$$F = k_g(c_g - c_{sg}) = k_l(C_{sl} - C_l) \tag{4}$$

where k_g and k_l are the exchange constants for the gas and liquid phases, respectively.

If the exchanging gas obeys Henry's law, then

$$c_{sg} = HC_{sl} \tag{5}$$

where H (the Henry's law constant) = [equilibrium concentration in gas phase (g per cm^3 of air)]/[equilibrium concentration of unionised dissolved gas in liquid phase (g per cm^3 of water)].

Eliminating c_{sg} and C_{sl} between equations (4) and (5),

$$F = (c_g - HC_l)/(1/k_g + H/k_l) = (c_g/H - C_l)/(1/k_l + 1/Hk_g) \tag{6}$$

which can be written as

$$F = K_g(c_g - HC_l) = K_l(c_g/H - C_l) \tag{7}$$

where

$$1/K_g = 1/k_g + H/k_l \tag{8}$$

and

$$1/K_l = 1/k_l + 1/Hk_g \tag{9}$$

Hence, the total resistance (R) expressed on either a gas phase ($1/K_g$) or a liquid phase ($1/K_l$) basis, depends on the exchange constants of the individual phases and the value of the Henry's law constant for the gas concerned.

For convenience in using equation (9), $1/k_l$ may be written as r_l, and $1/Hk_g$ as r_g,

$$R_l = r_l + r_g \tag{10}$$

The numerical values of r_l and r_g for any gas indicate the relative importance of gas and liquid phase resistance for exchange of that particular gas. Except in special cases, it is difficult to measure individual resistances, and most field and laboratory studies have measured only the total resistance. As will be shown, however, for many gases the resistance of one phase tends to predominate. In such cases the total measured resistance is, for all practical purposes, numerically equal to the individual resistance of the rate controlling phase.

Factors Affecting Resistance

Gas phase resistance (r_g). In common with evaporation-condensation of any appreciably pure liquid, the liquid phase resistance should be negligible for water molecules crossing the air–sea interface[3]. This means that for water $r_l = 0$, and exchange of H_2O across the interface will be controlled by processes in the gas phase. In this case the total measured resistance (R) will be numerically the same as the resistance of the gas phase (r_g). Laboratory studies indicate that the value of $k_{g(H_2O)}$ increases linearly with wind velocity[4]. Using the field data of Schooley[5], a mean value for $k_{g(H_2O)}$, applicable to the sea surface, of about 3,000 cm h^{-1}, may be derived. This figure, along with appropriate values for the Henry's law constant, can be substituted into equations such as (8) and (9) in order to split observed values of $K(=1/R_t)$ into their liquid and gas phase components.

Liquid phase resistance (r_l). A number of techniques have been used to determine K_l *in situ* at the sea surface. The results of these experiments have been summarised by Liss[4] and Broecker and Peng[6] and a mean value of $K_l = 20$ cm h^{-1} seems reasonable.

For O_2, $H \sim 30$, $k_{g(O_2)} \sim k_{g(H_2O)} = 3{,}000$ cm h^{-1}. Substituting these, and a value for $K_{l(O_2)}$ of 20 cm h^{-1} into equation (9), shows that $r_l \gg r_g$ and so $k_{l(O_2)} = 20$ cm h^{-1}, that is, for O_2 all resistance to transfer across the interface occurs in the liquid phase. The same is true for all sparingly soluble gases which are not chemically reactive, for example N_2, and the noble gases.

In the case of a chemically reactive gas, transport across the liquid film may be more complex than by straightforward molecular diffusion. For example, with CO_2 as well as the usual concentration gradient for gas molecules in physical solution, at a suitable pH there is also a similar gradient for HCO_3^- and CO_3^{2-} ions. It has been shown in laboratory experiments[4,7] that for $p\text{H} > 5$, and under moderately calm conditions, the ionic species gradient can contribute significantly to the exchange of CO_2 across the interface. Hoover and Berkshire[7] have used a one-layer (liquid) film model to derive the following equation which successfully predicts the exchange enhancements for CO_2 found in laboratory experiments.

$$\alpha = [\tau(\sqrt{(K_0^1 \tau/D)} \cdot z_l)]/[(\tau - 1)(\sqrt{(K_0^1 \tau/D)} \cdot z_l) + \tanh(\sqrt{(K_0^1 \tau/D)} \cdot z_l)] \quad (11)$$

where α is the fractional increase in the exchange constant due to chemical reactivity; τ the ratio of total to ionic forms of inorganic carbon; K_0^1 the hydration rate constant for CO_2 in water; and z_l the thickness of liquid film.

The degree of exchange enhancement for CO_2 depends on the pH (which determines τ), the thickness of the interfacial liquid layer and the hydration rate constant. It has been shown in laboratory experiments that K_l increases approximately as the wind velocity squared[4,8,9], and that enhancement of $K_{l(CO_2)}$ over $K_{l(O_2)}$ can occur at low wind speed[4]. Under more turbulent conditions the thickness of the liquid film decreases to such an extent that re-equilibration of ionic species becomes much less important and is overriden by molecular diffusion. This is the situation at the sea surface, where conditions are generally too rough for enhancement of CO_2 transfer by more than a few per cent[4,7,10]. In the case of gases with larger hydration rate constants, however, such enhancement may become much more important (see SO_2 later).

We have so far attempted to establish that values for the gas and liquid phase exchange constants appropriate to the sea surface are

$$k_{g(H_2O)} = 3{,}000 \text{ cm h}^{-1}; \; k_l = 20 \text{ cm h}^{-1}$$

In order to obtain the k_g value for gases other than water, the value of $k_{g(H_2O)}$ must be multiplied by the ratio of the square roots of the molecular weights of H_2O and the other gas. The value for k_l is based largely on measurements of CO_2 exchange and is probably valid for gases of molecular weight 40 ± 25. For gases outside this range k_l should be multiplied by the ratio of the square roots of the molecular weights of CO_2 and the other gas. For a chemically reactive gas it is probable that k_l may be corrected for chemical enhancement by multiplying it by the value of α derived using equation (11).

In Table 1 values of k_g and k_l, plus a knowledge of H, are used in conjunction with equations (8) and (9) to derive overall exchange constants (K_g or K_l) for each of a number of gases. In subsequent sections this value of K, together with the observed concentration difference of each gas across the air–sea interface, will be substituted into equation (2) to calculate the flux of that gas across the interface.

For all gases considered, other than SO_2, liquid phase resistance controls the exchange ($r_l \gg r_g$). For SO_2 gas phase

Table 1 Calculation of Overall Exchange Constants for a Number of Gases crossing the Air–Sea Interface

Gas	k_g (cm h^{-1})*	α†	k_l (cm h^{-1})‡	H	r_g (h cm^{-1})	r_l (h cm^{-1})	r_g/r_l	K (cm h^{-1})§

* All values corrected for molecular weight.

† All gases, other than SO_2, assumed to be unreactive ($\alpha = 1.0$). α_{SO_2} calculated using equation (11) and τ-1 (at pH 8.0) $= 8.032 \times 10^{-8}$, $K_0^1 = 3.4 \times 10^6$ s^{-1} (ref. 15), $D = 1.8 \times 10^{-5}$ cm^2 s^{-1}, $z_l = D_{(O_2)}/k_{l(O_2)} = 3.96 \times 10^{-3}$ cm.

‡ Values for CCl_4, CCl_3F and MeI corrected for molecular weight.

§ Overall exchange constant, $K = (r_g + r_l)^{-1}$, expressed on either a gas (g) or liquid (l) phase concentration basis.

¶ J. E. Lovelock, personal communication.

resistance is all important ($r_g \gg r_l$). This is in part due to the high solubility of SO_2, but also because of its extremely rapid hydration reaction. A fuller discussion of this point and values of the ratio r_g/r_l at *p*H values other than 8.0 may be found in refs 16 and 17. Exchange of other gases with high solubilities and/or rapid aqueous phase chemistry (for example, NH_3, SO_3 and HCl) is probably also controlled by gas phase resistance.

Flux of Various Gases

Sulphur dioxide (SO_2). In order to substitute the value for $K_{g(SO_2)}$ given in Table 1 (1.6×10^3 cm h^{-1} = 0.44 cm s^{-1}) in equation (2) the mean concentration of SO_2 in oceanic air is required. Junge[18] found values in Hawaii and Florida of 1 and 3 μg m^{-3} respectively. As the measurements were made on the coast and the winds were predominantly from the sea, Junge concludes that these values are fairly representative of marine conditions. Of the measurements made at sea, those for the North Sea[19] are in the range 3 to 9 μg m^{-3}, and for the North Atlantic <1 to 4 μg m^{-3} (ref. 20). These observations seem to point to a value of about 3 μg m^{-3} (3×10^{-12} g cm^{-3}) for the mean SO_2 level in air over the oceans.

Because of the chemical reactivity of SO_2 (rapid hydration and oxidation), it seems reasonable to assume that the SO_2 concentration in oceanic surface waters is zero and that the oceans act as a perfect sink for SO_2.

Substitution in equation (2) gives $F_{(SO_2)} = 4.2 \times 10^{-5}$ g cm^{-2} yr^{-1}. If this flux occurs over the whole area of the oceans (3.6×10^{18} cm^2), the total flux of SO_2 from atmosphere to oceans is 1.5×10^{14} g yr^{-1}. This figure is close to estimates of the total world input of SO_2 to the atmosphere from the burning of fossil fuels (10^{14} g yr^{-1}, ref. 21).

There is good agreement between our value for the air–sea SO_2 flux and the estimates of Eriksson[22] (2×10^{14} g yr^{-1}) and Robinson and Robbins[23] (0.5×10^{14} g yr^{-1}). Our estimate is substantially lower than that of Spedding[24] (9.6×10^{14} g yr^{-1}). This discrepancy arises from Spedding's use of a rather large value for $K_{g(SO_2)}$ (1.4 cm s^{-1}) and an atmospheric SO_2 concentration of 6 μg m^{-3}.

Nitrous oxide (N_2O). Junge and Hahn[25], from measurements in the North Atlantic, found a mean N_2O air concentration of 0.25 p.p.m. (by volume) and an average concentration in the water (expressed on a gas phase basis) of 0.4 p.p.m. This gives a concentration difference of 0.15 p.p.m., which is equivalent to 0.09×10^{-6} cm^3 N_2O per cm^3 of water on a liquid phase concentration basis. Hence the concentration gradient driving the flux of N_2O from the water to the air is 1.8×10^{-10} g cm^{-3}. Substitution of this concentration difference and $K_{l(N_2O)} = 20$ cm h^{-1} in equation (2) gives $F_{(N_2O)} = 3.2 \times 10^5$ g cm^{-2} yr^{-1}. Assuming this flux takes place all over the oceans, the total flux of N_2O from sea to atmosphere is 1.2×10^{14} g yr^{-1}.

This sea to air flux of N_2O may be of very considerable importance in the oceanic nitrogen budget. The amount of fixed nitrogen entering the oceans from river inflow and rain is about 8×10^{13} g yr^{-1}, of which approximately 10% (9×10^{12} g yr^{-1}) is removed to marine sediments in the form of organic nitrogen compounds[26]. The flux of N_2O calculated above is equivalent to 7.6×10^{13} g N yr^{-1}, which is large enough to account for all of the nitrogen inflow to the oceans not removed to the sediments.

Carbon monoxide (CO). From measurements in the Pacific and North Atlantic, Lamontagne *et al.*[27] gives a value of 0.13 p.p.m. for the marine aerial concentration of CO. This is in agreement with estimates by other authors which fall in the range 0.03 to 0.3 p.p.m. Concentrations in the water are subject to diurnal cycling, varying between 2×10^{-8} and 13×10^{-8} cm^3 CO per cm^3 of water[27]. From measurements in the North Atlantic, Seiler (cited in ref. 28) obtains water values in the range 2×10^{-8} to 10×10^{-8}. We will use a mean surface water concentration of 6×10^{-8}. The mean aerial concentration expressed on a liquid phase basis is 2.6×10^{-9} cm^3 CO per cm^3 of water, and so the concentration difference sea–air is 5.7×10^{-8} (that is, surface seawater is twenty-three times supersaturated). This is equivalent to 7.1×10^{-11} g CO cm^{-3}. Substitution in equation (2), along with $K_{l(CO)} = 20$ cm h^{-1}, gives $F_{(CO)} = 1.2 \times 10^{-5}$ g cm^{-2} yr^{-1}. Provided the value used for the mean seawater concentration of CO is applicable to the surface oceans as a whole, the total flux of CO from sea to air is 4.3×10^{13} g yr^{-1}. The magnitude of this calculated flux is about 20% of the amount of CO injected into the atmosphere by human activities (2×10^{14} g yr^{-1}) (ref. 28).

Methane (CH_4). The mean atmospheric concentration of CH_4 over the North Atlantic and North Pacific was found by Lamontagne *et al.*[27] to be 1.4 p.p.m. (by volume). This agrees well with other values found and estimated for the marine atmosphere which fall in the range 1.1 to 1.6 p.p.m. Lamontagne *et al.*[27] measured methane concentrations in surface seawaters at the same time as the air samples were taken, and obtained a mean water value of 4.0×10^{-8} cm^3 CH_4 per cm^3 of water. Expressing the atmospheric CH_4 levels on a liquid phase basis, 1.4 p.p.m. = 3.3×10^{-8} cm^3 CH_4 per cm^3 of water, and comparing this with the mean surface water CH_4 concentration of 4.0×10^{-8}, indicates that the water is only about 20% supersaturated with respect to CH_4 in the air. The concentration difference sea–air is 0.7×10^{-8} cm^3 CH_4 per cm^3 of water (= 5.0×10^{-12} g CH_4 per cm^3 of water). Substitution in equation (2), along with $K_{l(CH_4)} = 20$ cm h^{-1} gives $F_{(CH_4)} = 8.8 \times 10^{-7}$ g cm^{-2} yr^{-1}. If this flux occurs over the whole of the ocean surface, the total flux of CH_4 from sea to air is 3.2×10^{12} g yr^{-1}.

The input of methane from the ocean to the atmosphere is more than an order of magnitude less than the flux of carbon monoxide calculated in the previous section. This arises because of the rather small degree of supersaturation of CH_4 at the ocean surface.

Carbon tetrachloride (CCl_4). Lovelock *et al.*[29] found a mean concentration of CCl_4 in the marine atmosphere over the Atlantic of 71.2×10^{-6} p.p.m. (by volume). Expressed on a liquid phase basis this is 66×10^{-12} cm^3 CCl_4 cm^{-3}. The mean surface water concentration found for samples collected at the same time as the air samples was 60×10^{-12} cm^3 CCl_4 cm^{-3}. Thus the air–sea concentration difference is 6×10^{-12} cm^3 CCl_4 cm^{-3}, which corresponds to 4.1×10^{-14} g CCl_4 cm^{-3}. Substitution in equation (2) along with $K_{l(CCl_4)} = 10.7$ cm h^{-1} gives $F_{(CCl_4)} = 3.9 \times 10^{-9}$ g cm^{-2} yr^{-1}. The total flux of CCl_4 from air to sea is 1.4×10^{10} g yr^{-1}.

The total industrial production of carbon tetrachloride is about 10^{12} g yr^{-1}, of which about 95% is converted to CCl_3F and similar compounds. Hence the maximum amount of CCl_4 which can escape to the air is 5×10^{10} g yr^{-1} (ref. 29). Our calculated total flux of CCl_4 from the atmosphere to the oceans is about 30% of this figure.

Trichlorofluoromethane (Freon-11, CCl_3F). Lovelock *et al.*[29] have found a mean concentration of CCl_3F in the marine atmosphere over the Atlantic of 50×10^{-6} p.p.m. (by volume) or, expressed on a liquid phase basis, 10×10^{-12} cm^3 CCl_3F per cm^3 of water. The mean surface water concentration measured simultaneously was 7.6×10^{-12} cm^3 CCl_3F cm^{-3}. The concentration difference air—water = 2.4×10^{-12} cm^3 CCl_3F cm^{-3} = 1.5×10^{-14} g cm^{-3}. Substitution in equation (2) along with $K_{l\,(CCl_3F)} = 11.3$ cm h^{-1} gives $F_{(CCl_3F)} = 1.5 \times 10^{-9}$ g cm^{-2} yr^{-1}. The air–sea flux of CCl_3F over the whole of the oceans is 5.4×10^9 g yr^{-1}.

United States production of CCl_3F is 0.09×10^{12} g yr^{-1} (ref. 21). From this a total world production of about 0.3×10^{12} g yr^{-1} seems reasonable. As there are no known natural sources for this compound the calculated flux from the atmosphere to the ocean seems to be about 2% of the world production.

Iodomethane (MeI). Lovelock *et al.*[29] found a mean atmospheric concentration of iodomethane over the Atlantic of 1.2×10^{-6} p.p.m. (by volume). Expressed on a liquid phase basis this is 5.0×10^{-12} cm^3 MeI per cm^3 of water. The mean surface water concentration was 135×10^{-12} cm^3 MeI cm^{-3}. Hence the sea–air concentration difference $= 130 \times 10^{-12}$ cm^3 MeI cm$^{-3} = 8.2 \times 10^{-13}$ g MeI cm^{-3}. Substitution in equation (2) along with $K_{1(\mathrm{MeI})} = 10.6$ cm h^{-1} gives $F_{(\mathrm{MeI})} = 7.6 \times 10^{-8}$ g cm^{-2} yr^{-1} and the total flux of MeI from oceans to atmosphere $= 2.7 \times 10^{11}$ g yr^{-1}.

It is well known that the I/Cl ratio in freshwater environments is much higher than the same ratio in seawater. One way to explain this is to assume that there is a preferential transfer of I relative to Cl across the sea–air interface. Miyake and Tsunogai[30] propose evaporation of I_2 molecules from the sea surface as the transfer mechanism. Such an explanation seems doubtful as no one has yet detected I_2 in seawater samples. Further, even if I_2 were found near the interface it would be likely to react with dissolved organic molecules which exist in high concentration at the sea surface[31].

Table 2 Calculated Fluxes of Various Gases crossing the Air–Sea Interface

Gas	SO_2	N_2O	CO	CH_4	CCl_4	CCl_3F	MeI	$(Me)_2S$
Total oceanic flux g yr^{-1}	1.5×10^{14}	1.2×10^{14}	4.3×10^{13}	3.2×10^{12}	1.4×10^{10}	5.4×10^{9}	2.7×10^{11}	7.2×10^{12}
	(−)	(+)	(+)	(+)	(−)	(−)	(+)	(+)

+, Sea→air; −, air→sea.

Miyake and Tsunogai[30] have calculated that in order to balance the iodine cycle on the Earth, 5×10^{11} g I yr^{-1} must cross the sea–air interface. The calculation given above indicates that the flux of iodomethane from the oceans to the atmosphere is about 2.7×10^{11} g yr^{-1}, which is equivalent to 2.4×10^{11} g I yr^{-1}. This is approximately half the total amount of iodine needed to balance the budget for this total amount of iodine needed to balance the budget for this element. In our view iodomethane is a much more likely vehicle than I_2 for the transfer of iodine from the ocean to the atmosphere.

Dimethyl sulphide (DMS, $(Me)_2S$). Lovelock *et al.*[14] have found a mean surface water concentration of DMS in the Atlantic Ocean of 1.2×10^{-11} g cm^{-3}. Dimethyl sulphide was not detectable in the marine atmosphere and has not yet been found in the open air. Taking the atmospheric concentration of DMS to be zero, the concentration difference between the sea and the air is 1.2×10^{-11} g cm^{-3}. Substitution in equation (2) along with $K_{1(\mathrm{DMS})} = 19.2$ cm h^{-1} gives $F_{(\mathrm{DMS})} = 2.0 \times 10^{-6}$ g cm^{-2} yr^{-1} and the total flux of DMS from oceans to atmosphere $= 7.2 \times 10^{12}$ g yr^{-1}.

In order to achieve balance, most budgets for sulphur at the Earth's surface have to invoke a process in which some volatile compound (usually H_2S) is produced over the land surface and/or the oceans. A recent sulphur budget[32] gives a figure of 268×10^6 ton SO_4 yr^{-1} (89×10^{12} g S yr^{-1}) for this flux.

The sea–air flux of dimethyl sulphide calculated above (7.2×10^{12} g yr^{-1}) is equivalent to 3.7×10^{12} g S yr^{-1}. This corresponds to about 4% of the amount needed to balance the sulphur budget. It would seem that if, as suggested by Lovelock *et al.*[14], dimethyl sulphide is the "missing" volatile compound in the sulphur cycle then only a small fraction of it is released over the oceans, and a terrestrial source must be sought for the remainder.

Conclusions

The results of the flux calculations presented here are summarised in Table 2. Obviously the results presented are only as good as the data used in the calculations. There is some uncertainty in choosing mean values for the gas and liquid phase exchange constants. For example it is not at all well known from measurements at the sea surface how k_1 varies with wind speed. Even greater uncertainties arise with the air and water concentrations for some of the gases. Many of these occur at low concentrations and require sophisticated apparatus for their detection. The problem is particularly acute for those gases where the degree of supersaturation is small. As further data become available it will be a relatively simple matter to recalculate the fluxes and to extend the approach to other gases. Although the model developed has been applied in this instance to the air–sea system, it should be possible to use it at any air–water interface in the environment provided the necessary data and field measurements are available.

We thank Drs J. E. Lovelock and C. H. Mortimer for helpful discussions and the Gassiot Committee of The Royal Society for financial assistance.

Temporal Variation of the Seismic Moment Tensor and the Evidence of Precursive Compression for Two Deep Earthquakes

A. M. Dziewonski
Department of Geological Sciences, Harvard University, Cambridge, Massachusetts 02138

F. Gilbert
Institute of Geophysics and Planetary Physics, University of California, San Diego, La Jolla, California 92037

For two deep earthquakes, about 80 *s before the abrupt onset of each, the hypocentral region begins to experience compression.*

In elastodynamic terms, an earthquake is caused by the sudden release of stress in the Earth. The difference in stress, before and after the earthquake, is termed the stress drop, and the volume integral of the stress drop, which has the dimensions of (force × distance), is termed the moment, or moment tensor. (In displaying the results of numerical calculations we shall use the sign convention consistent with the definitions of the tension and compression axes commonly used in seismological literature.)

The body forces, equivalent to the stress drop, are said to constitute the source mechanism of the earthquake. The balanced double-couple system of equivalent forces has been almost universally adopted in studies of the source mechanism of earthquakes; papers by Randall[1], Knopoff and Randall[2] and Randall and Knopoff[3] represent notable exceptions. Representation of the stress drop by such a system involves two assumptions: (i) the stress is deviatoric; and (ii) the effective stress drop along one of the principal axes is equal to zero. If an earthquake should have, for example, a partly isotropic moment tensor, then studies of its source mechanism based upon the *a priori* assumption of a system of double couples must fail to reveal the isotropic part. It is clear that a procedure in which the elements of the moment tensor can be determined directly from the seismic data is preferable to one that imposes *a priori* restrictions.

It is also important that each of the elements of the moment tensor be independently determined as a function of time (or frequency). Such a general approach can be helpful in establishing the sequence of events at the source and provide data for testing the applicability of various dynamical source models.

New analysis technique

The general approach to the source mechanism problem has now become practically feasible because of the development of a novel method of processing the Fourier spectra of observed seismograms. The particular procedure applied here depends on the availability of digitised recordings from a large number of well distributed stations.

The theory of excitation of normal modes by point sources and the principle of retrieving the moment tensor from seismic data have been described by Gilbert[4,5]. A finite duration (as opposed to instantaneous stress release) of a seismic event implies that the moment tensor is a complex function of frequency. We shall assume, however, that the source represents a point in space; possible errors due to this assumption are largely avoided by considering in the analysis only those modes with wavelengths that are approximately one order of magnitude greater than the expected source dimensions.

Because the temporal changes in the stress release pattern are our principal interest, we shall determine in this report the moment rate tensor—$\mathbf{m}(t)$, the time derivative of the moment tensor—$\boldsymbol{m}(t)$: $\mathbf{m}(t) = \mathrm{d}(t\boldsymbol{m})/\mathrm{d}t$. In the frequency domain, the relationship between the spectra of the moment rate tensor—$\mathbf{M}(\omega)$, and moment tensor—$\boldsymbol{M}(\omega)$ is: $\mathbf{M}(\omega) = i\omega\boldsymbol{M}(\omega)$. Consequently, the procedure described below can be used with only minor changes to determine the spectrum of the moment tensor.

Gilbert's result can be generalised for a source of finite duration; the amplitude of the ground motion due to a normal mode at a certain point on the surface of the Earth is a linear function of the elements of the moment rate tensor $m_j(t)$,

$$u(t,\theta,\phi) = \cos\omega_0 t \cdot \exp(-\omega_0 t/2Q) * \sum_{j=1}^{6} a_j m_j(t)$$

where the symbol $*$ denotes convolution and where the coefficients a_j depend on coordinates θ and ϕ of the receiver, the location of the source and the assumed model of the Earth; parameters ω_0 and Q represent the eigenfrequency and the quality factor of a particular mode. The dependence of u on ω_0 and Q is eliminated by calculating the Fourier transform of the equation above and integrating the resulting cosine and sine transforms over the entire frequency range. Having made observations at a large number of well distributed stations we can solve a system of normal equations for the components of $M_j(\omega_0)$, the Fourier transform of $m_j(t)$ at ω_0.

In reality, the observed spectra represent the superposition of a great many modes and the method cannot be applied as described above. But the spectral energy of a mode is strongly concentrated about its eigenfrequency, and it is sufficient to perform the integration in the frequency domain over a relatively narrow frequency interval in order to retrieve nearly all of its energy. This still leaves open the possibility of interference of another well excited mode with an eigenfrequency close to that of the currently analysed one. But, if the receiver coverage is sufficiently dense, the effect of the modes with angular order numbers different from that of the mode of interest is largely eliminated from the final system of normal equations. The elimination would be complete if the coverage were continuous, because of the orthogonality of the spherical harmonics which enter into the coefficients a_j. This is the same principle which enabled Mendiguren[6,7] and Dziewonski and Gilbert[8] to isolate spectral peaks of normal modes which could not be recognised in the spectra of individual recordings.

Application of the method

Because of the integration procedure described above, the success of the method depends to a large extent upon the precise knowledge of the eigenfrequency of each normal mode for which we attempt to determine the moment tensor. Our previous observations of normal modes[8-10] and inversion studies[9,11,12] have been very helpful in this respect.

Because a moment rate tensor can be expected to vary rather slowly with frequency, we have chosen in this study to determine an average moment rate tensor for a number of adjacent and equal frequency intervals by taking into account excitation of all modes with eigenfrequencies within a prescribed interval and wavelengths greater than an assumed minimum.

The principal advantage of the method proposed here is that in studying the source mechanism we can utilise the entire information contained in a seismic recording. Consequently, the moment rate tensor is derived from the energy of modes representing a wide range of phase velocities, wavelengths and various ratios of compressional and shear energies[9,10]. All previous attempts to determine the source mechanism from the observed amplitudes of surface waves or free oscillations were confined to the fundamental modes. There are, of course, practical limitations on the frequency range of the proposed analysis. The magnitude of an earthquake combined with the instrumental response of the recording stations determines the lower frequency limit. The present upper frequency limit (about 0.014 Hz) is imposed only by the extent of the existing theoretical calculations of eigenfrequencies and eigenfunctions of normal modes.

We have applied the theory and method described above to the analysis of the stress release process of two deep South American earthquakes: the Colombian earthquake of July 31, 1970 (1708 : 05.4 GMT, 1.5° S, 72.6° W, $h = 650$ km) and the Peru–Bolivia border earthquake of August 15, 1963 (1725 : 27.9 GMT, 13.8° S, 69.3° W, $h = 543$ km).

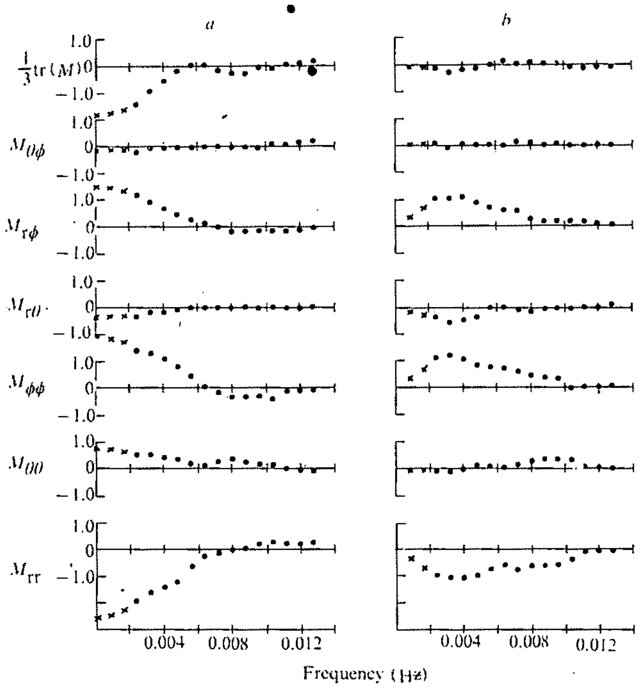

Fig. 1 Moment rate tensor of the Colombian earthquake of July 31, 1970, as a function of frequency. *a*, Real; *b*, imaginary. ●, Values determined from the analysis of excitation of normal modes; ×, extrapolated values. The isotropic component of the moment rate tensor is shown at the top; the remaining diagrams represent the deviatoric part of the moment rate tensor; that is, the isotropic stress rate has been removed for the measured values of the elements M_{rr}, $M_{\theta\theta}$ and $M_{\phi\phi}$. The coordinate system adopted is that of the lower hemisphere with the r axis pointing downwards, θ axis to the north and ϕ axis to the west. To obtain a result in (dyne-cm) the values shown in the figure should be multiplied by a factor of 5×10^{27}.

Figure 1 shows the result of processing 165 recordings of the Colombian earthquake. The centre frequencies of individual intervals were $(1/2\pi)$ .0.005 n Hz ($n = 3, 4, \ldots, 16$) and the half width was $(1/2\pi)$ .0.0025 Hz. The total number of modes considered was 1,348 (only those modes with wavelengths greater than 1,000 km were taken into account) for a total number of observational equations of over 200,000. The number of observational equations for individual frequency intervals was variable but never less than 5,000. Error estimates were obtained from regression analyses but they are too small to be shown in the scale of the figure.

The isotropic stress rate is shown at the top of the figure (negative stress corresponds to compression), and the remaining diagrams represent the elements of the deviatoric part of the moment rate tensor; that is, the isotropic stress rate has been subtracted from the diagonal elements M_{rr}, $M_{\theta\theta}$ and $M_{\phi\phi}$.

If the stress release were instantaneous (a step function in time), the imaginary part of the moment rate tensor should be equal to zero, and the real part should be independent of frequency. This is clearly not the case. If the stress were released uniformly over a period of time from $t = 0$ to $t = t_1$, then the cosine transform should be proportional to sin $\omega t_1/\omega t_1$ and the sine transform to $\sin^2(\omega t_1/2)/(\omega t_1/2)$. With the exception of the isotropic component, this seems to be a relatively good approximation, and the least squares fit yields $t_1 = 78$ s.

The isotropic component shows an entirely different behaviour, with the imaginary component being nearly zero at all frequencies and a significant real component decreasing in frequency more rapidly than all the other elements. This implies a non-zero isotropic stress rate at negative times, or, in other words, a compression preceding the origin time determined from the first arrivals of body waves.

The results of the analysis of 46 digitised recordings of the Peru–Bolivia border earthquake also indicate a release of purely compressional stress at negative times. The elements of the moment-rate tensor for this earthquake are 2.5 times less, on average, than for the Colombian event and the estimate of the uniform radiation time is also lower: $t_1 = 72$ s.

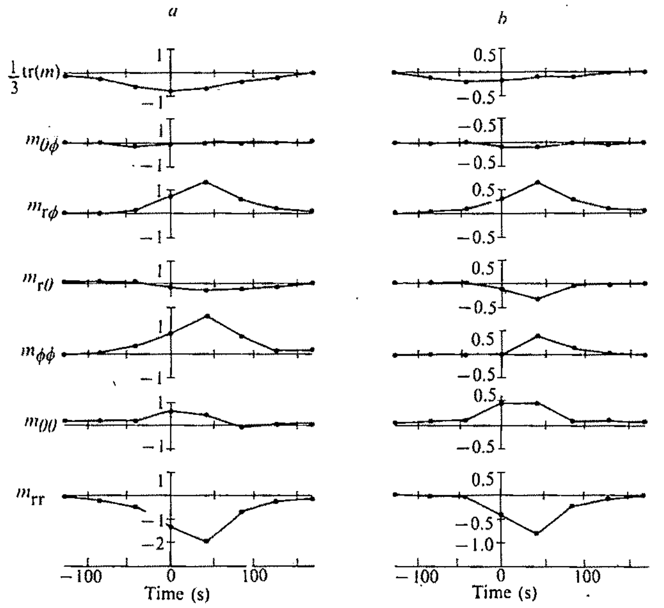

Fig. 2 Moment rate tensors of the Colombian earthquake of July 31, 1970 (*a*) and Peru–Bolivia border earthquake of August 15, 1963 (*b*) as a function of time. Significance of the components of the moment rate tensor is the same as in Fig. 1. To obtain a result in (dyne-cm/sec) the values shown in the figure should be multiplied by a factor of 4×10^{25}.

Our results must be extrapolated for the low frequencies ($n = 0$, 1 and 2) before the frequency domain data can be synthesised into the time domain. Such a procedure is always somewhat arbitrary, but on the basis of theoretical considerations of Aki[13] and the experimental results of Mendiguren[6] for the Colombian earthquake we felt that we were justified in extrapolating the moment rate tensor obtained by the least squares fit of a uniform radiation source. The crosses in Fig. 1 identify values obtained by extrapolation; these values appear to merge smoothly with the experimental data. We believe that the results described later are not materially affected by the uncertainty that might have been introduced by extrapolation.

The time functions of the moment rate tensor are shown in Fig. 2 (it should be remembered that the values shown in the figure do not refer to an instant of time $t = n\Delta t (\Delta t \approx 40$ s) but they represent an average stress release over a period of time from $(n-1)\Delta t$ to $(n+1)\Delta t$). The moment rate tensor decays to a zero value rather rapidly for both positive and negative times, which indicates that the long-period noise is low. The compressional isotropic stress-rate represents a dominating factor at negative times, but there also seems to be a detectable amount of shear stress released during the last 80 s interval before the 'origin time'.

In the next step, we find the principal stress rates and directions of the principal axes of the moment rate tensor for a number of time intervals. The results are shown in Fig. 3, where the axes are numbered according to the decreasing absolute value of the principal stress rate. The directions of the axes are shown only for $t = -40$, 0, 40 and 80 s, because at other times the shear stress rate is comparable to the noise level and the results are incoherent.

The total stress change can be found by integration in time of the results shown in Figs 2 and 3. For example, we have computed the total change in the isotropic stress to be -5.1×10^{27} dyne-cm for the Colombian event and -1.3×10^{27} dyne-cm for the Peru–Bolivia earthquake; using the elastic constants of the model B497[10], we find the decrease of volume to be 1.9 and 0.5 km^3, respectively.

Comparison with other work

Our results are compared with the directions of the compression, tension and null axes found from the fault plane solutions by Mendiguren[6] for the Colombian earthquake and Chandra[14] for the Peru–Bolivia border event.

Our solution is fairly consistent with that of Mendiguren, except for a horizontal rotation of all three axes by approximately 20° and a slow decrease of the plunge of the dominating axis of compression from 79° to 65°.

The differences with the solution of Chandra are much more significant. It seems that his determination of the direction of the tension axis has been in error; it remains at odds with all the other results from this region[15]. Our results show that the azimuth of the tension axis of the average stress released between 0 and 80 s after the origin time is 232°, which is in a good agreement with the trends found from other fault plane solutions by Isacks and Molnar[15]. The most striking result of our analysis of the Peru–Bolivia border earthquake is the significant rotation in time of axes II and III, whereas the position of axis I remains almost unchanged at positive times. This observation indicates that in some cases the pattern of stress release may undergo a significant change during the event.

The validity of a solution for a moment tensor can be confirmed by a theoretical calculation of the excitation of normal modes and comparison of this result with the observed spectra. The method of phase equalising the observed spectra for spectral peaks belonging to individual normal modes represents a severe test of a given source mechanism, since a successful result of this operation depends on the ability to estimate correctly the amplitudes of all the modes within a certain frequency band. We have performed such calculations for the Colombian earthquake data using both the double couple solution of Mendiguren[6] and our results shown in Fig. 1. The results obtained using our solution were generally better than when the double couple model was used. Improvement was especially significant for the modes with a large content of compressional energy and relatively long periods ($T > 200$ s); it can be shown that these modes are particularly sensitive to the isotropic component of a moment tensor. The outcome was also successful when we used our solution for the Peru–Bolivia earthquake, but we have not tested the solution of Chandra. In general, the results of the test confirm the consistency of our moment tensors with the observations.

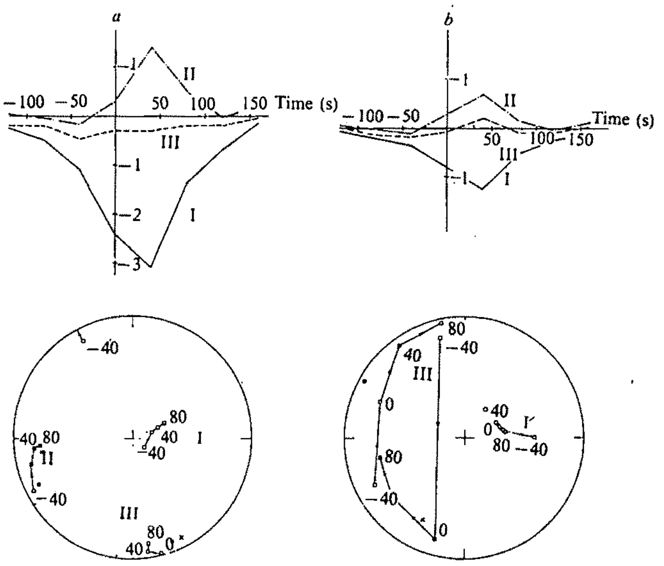

Fig. 3 Temporal variations of the principal stress rates and directions of the principal axes of the moment rate tensor (*a* and *b* and the scale conversion factor as Fig. 2). The large circles in the lower part of the figure represent equal area projections of the lower hemisphere of a focal sphere. Results obtained from fault plane solutions by Mendiguren[3] (left) and Chandra[14] (right) are shown for comparison. ☐, Compression and tension axes of moment rate tensor; ○, ●, ×, compression, tension and null axes from fault plane solutions.

Our results show that a hypocentral compression precedes the main phase of both earthquakes analysed here. This effect may be caused by a transition of the matter in the mantle into a denser phase. If such a change is associated with a release of thermal energy, it might provide an increase in temperature which is necessary to initiate a shear-melting instability which has been suggested by Griggs and Baker[16] as a possible cause of deep earthquakes.

The results in Fig. 3 indicate that some shear stress is also released prior to the 'origin time'. The directions of the principal axes of stress rate at negative times are basically consistent with those determined for the main phases of the earthquakes. The statistical significance of this result is less certain than in the case of isotropic stress, because of the difference of magnitude in the deviatoric part of the moment rate tensor before and after the origin time. But if this result is correct it further confirms the theory of Griggs and Baker which predicts the phase of a relatively slow release of shear stress before the occurrence of shear melting.

Further possibilities

Our results for the two earthquakes seem to confirm that, if the data are adequate, fault-plane solutions provide a reasonably good estimate of the directions and signs of the principal axes of a moment tensor. However, the magnitude of the deviatoric stress rate estimated for axis III represents approximately one-fifth of that of axis I and it is statistically significant. This indicates that although the double couple model may represent a convenient approximation, the mechanism named by Knopoff and Randall[2] a 'linear compensated vector-dipole' could possibly play a significant role in the process of stress release at long periods.

It is not justified to extrapolate conclusions made on the basis of observations in one frequency range into an entirely different frequency range. For example, the temporal variations of the release of isotropic stress indicate that it is a long-period phenomenon; the rate of its release does not appear to change at the 'origin time' (Fig. 2). Consequently, one should not expect to observe a significant effect of a volume change on the amplitudes and signs of the first arrivals of body waves. It would be wrong, of course, to infer from the short period data that a change of volume did not take place, yet such inferences have been made in a number of published papers.

The sequence of events at the source observed for the two analysed earthquakes leads us to the following speculation. If the volume change which preceded the release of the short period energy were insufficient to initiate the shear melting instability, then such a 'silent earthquake' would most likely remain unreported. It may be that hypocentral volume changes which are not followed by the release of short period energy occur frequently. Perhaps the largest of those might have generated free oscillations of the Earth that could be detected by very sensitive instruments.

We believe that analyses such as presented here should be applied to recordings of other events from different tectonic regions and different depth ranges. Information on the stress release prior to the main phase of earthquakes may provide important clues with respect to the problem of earthquake prediction.

Our method of studying the source mechanism can be extended to travelling waves and used to study the source properties of smaller events. In particular, determination of the ratio of energies released by the isotropic and deviatoric part of the moment tensor may be useful as a discriminant between natural events and explosions[17].

We thank Mrs Jessie Maniatis for digitising the Colombian data. Dr Anton L. Hales has critically read the manuscript and offered comments. This research was supported by National Science Foundation grants and the Committee on Experimental Geology and Geophysics, Harvard University.

Structural Response of Vertebrate Photoreceptor Membranes to Light

W. T. Mason,* R. S. Fager† & E. W. Abrahamson

Department of Chemistry, Case Western Reserve University, Cleveland, Ohio 44106

A distinct structural response in disk membranes from frog retinal rod outer segments was found directly proportional to exposure to light. Translocation of rhodopsin from the intradisk hydrophilic surface to the internal hydrophobic phase of the membrane was observed.

ABSORPTION spectral changes following illumination of the chromolipoprotein rhodopsin in the stack of laminar disk membranes of vertebrate rod photoreceptor cells have generally been interpreted as conformational changes in the lipoprotein moiety[1–4]. Although optical rotatory dispersion and circular dichroism studies of rhodopsin do not seem to support this idea[5,6], it is difficult to arrive at any other molecular interpretation, particularly in view of the established *p*H changes and the exposure of titratable thiol groups that accompany certain of these intermediate processes[3,4]. The question naturally arises as to whether such suspected molecular changes are reflected on the gross structural level of the membrane itself. A substantial amount of rhodopsin[7] in the photoreceptor disk membrane of the frog coupled with the evidence of light-induced conformational changes in the rhodopsin moiety[1–4] indicate that a membrane structural response to light may occur.

Studies of orientated hydrated pellets of isolated disk membranes by X-ray diffraction[8] indicate that structural changes in the disk membranes do occur upon illumination and a slight movement of rhodopsin in the disk membrane upon light exposure has been detected by Blaisie[9,10]. Furthermore, studies of the thermal broadening of X-ray diffraction maxima and the lipid and fatty acid composition of the membrane[11,12] indicate a fluid-like milieu, which makes possible mobility for the chromophore in the disk photoreceptor membrane. In the light of these indications we have attempted to visualise, in a direct manner, such structural changes that might occur in the photoreceptor membrane upon light exposure.

Here we describe the results of our application of freeze-cleave-etch electron microscopy to study photodynamic responses in intact retina, rod outer segments, and disk membranes of the frog, *Rana catesbiana*. The characteristically weak intermolecular interactions in the hydrophobic portion of the disk membrane and the relatively strong interaction of hydrophilic protein with surrounding cell stroma enable this technique to discriminate among three membrane surfaces: the external hydrophilic surface of the disk, the interior hydrophobic region of the disk bilayer, and the internal hydrophilic disk surface, enclosing an internal aqueous region. By electron microscopy of cleaved, shadowed and etched samples, a distribution of these three surfaces can be seen.

Several preparations of the retina from dark adapted frogs were examined in isotonic Boyle-Conway medium[13], as well as in hypertonic and hypotonic solution. Intact rods were prepared by dissection of whole retina into the Boyle-Conway medium and either flotation of outer segments in 50% buffered sucrose or agitation of the retina and filtration through nylon netting. In addition, pure rods were prepared by density gradient centrifugation and examined. Whole retinae were gently excised and frozen in Freon 22 on stainless steel planchets; these were immediately subjected to a high vacuum (2×10^{-6} torr) at −196° C, in a Denton Co. freeze-etch apparatus. Additional samples were frozen either in the dark or after various stages of light exposure up to 2 min at 25° C. The apparatus containing the planchets was evacuated, the samples cleaved at −197° C and subsequently etched at 95° C for 2 min. The etched samples were then replicated with platinum-carbon, floated on water and taken up on carbon coated copper grids. All electron microscopy was performed with a Hitachi 11-UA instrument.

Membrane surfaces

By this technique we have made many observations on the photoreceptor disk membranes of the frog and have found large differences between dark and illuminated membrane surfaces. In the dark (Fig. 1), all cleaved disk membranes examined showed a smooth outer hydrophilic surface, a particle-free rippled hydrophobic surface and a highly particulated intradisk hydrophilic surface. Identification of these surfaces was made on several bases. First, samples were subjected to etching without previous cleaving. By this technique, it could be assumed that exclusively external disk surfaces were observed. Second, membranes were subjected to light sonication for 10 to 15 s and subsequently etched without previous cleavage. In dark-adapted sonicated samples, only a smooth and particulated surface was observed. The surface bearing particles was similar to the internal hydrophilic surface observed by the cleave-etch technique with dark-adapted membranes. Upon similar sonication treatment of light-adapted samples, only smooth surfaces were observed, implying that translocation of the particles away from the intradisk hydrophilic surface had occurred. Third, a morphologically different surface was evident upon cleavage of the sonicated preparation prior to etching. This surface was the preferred cleavage plane and exhibited a 'rippled' texture. We believe this surface to be the hydrophobic region of the membrane.

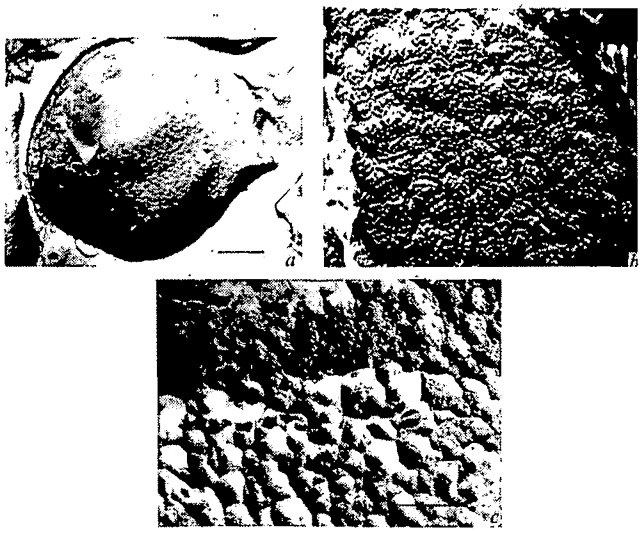

Fig. 1 *a*, Partial surface of dark-adapted photoreceptor disk membrane from preparation of isolated *Rana catesbeiana* rod outer segments; note particle-free outer hydrophilic and rippled hydrophobic surface (bar=0.8 μm). *b*, Partial surface of dark-adapted photoreceptor disk membranes from preparation of isolated *R. catesbeiana* rods; note linear arrays of $\sim$50 to 60 Å particles on intradisk hydrophilic surface (bar=0.18 μm). *c*, Dark-adapted photoreceptor disk membrane fragment from preparation of *R. catesbeiana* rods; note particle-free, rippled hydrophobic region in lower half of figure, and particulated surface immediately above. A smooth membrane area representing an external hydrophilic surface is seen on the upper left hand portion of the figure (bar=0.10 μm). Arrows indicate direction of platinum shadow.

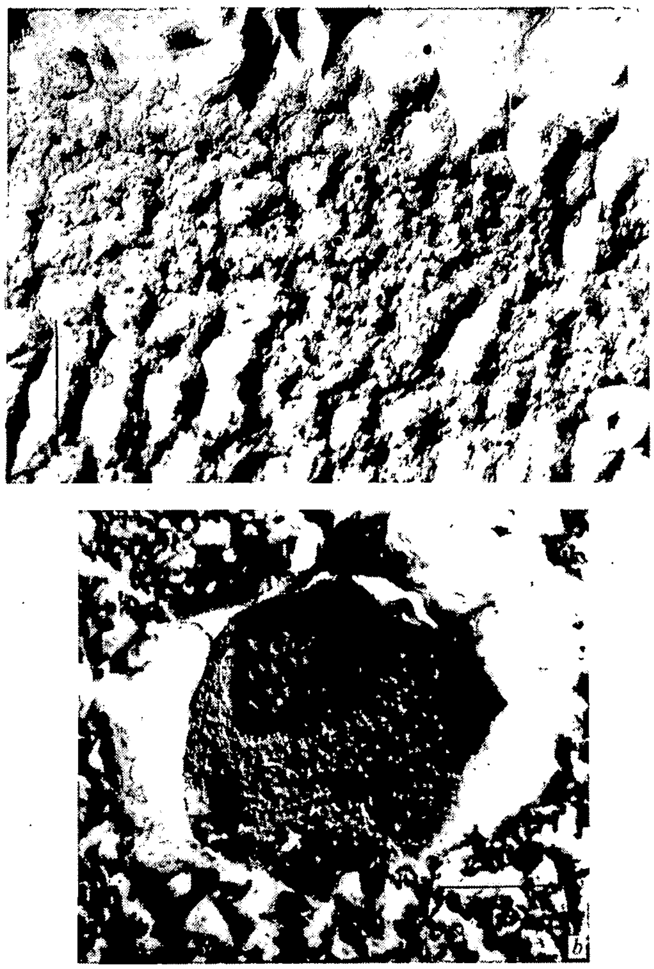

Fig. 2 *a*, Fully bleached disk membrane fragment from preparation of isolated *R. catesbeiana* rods; note particulated hydrophobic surface with $\sim$120–150 Å particles (bar=0.32 μm). *b*, Fully bleached disk membrane fragment from *R. catesbeiana* rods; note particulated hydrophobic surface and adjacent smooth hydrophilic surface (bar=0.12 μm). Arrows indicate direction of platinum shadow.

The particles on the internal hydrophilic surface of the dark-adapted preparations, tentatively identified as rhodopsin, were of the order of 50 Å diameter and seemed to project more than 20 Å beyond the internal hydrophilic membrane surface, although it was difficult to determine the exact height of particles by shadow length in freeze-etched preparations because of random sample tilt in the plane of the incident shadow. Further examination showed the particles to be discrete with a distinct, short-term order relative to other particles, that is, protuberances were arranged in a curvilinear array of ten to twenty discrete particles as seen in Fig. 1*b*. This ordering is not inconsistent with the planar square array reported by Blasie *et al.* on the basis of an optical transform of electron micrographs of isolated disk photoreceptors[14].

After light exposure at room temperature for 2 min at a distance of 4 foot from a standard 150 W bulb to yield predominantly metarhodopsin$_{380}$II in the disk membrane (by spectral monitoring) and quick freezing of the samples, a substantial change in the macroscopic surface structure of the disk membrane was observed (Fig. 2). Once again, a smooth outer hydrophilic surface was apparent. This surface was clearly identified in uncleaved etched samples of disk membranes and showed no change on light exposure. The internal hydrophilic region, however, was now smooth and showed no particulate structure while the inner rippled hydrophobic phase was observed to have a high density of particles of about 125 to 175 Å in diameter projecting 20 to 30 Å above the cleavage surface. In contrast to those seen on the interior hydrophilic surface before illumination, these particles showed no long or short term order and were randomly distributed on the membrane surface. Furthermore, the particles protruding from the hydrophobic surface after light exposure were arranged in what appeared to be aggregates of four to eight molecules and the average distance between centres in the hydrophobic region was smaller than that between particles arrayed on the internal hydrophilic surface of dark-adapted disk membranes.

Rhodopsin molecules

Identification of the observed particles as rhodopsin molecules is based on several points of evidence. The first is the very high density of particles on the membrane surface before and after light exposure, that is, one molecule per 5,400 Å^2. Other known molecular species would not be expected to occur in the disk photoreceptor at this membrane density. The particle density obtained is consistent with that calculated indirectly by X-ray diffraction[15] and microspectrophotometric studies on rhodopsin-containing disk membranes[16].

A second point of evidence is based on observations of membranes from which rhodopsin is extracted by detergent. Lightly sonicated (15 s with a Branson model JI7A sonicator, tuned to 20 kHz, yield of 250 W (acoustical)) disk membranes were extracted in the dark with 3×10^{-4} M aqueous digitonin for 30 min and then centrifuged. The absorbances at 500 nm of the resulting supernatant were taken and the pellet studied by freeze-cleave-etch electron microscopy. It was found that the amount of rhodopsin extracted increases from an initial ΔA_{500} of 0.004 for the first extraction to 0.467 for the third extraction. Electron micrographs of a pellet frozen in the dark after the first extraction revealed the same particle density on the internal hydrophilic disk membrane as untreated membranes with some slight membrane disruption. After the second extraction the number of molecules on the inner hydrophilic surface had markedly decreased to a particle density of one molecule per 14,000 Å^2. The third digitonin treatment disrupts the membrane appreciably, but there is a noticeable decrease in the particle density although it is difficult to quantify.

A third point of evidence derives from the fact that when membranes are fixed in 2% buffered glutaraldehyde in the dark, subsequent light exposure does not induce translocation of the particles to the hydrophobic phase, and the same 50 Å particles remain in linear arrays on the intradisk hydrophilic surface. This observation indicates that the integrity of the lipoprotein must be maintained if the translocation mechanism is to take place. These three points of evidence, though indirect, clearly suggest that the particles seen on the inner membrane are rhodopsin molecules.

On the basis of the observations reported here the native disk protoreceptor membrane seems to be a highly asymmetric protein-lipid bilayer with rhodopsin bound only on the internal disk membrane surface. When the outer hydrophilic membrane surface is visualised with the present technique, it appears, in many cases, to reflect the rippled texture of the hydrophobic phase beneath. On the other hand, no rippling is observed on the inner hydrophilic membrane surface after light adaptation, indicating that this surface is considerably more dense than the outer. These observations are in harmony with the X-ray diffraction studies of Worthington[15] which also suggest an asymmetry of electron density in the disk membranes.

In addition to the above studies, whole intact retina was also subjected to similar treatment. Retinae were studied as fully dark- or light-adapted tissue and in all cases exhibited behaviour identical to the isolated rods and disk membranes. Furthermore, rod outer segments subjected to hypertonic or hypotonic buffer treatment showed respectively shrinking or swelling of the intradisk space, but no deviation in the translocation behaviour within the membrane was observed as a result of this treatment.

Particle translocation

The degree of particle (rhodopsin) translocation is highly dependent on the extent of photobleaching (Fig. 2). Preparations of frog rod photoreceptors were photolysed for 0, 10, 30, 40, 80, 90 and 120 s and samples taken at each bleaching level for freeze-etch electron microscopy. Samples were also taken at each level of bleaching for extraction with 1% Emulphogene in 0.1 M hydroxylamine at *p*H 7.2 and a ΔA_{500} measurement made upon photobleaching of the extracted material. It was observed that the number of particles which were translocated from the internal hydrophilic disk surface to the hydrophobic region of the disk was directly proportional to the extent of photobleaching as measured by spectral ratio. This is further evidence that the particles that translocate in the disk membrane are indeed rhodopsin. In partially bleached samples, the A_{500} absorbance difference at 10 s illumination was 0.59 and at 90 s was 0.018, with the particle density on the hydrophobic surface changing from 15 per 25×10^6 Å^2 at 10 s to 125 per 25×10^6 Å^2 at 90 s (Table 1). When full bleaching occurred, a particle density on the hydrophilic surface was not wholly detectable or possible to quantify. Concomitant with this result, the ΔA_{500} was nearly zero.

Table 1 Absorbance and Particle Density Differences of Frog Rod Photoreceptors Differentially Bleached

Bleaching time (s)*	ΔA_{500}	Particle density† per 25×10^6 Å^2
0	0.068	5
10	0.059	15
30	0.045	35
40	0.042	50
80	0.028	90
90	0.018	125
120	0.008	135

* Exposed at 25° C at a distance of 4 foot from a standard 150 W light bulb with constant agitation of the sample.

† No. on median hydrophobic surface.

The experimental results described above are consistent with the view that the rhodopsin molecules are located on the internal, intradisk hydrophilic surface of the disk membrane. Illumination in conditions terminal at metarhodopsin II seems to initiate a translocation of the rhodopsin molecules to the interior hydrophobic region of the membranes with their subsequent aggregation. This apparent translocation is consistent with a change in the lipoprotein configuration of rhodopsin, manifest as a change in surface properties from a charged hydrophilic to an uncharged hydrophobic character. Such a process, clearly, could quite plausibly be associated with release of a transmitter substance such as calcium ion from the membrane. We stress, however, that although the evidence supporting the location of the rhodopsin molecules on the internal hydrophilic surface of the disk-membrane and their translocation to the median hydrophobic region on illumination is highly indicative, it is not at this stage unequivocal. Furthermore, it should be pointed out that the light levels employed in this study are far from physiological. Normally one might expect at most a few molecules in a given membrane to be bleached within the refractory period of the rod; whether the changes would be qualitatively the same in these conditions as under the conditions of the experiment is a moot point.

Volcanic Couples and Deep Mantle Plumes

MORGAN[1] has convincingly demonstrated a case for the upward rise of deep mantle material along narrow plumes which give rise to positive gravity anomalies and hot spots on the Earth's surface. These hot spots are reflected in large volcanoes and, as Wilson[2] suggested, where the lithosphere moves over hot spots, volcanic chains are produced. Perhaps the most striking support of Morgan's hypothesis are the parallel 'dog legs' in hot spot trajectories given by the Hawaii-Emperor, Austral-Marshall/Gilbert, and Tuamotu-Line chains, most readily explicable as generated by motion of the Pacific plate over three fixed hot spots.

Abundant support for the mantle plume hypothesis is becoming available from a number of approaches[3-6]. Gass[3], Burke and Wilson[4], and LeBas[6] have emphasised that African rifts can be explained by propagation of cracks produced by doming of the African craton, domes which they interpreted as resulting from upwelling mantle plumes. Schilling[7] has explained trace element and isotope variations of Iceland lavas on the basis of mantle plumes. Although this interpretation was criticised by O'Hara[8], independent geophysical evidence[9] also supports the concept of an Iceland mantle plume.

Although much geological, geophysical and geochemical evidence thus seems to be in favour of the hypothesis of deep mantle plumes, the ghost of Kelvin still walks among geophysicists and they have recently issued a statement of their disbelief[10]. Perhaps their disbelief is merely founded in semantics, and could be modified by an answer to Tozer's[11] 'cri de coeur' that someone "explain in terms that are meaningful to geophysicists in what respects the conventional geological pictures of rising magma differ from 'a thermal plume'." Although it is difficult to know what is meaningful to a geophysicist, the following observations on magma production may add some fuel to fire the geothermal plume debate.

Many large central volcanic edifices, both continental and oceanic, are formed from two (and rarely three or even four) volcanic centres spaced about 5 to 25 km apart. These I term 'volcanic couples', and several examples are given in Table 1. Note that many of these are shown as hot spots by Morgan[1].

Table 1 Comparison of Magma Types and Distances Separating Volcanic Centres of Particular Volcanic Edifices

Volcanic edifice (and reference)	Centre 1 basic magma type	Centre 2 basic magma type	Distance (km) between 1 and 2
Hawaii[12]	Kilauea Tholeiite	Mauna Loa Tholeiite	30
K, Ba and so on enriched relative to M. Loa tholeiite			
Réunion[13]	Piton des Neiges Olivine basalt	Piton de la Fournaise Olivine basalt	30
Tahiti[19]	Tahiti-Nui Ankaramite-basanite	Tairapu Basanite-ankaramite	30
Grande Comore[14]	Kartala Alkali basalt	La Grille Basanite	30
St Helena[21]	North-east volcano Alkali basalt	South-west volcano Alkali basalt	~10
Prince Edward Islands[13]	Marion Island Alkali basalt	Prince Edward Island Alkali basalt	30
Ba and K enriched relative to PEI alkali basalts			

An important point about the magmas of these volcanic couples is that some of the centres show fundamental petrological differences which cannot arise by low pressure petrological processes. These differences are mainly related to degree of silica saturation or enrichment in large cation trace elements, for example, Kilauea and Mauna Loa[12], Marion and Prince Edward Islands[13], alkali basalt-basanite (Grande Comore)[14], differences which are now generally interpreted as arising from high pressure processes such as eclogite[15] or orthopyroxene[16] fractionation or degree of partial melting[17]. This point is emphasised by the following discussion of two well documented examples:

The island of Grande Comore lies at the north-western end of a volcanic chain showing classic geomorphological features of age migration, with the oldest in the south-east and youngest in the north-west[18]. (I note that if these volcanoes result from plate movement over a hot spot, this motion was from north-west to south-east, about ninety degrees to the motion suggested by Morgan[1] but more or less parallel to that of Burke *et al.*[5].)

Grande Comore is formed by the coalescence of two volcanoes, Kartala in the south-east and La Grille about 30 km to the north-west. Kartala consists of an alkali basalt suite which shows coherent chemical variations caused by low pressure fractionation of olivine, augite and plagioclase. La Grille consists of a coherent suite of basanites, rich in high pressure ultramafic inclusions, which shows little or no effects of low pressure fractionation. There is a sharp field division between the two volcanoes, and little overlap in chemistry, suggesting independent origins with no mixing of the magmas during ascent. The magmas were interpreted to have arisen from different degrees of partial melting at depths below 60 km, with rapid rise to the surface along conduits definitely less than 15 km in diameter (halfway between the two craters) and probably much smaller[14].

The island of Hawaii consists of five separate volcanic centres separated from each other by distances around 30 km. Like Grande Comore it lies at the youngest end of a volcanic chain which serves as a kingpin in Morgan's mantle plume hypothesis[1]. The following discussion is concerned with only Kilauea and Mauna Loa, although in principle it applies to Mauna Kea, Hualalai and Kohala as well.

Both Kilauea and Mauna Loa have tholeiitic magmas, although the latter are depleted in K_2O and other large cation elements[12]. Wright[12] recognised two kinds of chemical variation in Kilauea lavas, short term variations between each summit eruption caused by high pressure fractionation of hypersthene from magma produced at depths below 60 km and long term variation resulting from a multistage process of fractionation of some combination of olivine, Cr-spinel, orthopyroxene and clinopyroxene, likewise at high pressures. He further suggests that differences between the 1969 Kilauea lavas and Mauna Loa lavas could be explained by the same high pressure fractionation processes which cause differences within Kilauea lavas. Although I accept Wright's interpretation as a reasonable possibility, it should be pointed out that precisely similar differences would result from differing degrees of partial melting.

Irrespective of the details of high pressure magmatic processes responsible, be they partial melting or crystal fractionation, many of the volcanic edifices above hot spots appear to be formed from two (or more) volcanic centres with fundamental differences in magma chemistry which result from high pressure processes. These magma batches may mix, as for Kilauea and Mauna Loa[12], or Tahaiti-Nui and Tairapu[19], or they may separate as in Grande Comore[14]. They generally originate at depths below 60 km and ultramafic inclusions in many indicate rapid ascent to the surface through narrow conduits. If Press's model[22] of oceanic upper mantle is valid and the low velocity zone is at an average depth of 150 km, and if Morgan[1] is correct in his suggestion that the lithosphere is 'de-coupled' at the low velocity zone, then it must be assumed that individual volcanoes cannot be directly related to mantle plumes as a source of magma, except in the special case where the volcano remained stationary above the plume, as suggested by Schilling[7] for Iceland. If the plume itself were contributing material to the volcanoes one would not expect such subtle differences to persist in such precise spatial relationships. Since Iceland-type magmatic differences are found in areas which were not stationary and therefore not fed directly by the mantle plume, one must agree with O'Hara[8] that a direct mantle plume source is unnecessary to explain the Iceland magmas. Further, these relationships suggest that the magmas did not rise directly from the low velocity zone which would presumably be a zone of homogenisation.

Given that deep mantle plumes are not necessarily direct sources of magma, there is less reason to assume that plumes are the result of upward mass transport, that is, of mantle convection. The only necessity for the observed linear patterns of magma generation is a concentrated heat source at the base of the lithosphere—a 'hot spot' or 'thermal plume'. These distinctions between mantle plumes and magma generation may satisfy Tozer's request[11] for terminological clarification, although it is clearly up to the geophysicists to answer some of the resulting questions. For example, do the gravity anomalies which Morgan[1] explained as resulting from mantle plumes have any equally reasonable alternative explanations? Is it possible to have thermal plumes without mass transport, perhaps by zones of high thermal conductivity or concentrated diffusion?

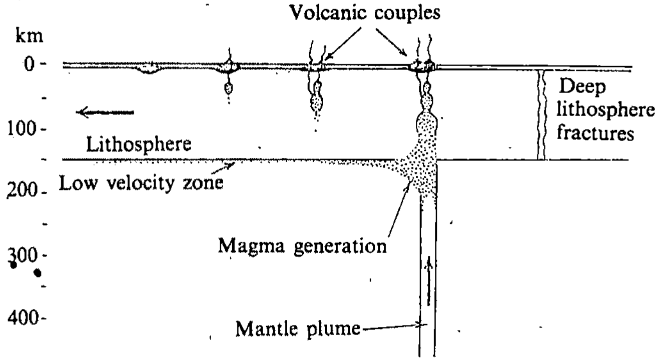

Fig. 1 Magma generated above the mantle plume (either thermal or convective) in or below the low velocity zone is collected in magma chambers and migrates towards the surface after fractionation at a number of intermediate staging areas. Magmas tapped along deep fractures from different staging areas form adjacent volcanoes of different compositions. With migration (to the left) of lithosphere plate above the plume, the magma source is smeared out, the supply of magma is cut off and volcanism is restricted to progressively more extreme fractionation products and eventually terminated entirely, and a new volcanic edifice is formed as other lithosphere 'fractures' (or at least weaknesses) pass over the plume. (Modified from Wilson[2] and Wright[12].)

I thank R. K. Stevens for discussion.

Lyoluminescent tissue equivalent radiation desimeter

WHEN some irradiated solids are dissolved in water or certain other solvents, a light emission takes place which, following Wiedemann[1], we call "lyoluminescence." With inorganic materials such as alkali halides, the reactions of trapped electrons from F centres are responsible for the light emission[2]. In the case of some organic materials such as saccharides, trapped free radicals are involved in the process of lyoluminescence[3,4].

It is possible to measure doses between 1 and 10^7 rad with an accuracy of 5% using NaCl and water as a solvent[5]. The stored lyoluminescent energy in NaCl decreases only by 15% after 7 month of storage but it is sensitive to optical and thermal bleaching. Furthermore, the effective atomic number of NaCl is approximately 16, differing considerably from that of human tissue (about 7.5).

The investigation of monosaccharides including glucose, xylose and mannose has demonstrated the stability of the trapped free radials. There was no decrease in their lyoluminescence over 7 month. Their performance has been evaluated with respect to the sensitivity to radiation and stability against thermal annealing. They show linear dependence with doses up to 100 krad. The lower dose detected by the apparatus used (Fig. 1) was 100 rad (ref. 6).

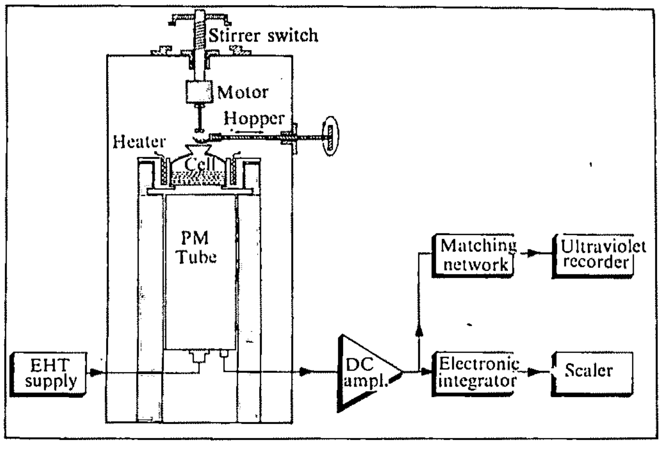

FIG. 1 The lyoluminescence reader

From the shape of the emitted light decay curve, it is evident that there are two or more diffusion controlled reactions involved which differ in their time scale. Here we deal with the short lived component (integrated for 3 s) because it has a much greater intensity than the long lived one.

With NaCl, when using TlCl or fluorescein solution instead of water, the enhancement of light takes place but only at higher doses. With saccharides these fluorescent systems have no effect.

It would be possible to use the lyoluminescence of saccharades for clinical dosimetry if their sensitivity could be enhanced. Therefore the chemiluminescent reactions of luminol (3-aminophthalhydrazide) with oxidising agents was utilised[7,8]. Using a ^{60}Co-γ-source, irradiated saccharides give a bright blue light (≈ 4,460 A°) when they are dissolved in luminol solution. The light enhancement compared to that of water is about 10^6 times. The best results were obtained with trehalose. $2H_2O$ (Fig. 2). It shows an approximately linear light output between 1 and 60^6 rad, and the lower limit is probably controlled by the level of impurities in the system, as luminol is sensitive to metallic ions such as Cu^{2+} and Co^{2+} in higher oxidation states. The slope of the curve is dependent upon the concentation of luminol and the pH of the solution.

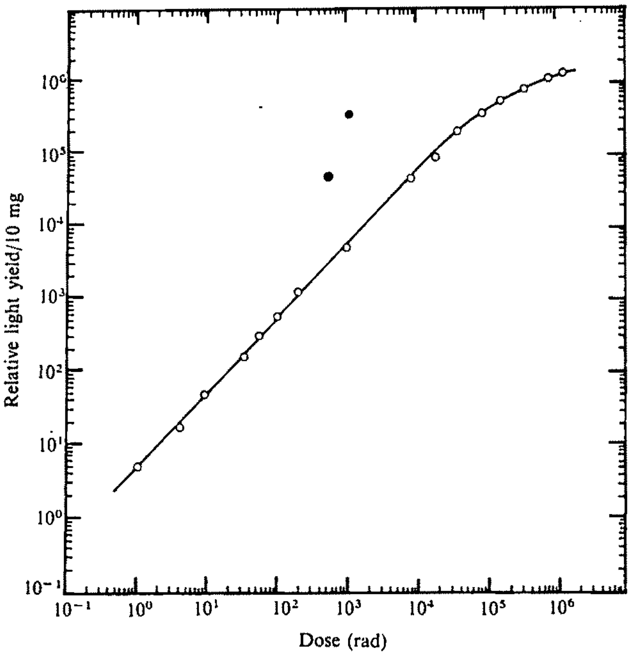

FIG. 2 Integrated light output versus radiation dose, when trehalose. $2H_2O$ was dissolved in 5 ml of luminol solution (125 mg luminol, 1.25 g Na_2CO_3 and 2.5 mg chlorohemine in 1 l deionised water).

It is quite likely that the oxidising species responsible for exciting luminol are formed as a result of free radical reactions with dissolved or adsorbed oxygen in the system. For example, (ROO) is capable of oxidising luminol which is accompanied by the emission of light. Oxidising species were, however, reported to be formed when irradiated saccharides are dissolved in water, and the possibility of H_2O_2 or ROOR formation is not ruled out[9,10]. Thus trehalose. $2H_2O$ which is a fairly true tissue equivalent material makes a good candidate for lyoluminescence dosimetry.

We thank Professor J. H. Fremlin for his advice. This work was supported by the Science Research Council.

Newfoundland Ophiolites and the Geology of the Oceanic Layer

THE significance and origin of ophiolites is a matter of interest to geologists. Many investigators interpret ophiolites as slices of oceanic crust which have been tectonically emplaced in orogenic belts[1-7]. Moores and Vine[5], Dewey and Bird[6], and Coleman[7] have proposed just such an origin for ophiolites as geographically diverse as Cyprus, Newfoundland and the Western United States. If ophiolites are representative of the geology of the oceanic crust, then they provide direct access to samples of oceanic crust and the underlying upper mantle—rocks at present inaccessible except for the fortuitous catch in dredge hauls located on tectonic escarpments of the ocean floor. Although we accepted the proposition that ophiolites, if well preserved and not altered by events unrelated to lithosphere accretion, are representative of oceanic crust, we wished first to test this proposition by observing whether representative ophiolite samples had measured velocities compatible with the seismic layering defined for oceanic crust. If the velocities of ophiolite samples were compatible with the range of seismic velocities recorded for oceanic crust, then we hoped to use the ophiolite measurements to understand better the details of the seismic layering of oceanic crust. Here we summarise the acoustic velocity data obtained from metadolerites, gabbros and cumulate gabbros from the Mings Bight ophiolite assemblage[6] located along the northern coast of Newfoundland. A more detailed discussion of these ophiolite samples (J. J. P., in preparation) will give a thorough presentation of petrography, sample density and measured compressional wave velocity of each sample at pressure intervals from 1 atm to 7 kbar.

Seismic models of the oceanic crust have been formulated principally from the interpretation of seismic reflection and refraction data. The velocity structure of the oceanic crust consists of three layers[8]. The oceanic layer (layer 3) is characterised by velocities in the range 6.7 to 6.9 km s^{-1}. Although most reported velocities for the oceanic layer are in this range, the full range of reported velocities is 6.1 to 7.0 km s^{-1}. Overlying this is oceanic basement (layer 2), which exhibits a broad range of velocities (3.5 to 6.0 km s^{-1}), most of which lie in the range 4.4 to 5.6 km s^{-1}. The uppermost layer (layer 1) consists mainly of consolidated and/or unconsolidated sediments having velocities of 1.5 to 3.5 km s^{-1}. Recent seismic refraction studies, however, indicate that the velocity structure of the oceanic crust is more complex than the early studies suggested. Sonobuoy refraction studies of the Reykjanes Ridge show that oceanic basement (layer 2) is made up of two velocity layers[9]. The upper portion (layer 2A) has a recorded velocity range of 2.33 to 3.84 km s^{-1}. The lower portion (layer 2B) is characterised by a velocity range of 4.05 to 5.92 km s^{-1}. Sonobuoy refraction studies in the Pacific show that the oceanic crust (layer 3) is made up of two velocity layers[10,11]. The upper layer is 2 to 3 km thick and has a velocity range of 6.5 to 6.8 km s^{-1} and overlies a lower layer 2 to 5 km thick with a recorded velocity range of 7.0 to 7.7 km s^{-1} (average 7.4 km s^{-1}).

To interpret these seismic models of oceanic crust in terms of lithological units, it is necessary to measure in the laboratory the physical properties of representative samples of rock types recovered from oceanic escarpments. Comparisons of seismic refraction results with laboratory measurements at confining pressures equivalent to *in situ* lithostatic pressures provide information about the possible composition of velocity layers. Several investigators have made laboratory measurements on oceanic samples and have proposed geological models of the oceanic crust. Based on studies of basalts, meta-basalts and meta-gabbros, Christensen[12], Christensen and Shaw[13] and Barret and Aumento[14] proposed that the oceanic crust is composed of basalt and meta-basalt (layer 2) which overlie meta-gabbro (layer 3). We have recently presented the results of a study of basalts, meta-basalts, meta-gabbros, gabbros and serpentinites recovered from the escarpments of the Kane

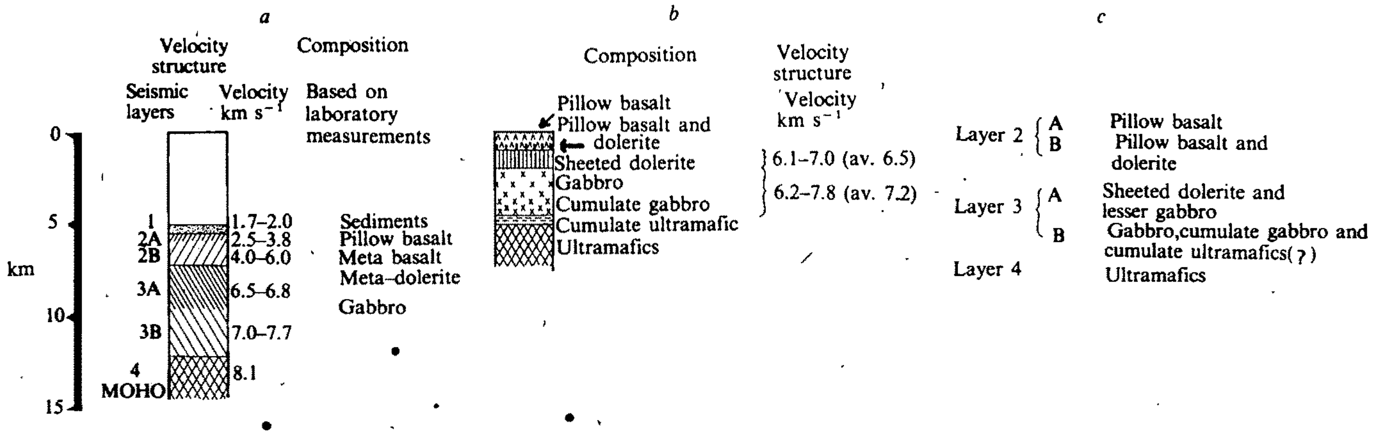

Fig. 1 *a*, Generalised velocity structure of the oceanic crust and the inferred composition of the oceanic crust based on a correlation of velocities measured in the laboratory on dredged rocks with velocities measured by seismic refraction methods. *b*, Generalised geology of Mings Bight ophiolite complex and the measured velocity range of representative dolerite and gabbroic samples. *c*, Correlation between Mings Bight ophiolite assemblage and the layering of the oceanic crust based on laboratory compressional wave velocity measurements.

Fracture Zone[15]. Our results, when integrated with the standard velocity structure of the oceanic crust, led us to propose a slightly different model for the oceanic crust (Fig. 1*a*). We proposed the following structure from top to bottom: layer 2A (2.5 to 3.8 km s^{-1} is made up of a fractured pile of glassy pillow basalts; layer 2B (4.0 to 6.0 km s^{-1}) is made up of zeolite and greenschist facies meta-basalt and minor meta-dolerite; layer 3 (6.7 to 6.9 km s^{-1}) is made up predominantly of unaltered gabbro. The measured velocities of meta-gabbro (greenschist and amphibolite facies), serpentinised peridotite and actinolite-rich rocks were not compatible with the generalised velocity structure of the ocean basins, suggesting that these rock types do not occur in abundance within the oceanic crust but instead reflect tectonic processes associated with the escarpment on which they were sampled. We were intrigued with the seismic refraction results of Maynard[10] and Sutton *et al.*[11] which indicated a high velocity layer ($>$7.0 km s^{-1}) in the lower portion of layer 3. Although only one of the measured gabbro samples had a velocity of more than 7.0 km s^{-1}, we suggested that cumulate gabbros or pyroxenites could be responsible for the high velocity component of layer 3. Rock types of this character had been reported from some fracture zones[16,17].

The ophiolite samples we studied were obtained from the Mings Bight ophiolite complex in north-eastern Newfoundland. These rocks form a steeply dipping zone between the Fleur de Lys metamorphic complex of Cambrian age and Lower Devonian clastics and volcanic rocks. The ophiolite rocks show tectonic contacts and appear to have been tectonically emplaced during the Middle Devonian[18]. This location is ideal because it represents a fully developed ophiolite complex in which all units (see Fig. 1*b*) are represented and in which the rocks have been relatively unaffected by metamorphic episodes associated with the emplacement of the assemblage. Also, as a consequence of locale and climate, ice wedging and wave action cause the altered rock surface to be spalled off and washed away exposing unweathered rock for sampling.

Depending on the sample size, two or three cores, whose axes were oriented so that they were mutually perpendicular, were cut from each sample using a small (0.5 inch) diamond corer. Specimen lengths ranged between 1 and 2.5 inch. The ends of each core were cut smooth and parallel to within 0.001 inch of each other, yielding right circular cylinders. The specimens were jacketed in thin copper foil (2 ml thick) and all joints were sealed with soft solder. The main function of the copper jacket was to prevent entry of pressurising fluid into the pores and cracks of the specimen, so that measurements were made under zero pore pressure, and to serve as electrical shielding, thereby improving the signal-to-noise ratio. To measure the travel time of acoustic energy transmitted through the specimens, a variation of the pulse transmission method of Birch[19] as described by Mattaboni and Schreiber[20] was used. A precision of 1% could be obtained.

The velocity of sound propagated through rocks at low confining pressures depends on the presence of pores and cracks and on their geometry[21,22] resulting in the measurement of markedly lower velocities than would be measured for theoretically dense materials of the same composition. For this reason velocity was measured as a function of hydrostatic pressure. Typically, the greatest effect on velocity occurs within the first 2 kbar of applied pressure. The slope of the velocity curve asymptotically approaches that for theoretically dense material at confining pressures in excess of 2 kbar. The velocities reported here are those determined at 1.5 kbar, which is within the range of *in situ* lithostatic pressure for the oceanic layer (layer 3A, 3B). The density of the specimens was calculated from direct measurements of their lengths, diameters and masses, and is regarded as accurate to within 1%.

The results of thirty-two measurements on thirteen samples of gabbro and cumulate gabbro are shown in Fig. 2. We display the individual measurements, rather than averaged results, to emphasise the spread in the velocity range that might be measured for a given rock type. The leucocratic to melanocratic gabbros commonly exhibit ophitic textures and are composed in general of calcic plagioclase and clinopyroxene with minor vein and interstitial serpentine, fibrous amphibole and chlorite. The plagioclase of the gabbros is often saussuritised. The cumulate gabbros are characterised by bands enriched in pyroxene and olivine within the gabbro. Minor serpentine and fibrous amphibole are associated with the cumulate gabbros. The calculated densities of the gabbro and cumulate gabbro specimens range from 2.9 to 3.2 g cm^{-3}. The compressional wave velocity range of these gabbroic samples at 1.5 kbar confining pressure is 6.1 to 7.8 km s^{-1}. The majority of the samples have measured velocities above 6.9 km s^{-1} with a well defined peak at 7.4 to 7.5 km s^{-1}. The six samples with velocities below 6.9 km s^{-1} exhibit a larger amount of fibrous amphibole and chlorite than the higher velocity samples. We observed in a study of oceanic gabbro that the development of amphibole and chlorite at the expense of primary mineral phases decreases the compressional wave velocity[15].

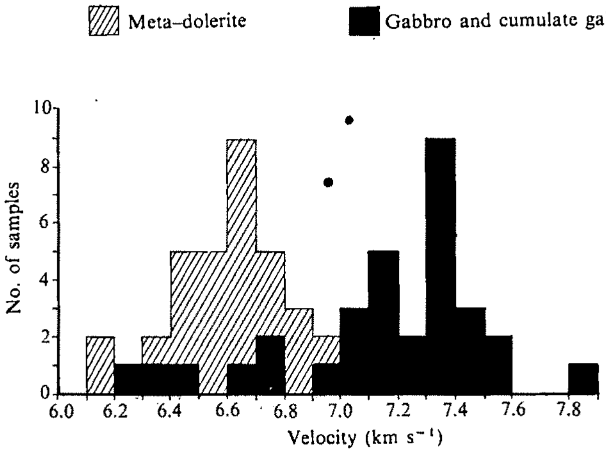

Fig. 2 Histogram of measured velocities for thirteen samples of gabbro and eleven samples of meta-dolerite (greenschist facies) from Mings Bight ophiolite complex. Two or three specimens, oriented so that they were mutually perpendicular, were cut from each sample. The measured velocity for a given specimen displayed individually. The velocity results shown here were measured at a confining pressure of 1.5 kbar which is within the range of *in situ* lithostatic pressure for the oceanic layer (layer 3).

The results of twenty-seven measurements on eleven samples of greenschist facies meta-dolerite are shown in Fig. 2. The meta-dolerites often exhibit relict sub-ophitic textures and are composed of plagioclase, sometimes enriched in Na, and pyroxene with varying amounts of epidote, chlorite, actinolite and quartz. The calculated densities of the meta-dolerite samples vary from 2.8 to 3.0 g cm^{-3}. The compressional wave velocity range of the dolerites at 1.5 kbar confining pressure is 6.1 to 6.9 km s^{-1}. At a confining pressure of 0.75 kbar (calculated *in situ* lithostatic pressure range for layer 2) the velocities of the dolerites range from 6.0 km s^{-1} to 6.9 km s^{-1}, indicating that dolerites of the sheeted dike layer are not representative of seismic layer 2B (velocity range of 4.0 to 6.0 km s^{-1}).

The measured compressional wave velocities of the dolerite and gabbro samples range from 6.1 to 7.8 km s^{-1}. Seismic refraction measurements of layer 3 (A and B) of the oceanic crust show a similar range of velocities[8]. This correlation supports the interpretation that ophiolite assemblages are representative of oceanic crust. The histogram of measured compressional wave velocities (Fig. 2) exhibits a distinct bimodality with a dolerite peak at 6.6 to 6.7 km s^{-1} and a gabbroic peak at 7.4 to 7.5 km s^{-1}. These velocities compare well with the bimodal distribution of seismic velocities recorded for layer 3A (6.5 to 6.8 km s^{-1}) and 3B (7.0 to 7.8 km s^{-1})[10,11]. Accepting the proposition that ophiolites are representative of oceanic crust, we conclude from our data that the upper portion of the oceanic layer (seismic layer 3A) is composed predominantly of sheeted dolerite and possibly some gabbro. The lower portion of the oceanic layer (seismic layer 3B) is composed predominantly of gabbro and cumulate gabbro. Based on velocity alone it is difficult to say conclusively whether the cumulate ultramafic rocks (pyroxenites) belong with layer 3B or upper mantle. We sampled several pyroxenities for this study but all the samples have been serpentinised, resulting in anomalously low velocity. Some published values of unaltered pyroxenites at 1.5 kbar confining pressure indicate that rocks of this type have velocities in the range 7.3 to 7.7 km s^{-1} and therefore could be a constituent of layer 3B. More work is needed to define the velocity range of pyroxenites but, based on the results to date, we propose that the cumulate ultramafics belong with the gabbroic rocks of layer 3B.

Poster[23] has recently reported results on velocity measurements of the Troodos ophiolites. His results for three gabbros are similar to those reported here; two of the three diabase measurements, however, are lower than those reported here, presumably because of greater alteration. Nonetheless, he arrived at a conclusion similar to our model. If the ophiolite assemblages are analogues of the geology of the oceanic crust, then it is clear that the petrological associations within the oceanic basement and oceanic layer are complex. Indirect geophysical measurements of the physical expression of the oceanic layers do not have the resolution to resolve the inherent complexity of these layers and therefore careful study of ophiolite assemblages may hold the key to the details of oceanic lithosphere geology.

We thank Professors J. F. Dewey and J. Bird and Mr W. S. F. Kidd for their assistance in the collection of the ophiolite samples. Drs J. F. Dewey, W. B. F. Ryan and W. Pitman read the manuscript and made valuable suggestions. Support for this research came from a National Science Foundation grant (P. J. F.), an Office of Naval Research grant (P. J. F.), the City University of New York Research Foundation (E. S.) and the State University of New York Research Foundation (P. J. F.).

Molecular Complexity of Water Vapour and the Speed of Sound

SEVERAL real atmosphere and laboratory spectroscopic measurements[1-3] suggest that water vapour near saturation contains polymeric molecules of which the concentration rises with increasing pressure and decreasing temperature. Existing *PVT* data which could support this conclusion lack the necessary accuracy for temperatures which are approaching atmospheric values and no related speed of sound measurements seem to be available for the conditions of interest.

We give here a preliminary report of some new measurements derived from observations of the transit time of sound pulses in water vapour. The measurements were made at a fixed temperature and the vapour pressure was varied from low values up to values close to saturation. Results are shown in Fig. 1.

A gas such as neon, which shows no molecular association, gives speed values which are independent of pressure, so the trend we observe in water vapour of speed decreasing with increasing pressure is taken as showing that it contains molecular complexes. The speed decrement with pressure becomes greater as temperature is lowered. To compare with the observations we have considered a model in which the complexes are all taken to be dimers. This model will be represented by straight lines in the plot since the speed of sound varies as the square root of gas density and dimer concentration will vary as its square. The fractional dimer concentration is measured by the slope of these lines and at 50° C and 90% saturation we find a value of 8×10^{-3}. The temperature dependence of the slope is a measure of the dimer binding energy for which a value of 0.5 ± 0.1 eV per dimer molecule is found.

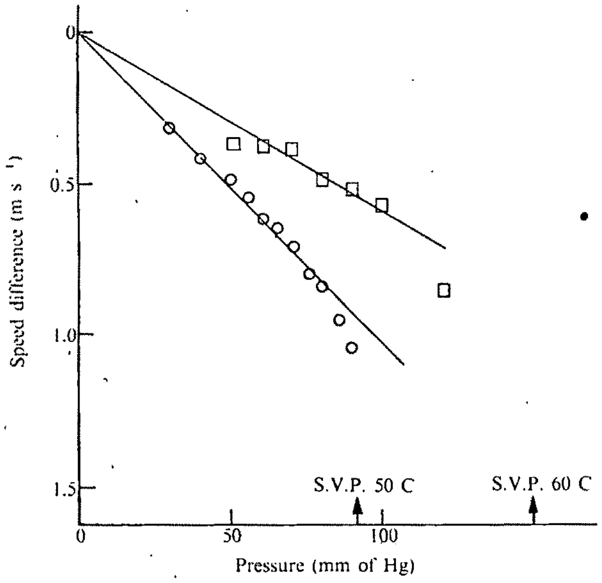

Fig. 1 Speed of sound in water vapour. The ordinate is the difference between the observed speed and the speed, appropriate to the temperature, extrapolated to zero pressure. □, 60° C; ○, 50° C.

The model used for analysis is only a first approximation and is probably oversimplified: the values also are tentative and subject to confirmation when the measurement technique can be refined, but these speed of sound measurements clearly show molecular complexity in water vapour at temperatures approaching tropospheric values.

Light Sensitivity of Tests for Cadmium on Ceramic Tableware

Many countries, including Ireland, Great Britain and the United States, have introduced national standards aimed at controlling the amount of lead and cadmium which can be leached into food from ceramic tableware[1-3].

Most countries including those mentioned above favour a cold test while others, notably Denmark, favour a boiling test of shorter duration[4]. The cold test usually involves filling the article with 4% acetic acid and allowing it to stand for 24 h. Limits are set for the concentration of lead and cadmium in the resultant leaching solution. In the Irish and United States tests, the limits are set at 7 p.p.m. for lead and 0.5 p.p.m. for cadmium. The British Standard (BS) for ceramic flatware is 20 and 2 p.p.m. for lead and cadmium respectively, those for hollow ware below 1,100 ml are 7 and 0.7 p.p.m. for lead and cadmium respectively and the BS limits for hollow ware of 1,100 ml and above are 2 and 0.2 p.p.m. for lead and cadmium respectively. The method of test is, however, very similar to that used in the American and Irish tests.

The series of experiments reported here were carried out on whiteware pottery with a lead-bearing glaze on which was applied a multicoloured silk-screen onglaze pattern, known to contain cadmium. A series of plates, decorated, heat treated and tested at room temperature in a similar manner in the absence of light, gave values of 0.17 ± 0.06 p.p.m. for cadmium. But, if plates from a similar batch were tested under daylight conditions or under artificial light at similar temperatures, results up to 2.5 p.p.m. could be recorded depending on the duration, intensity and wavelength of the radiation allowed to fall on the plates in the 24 h period. The results also indicate that significant leaching can occur in brightly lit conditions when the 4% acetic acid solution is replaced by deionised water as the leaching solution. Results of 0.5 p.p.m. have been recorded, once again depending on the duration and intensity of the light in the 24 h period.

Throughout the experiments no change was noted in the results for the amount of lead leached, which remained at 1.2 ± 0.4 p.p.m. When distilled water was used, no lead was leached into solution.

There is also evidence which indicates that the boiling test used in Denmark can be similarly light sensitive.

We suggest that, in the case of the series of results reported here, the light sensitivity of the test is due to the photooxidation of insoluble cadmium sulphide to soluble cadmium sulphate. Cadmium sulphide has been shown by X-ray diffraction to be present in the onglaze decoration. Clearly, articles may pass or fail the various national specifications according to the light conditions in which the test is carried out. Further details of the results quoted here will be published elsewhere.

We thank the Research Development Department of Arklow Pottery for their support of this project.

BIOLOGICAL SCIENCES

Absorption of Cadmium, Copper and Zinc by Dog Whelks in the Bristol Channel

SEVERAL independent studies have established that unusually high concentrations of certain heavy metals, most notably cadmium, are found in littoral flora and fauna of the Bristol Channel[1-4]. An experiment by Peden *et al.*[5] established that the concentrations of cadmium and zinc in dog whelks (*Nucella lapillus*) did not markedly decrease after transferring specimens to clean water for seven weeks. Bristol Channel dog whelks have shells with an elongated shape, clearly distinguishable from the usual shell shape. This feature, together with the fact that dog whelks move very little (J. H. Crothers, personal communication), makes the species ideal for studying the absorption of metals.

In April 1973, 120 dog whelks with the usual shell shape were collected at Beer, in Dorset (National Grid reference SY235895). Ten specimens were analysed for cadmium, copper and zinc, and the rest were released in a clearly identifiable area of approximately 500 m^2 at St Andrew's Head, North Somerset (National Grid reference ST324662). The area was below the *Fucus serratus* zone (below the Mean Low Water Level), where the local dog whelks live, feeding on acorn barnacles (*Elminius modestus* is the dominant species here). Specimens were collected after 1 week and thereafter at monthly intervals. The survival rate was good, although some fatalities were noticed at the end of June, when the spring tides uncovered the animals in early afternoons in hot sunlight. A similar proportion of fatalities was noticed among the local dog whelks. Even after 6 months no specimen was found outside the release area.

After removing the shell, each specimen was weighed, dried at 105° C for 24 h, reweighed and dissolved in 5 cm^3 concentrated nitric acid (AR grade). The solution was diluted to 25 cm^3 with double-distilled water, and the metal concentrations were determined by atomic absorption spectrophotometry (Table 1).

Several common limpets (*Patella* sp.) were collected from Beer at the same time as the dog whelks. The shells were scratched with a cross and released at St Andrew's Head on a rock in the *Fucus serratus* zone. Local limpets from the same spot were collected at the time of transplanting the specimens. The survival rate was poor and the small collections were made at irregular intervals (Table 2).

The concentration of cadmium in the dog whelks increased at an appreciably slower rate than that of zinc. At the end of the fourth month, the cadmium concentration was significantly lower than that in the native specimens, but it was still increasing steadily. By the end of the second month, the zinc concentrations were statistically indistinguishable from those in the native specimens. The copper concentrations remained considerably less than those in the native specimens.

Because of the small number of specimens analysed, only speculative observations about the uptake of metals by limpets

Use of Sulphur-coated Urea for Revegetation of Blast Furnace Slag

Apart from studies in the Lower Swansea Valley[1–4] there has been no attempt to investigate the factors inhibiting plant growth on blast furnace slag. This material is probably second only to colliery spoil as a mineral waste problem in the United Kingdom.

Recent investigations on the revegetation of blast furnace slag in Lancashire have shown that growth is limited by high *p*H (10.2 to 10.5) and serious deficiencies of the major nutrients nitrogen and phosphate (my unpublished work). Although exposure of the waste causes a reduction in *p*H at the surface due to leaching of hydroxides, the underlying material remains highly alkaline (Table 1). Consequently, plant growth is restricted by the limited depth of the hydroxide-free rooting substratum. The waste is also highly porous so that soluble nutrients such as nitrogen are quickly lost from the planting medium.

The provision of adequate phosphate for growth establishment is not difficult and some slags may even contain this nutrient. For the reasons described, however, soluble inorganic forms of nitrogen are most inefficient when used on this waste. I have therefore investigated the efficiency of sulphur-coated urea as a slow release nitrogen source in order to achieve a visually acceptable grass cover on the waste without involving the provision of expensive manurial or soil top coverings.

A randomised block experiment was set up on a levelled tip site with a surface *p*H of 9.0 after some 4 months of exposure. Five different nitrogen treatments were investigated, namely, nil N, 50 and 100 kg ha^{-1} N as urea, and 50 and 100 kg ha^{-1} N as sulphur-coated urea. Phosphate was applied to all the plots at 75 kg ha^{-1} P_2O_5 and *Festuca rubra* which is relatively tolerant of the waste conditions[4] was sown in June 1972. In early September 1972 there was evidence of phosphate deficiency. Accordingly, the plots were refertilised with 125 kg ha^{-1} P_2O_5 and three nitrogen treatments were superimposed on the initial treatment regimes according to a split plot design. These were nil N, 100 kg ha^{-1} N as urea, and 100 kg ha^{-1} N as sulphur-coated urea. In this way, the efficiency of slow-release nitrogen was investigated as an initial and maintenance fertiliser treatment.

Table 1 *p*H Profile of Blast Furnace Slag after 12 Months Exposure

Depth (cm)	*p*H
0	8.1
2.5	9.0
5.0	10.2
7.5	10.3
10.0	10.5
15.0	10.4

All the plots were assessed visually by four independent observers in late May 1973. The criterion of assessment was overall visual acceptability as affected by percentage cover of the substratum, colour and uniformity of growth, and sward density. Each of the experimental grass plots was designated an index of acceptability within the range 1 to 10 and the results were assessed by statistical analysis.

Table 2 shows the mean indices of growth acceptability in relation to the initial and secondary nitrogen treatments. It can be seen that overall growth was still influenced by the initial nitrogen applications at this time. The residual slow-release nitrogen responses were significantly better than those obtained by the use of soluble urea nitrogen. It is interesting that the performance from the low rate of slow-release nitrogen was superior to that from the high rate of urea nitrogen. Considering the effects of the second fertiliser treatments, slow-release nitrogen was again significantly better than uncoated urea. Therefore, both initial and maintenance applications of slow-release nitrogen give better growth than soluble nitrogen.

Table 2 Mean Indices of Visual Acceptability as Affected by Nitrogen Fertilisation

Initial N treatments	Nil	N1	N2	SN1	SN2
	3.30	3.83	4.43	4.73	5.37
	l.s.d. at $P=0.05=0.53$				
Second N treatments	Nil		N		SN
	1.54		4.94		6.52
	l.s.d. at $P=0.05=0.41$				

N, Urea nitrogen.
SN, Sulphur-coated urea nitrogen.

Table 3 shows the interactions of the initial and second nitrogen treatments. Clearly, nitrogen is better applied after planting if one fertiliser treatment only is involved. For good growth, however, it is obviously necessary to provide two additions, both of which should be in slow-release form for best results. If soluble and slow-release nitrogen treatments are combined, it is preferable to use the slow-release form at the second fertilisation rather than the first.

Table 3 Mean Indices of Visual Acceptability in Relation to Initial and Maintenance Nitrogen Regimes

		Maintenance N		
		Nil	N	SN
	Nil	1.00	3.80	5.10
Initial N	N	1.00	4.80	6.60
	SN	2.35	5.65	7.15
		l.s.d. at $P=0.05=0.91$		

Indices for initial nitrogen treatments are means of high and low levels of application.

The critical limit of visual acceptability at the time of assessment was represented by an index of about 6.0. Since this was only exceeded following treatment with slow-release nitrogen, it is clear that the choice of slow-release against soluble nitrogenous fertiliser can determine the success or failure of acceptable vegetation establishment on blast furnace slag. These results may have important implications in the revegetation of other industrial waste materials where similar problems of substrate toxicity and adverse nutrient retention are involved.

N-terminal Acetylation of Histone-like Nascent Peptides on Rat Liver Polyribosomes *in vitro*

Several proteins are known to have the amino terminus blocked by acetyl radicals[1]. At least six of these proteins, including the f_{2a} histones, have an N-acetylserine terminus[2]. The mechanism by which the acetyl group becomes attached to these molecules is not well understood. Proposals suggesting the initiation of protein synthesis by acetylated amino acids as a general mechanism in eukaryotes[3] have been refuted[4]. However, a role of N-acetyl amino acids in the initiation of the synthesis of certain specific proteins cannot be ruled out[5]. An explanation for the presence of N-acetyl amino acids at the amino terminus of proteins is the existence of an acetylating enzyme specific for certain N-terminal sequences in proteins or growing polypeptides chains. The finding of an acetyltransferase activity bound to rat liver ribosomes and specific for the N-terminal amino acid of some proteins associated with the ribosomes[6] offers an appropriate system for the study of the alternative mechanism. We report here the analysis of histone-like nascent peptides acetylated *in vitro* in liver polyribosomes prepared from rats hepatectomised 22 h before being killed. The results indicate that acetyl groups can be attached directly to N-terminal serine residues of nascent peptides in the absence of the initiation of protein synthesis.

The proposed role of N-acetylserine tRNA as an initiator of the synthesis of f_{2a} histones results from the finding of N-acetylserine in growing peptide chains isolated from regenerated rat liver and the finding of N-acetylserine tRNA in the cytoplasmic extracts from the same source[5]. The first of these two observations indicates that acetyl groups are attached before histone synthesis is completed, but it does not necessarily imply an initiation mechanism, since the N-terminal acetylation of polypeptide chains during chain elongation gives the same result. To explore this possibility, polyribosomes prepared from rats partially hepatectomised 22 h earlier were acetylated *in vitro* by incubation with 1-^{14}C-acetyl coenzyme A (ref. 9). Polyribosomes were also acetylated *in vivo* with ^{3}H-sodium acetate[8] under conditions in which N-terminal acetylation of histone nascent peptides is known to occur[5]. Aliquots of polyribosomes acetylated *in vivo* and *in vitro* were analysed by sodium dodecyl sulphate-acrylamide gel electrophoresis to compare the distribution of acetyl radicals among the proteins resolved in this system. As Fig. 1 shows, two groups of acetyl proteins with molecular weights of 30,000 and 10,000–20,000 were present in polyribosomes acetylated *in vivo* and *in vitro*. We also found that most proteins acetylated *in vivo* had a molecular weight greater than 30,000, and no correspondence with the proteins acetylated *in vitro*. The reason for this disparity is not known.

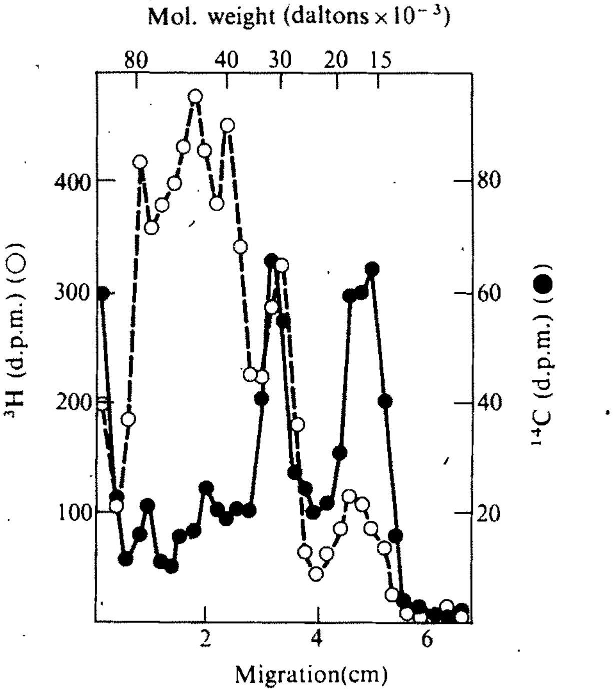

Fig. 1 Sodium dodecyl sulphate acrylamide gel electrophoresis of polyribosomes acetylated *in vivo* and *in vitro*. Liver polyribosomes were prepared[7] from rats 22 h after partial hepatectomy. One group of rats was given 10 mCi per rat of ^{3}H-sodium acetate before death to obtain polyribosomes acetylated *in vivo*[5]. Polyribosomes from untreated rats (250 A_{260} units) were acetylated *in vitro* by incubation with 0.05 mCi of 1-^{14}C-acetyl coenzyme A in the presence of 0.05 M Tris-HCl, *p*H 7.5, 0.1 M KCl and 1 mM dithioerythrol[9]. Aliquots (4–5 A_{260} units) were analysed in 10% acrylamide gels by electrophoresis in the presence of 0.1% sodium dodecyl sulphate and the radioactivity in the gel fractions was counted as described[9]. The solid and open circles correspond to ^{14}C and ^{3}H-radioactivity, respectively.

To study the presence of acetyl radicals in the histone-like nascent peptides, we incubated the polyribosomes with puromycin in the presence of a high concentration of salt and they were then pelleted by high speed centrifugation. The growing peptides released by puromycin were then treated with 0.25 N sulphuric acid to extract the basic proteins and polypeptides, which were then dialysed for 48 h against 0.025 N sulphuric acid, precipitated with 4 volumes of absolute ethanol in the cold and dried under vacuum. (About 2.5 mg of dried product is recovered from 20 g of wet liver.) In terms of radioactivity, the recovery was less than 5% of the total radioactivity found in polyribosomes. The basic protein and growing polypeptides in the acid extract were characterised in two acrylamide gel electrophoretic systems. In sodium dodecyl sulphate electrophoresis (Fig. 2*A*), all the acetyl radioactivity was found associated with proteins having apparent molecular weights of 10,000–20,000; in this range of molecular weights is found histone f_{2a} (ref. 11) or its nascent peptides near completion. Electrophoresis in the presence of urea at *p*H 2.5 (Fig. 2*B*) revealed that most of the acetyl protein in the sample had a mobility close to the histone standards. From this study we conclude that most of the acetyl protein released from polyribosomes by puromycin and extracted by dilute sulphuric acid represents histone nascent peptides near completion; moreover, the results also indicate that histone nascent peptides on polyribosomes can be acetylated *in vitro*.

The acetyl groups in the histone nascent peptides were characterised by a combination of ion exchange filtration and paper electrophoresis and chromatography. The histone nascent peptides from polyribosomes acetylated *in vitro* and *in vivo* were digested with trypsin, pronase and carboxypeptidase[9]. The resulting solution of acetyl amino acids and peptides was passed through a Dowex 50 H^+ column and the non-absorbed material was eluted with water to obtain the 'acidic' fraction, which contains N-terminal blocked amino acids and peptides. All the absorbed material was eluted with 0.5 N ammonium hydroxide to obtain the 'basic' fraction, containing all the free amino acids and peptides. Radioactivity measurement of these fractions indicates (Table 1) that most of the acetyl groups introduced *in vitro* were associated with the 'acidic' fraction and therefore represent N-terminal acetylation. Only 13% of the acetyl groups attached *in vivo* were found in the 'acidic' fraction. We also tried to identify the N-acetyl amino acids in the 'acidic' fractions. Analysis by paper chromatography (Fig. 3*A*) showed that most of the acetylated material has the same R_F as the standard N-acetylserine (10 cm). Analysis in paper electrophoresis (Fig. 3*B*) also shows the same mobility for the standard acetylserine and the acetyl amino acids in the 'acidic' fraction derived from the nascent peptides acetylated *in vitro*.

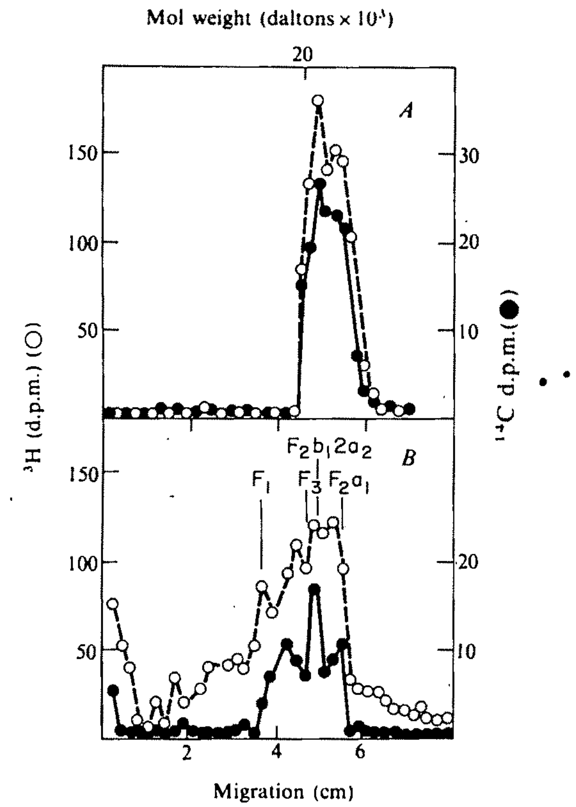

Fig. 2 Electrophoresis of histone nascent peptides extracted from acetylated polyribosomes. Nascent peptides were released with puromycin[4] from polyribosomes acetylated *in vivo* and *in vitro*. Histone nascent peptides were extracted from the puromycin supernatants as described in the text. Samples of 100–200 µg of the dried material containing histone nascent peptides were resuspended in 1 N acetic acid, 10 N urea and 1% mercaptoethanol, and analysed by (*A*) sodium dodecyl sulphate-acrylamide gel electrophoresis as described in Fig. 1, or (*B*) urea-acrylamide gel electrophoresis at *p*H 2.5 (ref. 11). Symbols are as in Fig. 1. Histone standards were also run in parallel and were located by scanning the gels at wavelengths 280 nm, 600 nm, after staining with Coomassie blue[6].

Table 1 Dowex 50 H^+ Fractionation of ^3H-^{14}C-Acetyl Peptides from Histones Extracted from Polysomes of Hepatectomised Rats*

Fraction	^3H d.p.m.	%	^{14}C d.p.m.	%
'Acidic' (N-terminal blocked)	720	13	1,470	96
'Basic' (N-terminal free)	4,470	85	57	5

* Histone nascent peptides (about 1.5 mg) extracted from polyribosomes acetylated *in vivo* and *in vitro* were resuspended in 2 ml of 0.1 M sodium bicarbonate, *p*H 8. Enzymatic digestion with trypsin, pronase and carboxypeptidase A and B was performed as described[9]. After removal of any cold trichloroacetic acid (TCA)-insoluble material by centrifugation and extraction of TCA from the supernatants with ether, the digests were dried under vacuum, resuspended in 2 ml of water and absorbed onto 1 × 8 cm Dowex 50 H^+ columns. The columns were washed with 20 ml of water followed by 20 ml of 0.5 N ammonium hydroxide to obtain 'acidic' and 'basic' fractions respectively. The radioactivity in duplicate 0.2 ml aliquots from the fraction was measured by liquid scintillation counting with 10 ml of Scintisol (Isolab).

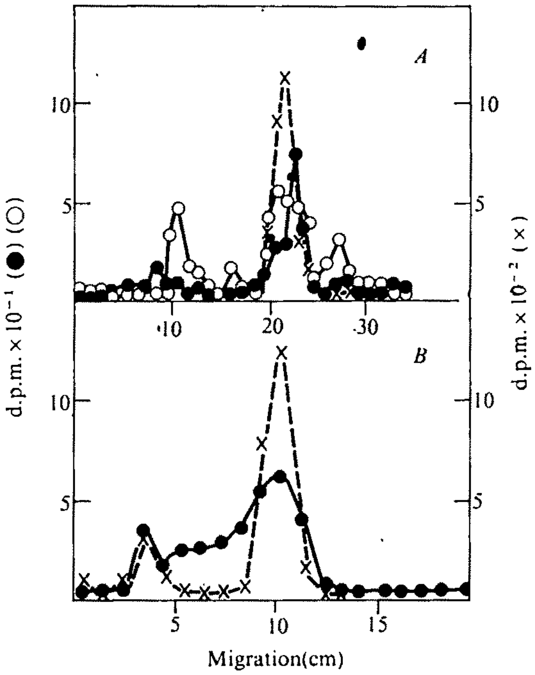

Fig. 3 Chromatographic and electrophoretic characterisation of acetyl peptides in the enzymatic digests. The water eluates from Dowex 50 H^+ columns (see Table 1) were flash evaporated and the residue resuspended in a small volume of water. Aliquots (10 µl) were analysed by (*A*) paper chromatography developed with *n*-butanol : acetic acid : water (12 : 3 : 5) and (*B*) paper electrophoresis[12]. Standard N-^3H-acetylserine was prepared[13] and included in each analysis. Paper strips (1 cm) were eluted with 1 ml of water for 1 h in counting vials, and the radioactivity was measured in a liquid scintillation counter with 10 ml of Scintisol. Solid circles and open circles represent values of nascent peptides labelled *in vitro* ^{14}C and *in vivo* ^3H, respectively. X represents N-^3H-acetylserine standard.

The experiments described here demonstrate that histone-like nascent peptides can be acetylated *in vitro* on polyribosomes from regenerating rat liver. They also show that most of the acetyl groups are attached to N-terminal amino acids, in particular to the amino group of serine. These observations can account for the *in vivo* acetylation of nascent peptides in polyribosomes from regenerating rat liver and provide direct evidence for a mechanism that can explain the presence of N-terminal acetyl groups in liver proteins, without the necessary involvement of N-acetylation during the initiation of protein synthesis[5]. The acetyltransferase activity found in rat liver ribosomes[6,9] may be the enzyme involved in the N-terminal acetylation of nascent peptides observed in this study. Since relatively few proteins are known to have N-acetyl termini, this enzyme must have a relatively high specificity. Further studies will be required to define this specificity in terms of the terminal sequence and the minimal size of the peptide substrate. Enzyme activities able to acetylate haemoglobin[14] or histone[15] have been found in ribosome-free reticulocyte lysates and rat liver postmicrosomal supernatants respectively. To what extent these activities are functionally involved in the N-terminal acetylation of proteins deserves further study.

Spontaneous Re-formation of a Broken Peptide Chain

BASIC pancreatic trypsin inhibitor (BPTI) is a protein of fifty-eight amino acid residues, which inhibits the serine proteinases trypsin, chymotrypsin, plasmin and kallikrein. The sequence has been fully elucidated[1] (Fig. 1) and the three-dimensional structure has been determined to high resolution by X-ray crystallography[2,3]. In connection with studies on the partial synthesis of analogues of BPTI for the investigation of protein folding, we have examined in detail cleavage of the protein by cyanogen bromide[4]. We have found that the chain-cleaved product is unstable, and that on standing it is spontaneously transformed into an analogue of BPTI containing an intact chain of fifty-eight amino acid residues.

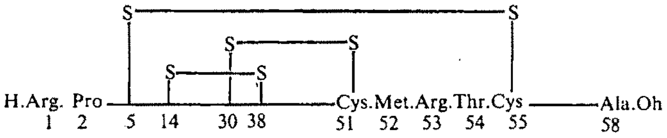

Fig. 1 BPTI part structure.

The single methionine residue in BPTI occurs at position 52 of the peptide chain. The crystal structure indicates that it is approximately in the middle of the only extended region of α-helix, and lies near the surface of the tightly folded molecule. Chemical evidence[5] indicates that the methionyl side chain is accessible to some, but not all, modifying reagents when the molecule is in its native conformation. There are also six cysteinyl residues in BPTI, which form three disulphide bridges. Two of these residues also occur in the α-helical region, at positions 51 and 55, straddling the position of the methionine residue. Thus, when the peptide chain of the native molecule has been broken with conversion of the methionine to homoserine lactone by cyanogen bromide, the resulting two backbone fragments are still held together by a disulphide linkage (between residues 5 and 55). As we shall demonstrate, this covalent bond between the fragments promotes the resynthesis of a peptide bond between residues 52 and 53 by attack of the newly generated amino terminus on the lactone carbonyl.

Treatment of BPTI with a hundred-fold excess of cyanogen bromide caused conversion of methionine to homoserine in 80% of the molecules within 20 h. Only one of the various expected products of cyanogen bromide treatment, the species in which chain cleavage between residues 52 and 53 has occurred and in which the homoserine residue is in the lactone form, should differ in net charge at neutral *p*H from BPTI. Accordingly ion-exchange chromatography of the cyanogen bromide-treated protein resolved two major peaks (Fig. 2). The first peak emerged at the same position as native BPTI; amino acid analysis of this material indicated that it contained all of the molecules with residual methionine. The second peak contained protein (II) in which the peptide chain has been broken. No methionine could be detected in this product, but acidic hydrolysates which had been heated in pyridine acetate just before analysis[8] contained 1.0 residue of homoserine per protein molecule. Furthermore, the new N-terminus, arginine 53, could be released in high yield by digestion of II with leucine aminopeptidase[9]. Although the normal N terminus of native BPTI is also arginine, this residue is not released by leucine aminopeptidase, presumably because residue 2 of the protein is proline.

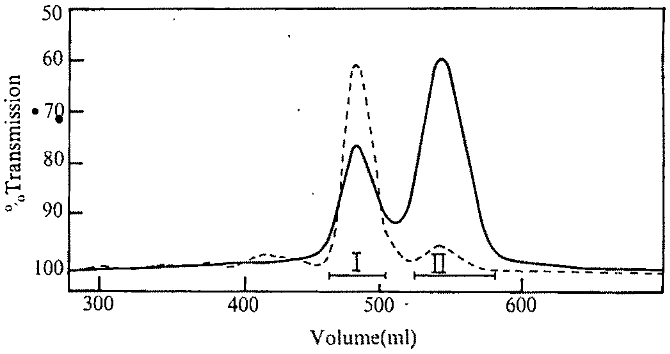

Fig. 2 (——), Ion-exchange chromatogram on a 1.3 × 30 cm column of carboxymethylcellulose (CM-52) of the desalted product from treatment of native BPTI with a hundred-fold excess of CNBr in 70% formic acid. The protein was chromatographed at *p*H 6.2 in 0.01 M phosphate buffer using a linear gradient of NaCl[6,7] (0–0.5 M, 400 ml in each chamber.) The position of peak I is identical to that obtained for native BPTI. Peak II corresponds to a more positive species. (- - -), Rechromatography of a sample of II after 6 d at *p*H 6.5.

Tryptic maps of II also definitely established backbone cleavage. When BPTI was reduced and carboxymethylated with ^{14}C-labelled iodoacetic acid, the resulting product was readily digested by trypsin[10,11], and electrophoresis at *p*H 6.5 resolved the four radiolabelled peptides (Fig. 3*a*). Two of these contained two carboxymethylcysteine residues each: peptide 1–15 (including cysteine residues 5 and 14) and peptide 27–39 (including cysteine residues 30 and 38). The other two peptides, 47–53 and 54–58, contained only one radiolabelled residue each, numbers 51 and 55, respectively. When II was reduced and carboxymethylated in the same manner, the hexapeptide 53–58 was removed upon desalting through Sephadex G25. Tryptic digestion of the large protein product and subsequent electrophoresis showed that the normal peptides 47–53 and 54–58 were virtually absent, while a new, more acidic peptide was present (Fig. 3*b*). This new peptide had an amino acid composition consistent with sequence 47–52 (52 = homoserine).

The properties of II have been observed to change with time in a manner which indicates resynthesis of the peptide backbone. This process has been primarily studied through the tryptic peptides of ^{14}C-carboxymethylated material. These studies were made quantitative by adding uniformly ^{3}H-carboxymethylated BPTI to samples before digestion, to act as an internal control. The ratio of ^{14}C to ^{3}H in the peptides 47–53 and 54–58 relative to that in the peptides 1–15 and 27–39 indicates the fraction of material in which the 52–53 peptide bond has been re-formed. For preparations of II in which the ion-exchange chromatography was performed at room temperature and the products were left at *p*H ~6.2 for a few hours, the amount of resynthesised protein varied from 15 to 35%. When chromatography was performed at 4° C and the products were trapped at approximately *p*H 3 by precharging each fraction with a small amount of acetic acid, the concentrations of peptides 47–53 and 54–58 detected could be kept to 5%.

The observations above are fully consistent with spontaneous resynthesis of the peptide chain in neutral solutions, and we have been able to follow the course of the resynthesis reaction with this radiolabelling procedure. A solution of II kept at *p*H 6.3 was sampled over the course of 2 d, and the described mapping procedure was employed at each stage. There was a progressive increase in the relative proportion of the peptides 47–53 and 54–58 and a corresponding attenuation in the amount of peptide 47–52 detected in successive samples, thereby indicating clearly the reconstitution of the protein backbone with time. Quantitative analysis of these successive samples by the method of double-counting outlined previously indicated an initial half-life for the resynthesis reaction of about 30 h. Similar analysis of a sample of II which had been reduced and carboxymethylated after standing 4 d at *p*H 6.3 (Fig. 3*c*) indicated the presence of peptides 47–53 and 54–58 in at least 85% yield and only a small amount of peptide 47–52. When the product obtained from such a resynthesis reaction was rechromatographed on the ion-exchange column used to isolate II, the majority of the material emerged in the position corresponding to BPTI (Fig. 2).

Neutral solutions of II also gained in inhibitory potency as a function of time. Preparations of II were found to be only 50% as potent as native BPTI in inhibiting trypsin (as determined by the benzoylarginine *p*-nitroanilide assay)[12] and 30% to 50% as potent in inhibiting chymotrypsin (as determined by the acetyltryptophan ethyl ester assay)[13]. In both cases the rate of increase towards the level of activity of BPTI agreed well with the rate of resynthesis demonstrated by the radiolabelling experiments.

The resynthesised protein, [52-homoserine]-BPTI, has been found to possess between 85% and 95% of the inhibitory potency of BPTI towards both trypsin and chymotrypsin. Furthermore, in the acetyltryptophan ethyl ester assay, in which BPTI is slowly displaced from chymotrypsin by the substrate, solutions of [52-homoserine]-BPTI of equal initial inhibitory potency exhibited a rate of inhibitor displacement indistinguishable from that for BPTI. The binding constants to chymotrypsin for both molecules must therefore be virtually identical. This is not surprising, as residue 52 is far removed from the active site of the molecule[11], and oxidation of methionine-52 has previously been shown not to alter its inhibitory properties[5].

Experiments involving reduction of the disulphide bridges and their subsequent reoxidation also demonstrated the resynthesis of the protein backbone in II. Native BPTI, which had been fully reduced in strong denaturing agents, could be reoxidised in neutral *p*H buffers by air or disulphide reagents with full regain of inhibitory activity. This was not true of II, which after reduction would regain activity only to the extent to which there was resynthesised material present. Nor would such samples regain activity beyond the level indicated when a ten-fold excess of the cleaved hexapeptide was added to the oxidising solution. Purified samples of [52-homoserine]-BPTI, however, were readily reoxidised to a fully active state after reduction. The rate of reoxidation of reduced [52-homoserine]-BPTI by disulphide reagents, measured as its rate in regaining potency as a trypsin inhibitor, was comparable to that measured simultaneously for reduced BPTI.

Our discovery of an example of facile resynthesis of a peptide backbone in a cyanogen bromide-cleaved protein indicates that this may be a practical route to the partial synthesis of some protein analogues. The direct coupling of lactone and amino components under favourable circumstances, as in this case where the fragments are held close together by a disulphide bridge, may provide routes for partial synthesis complementary to those already suggested employing such lactone functions[15], but which require more lengthy synthetic routes. We are at present exploring methods of utilising this more direct resynthesis reaction *en route* to new analogues of BPTI.

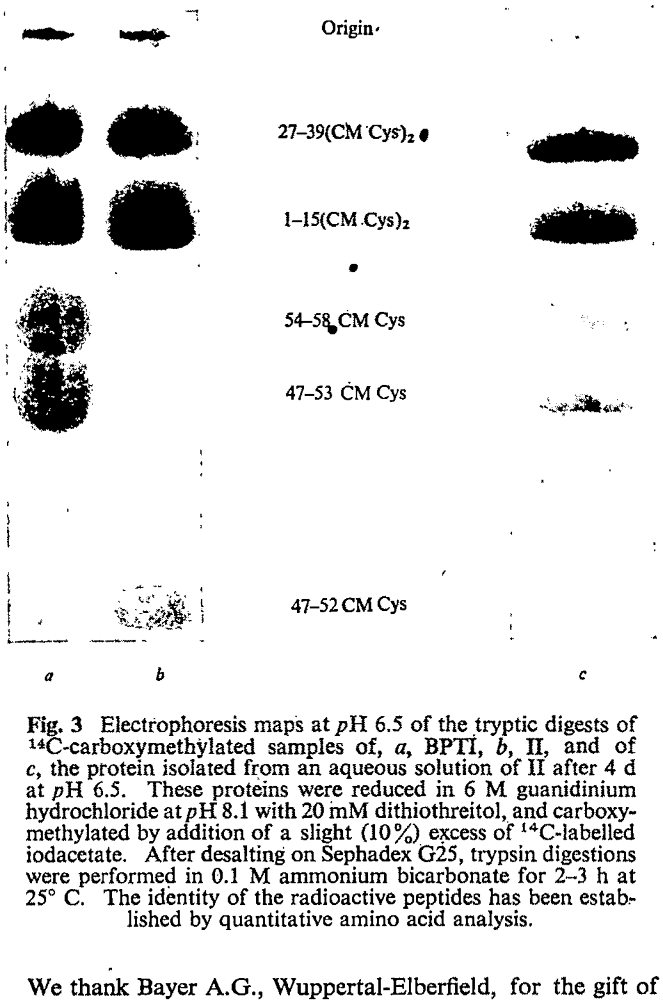

Fig. 3 Electrophoresis maps at *p*H 6.5 of the tryptic digests of ^{14}C-carboxymethylated samples of, *a*, BPTI, *b*, II, and of *c*, the protein isolated from an aqueous solution of II after 4 d at *p*H 6.5. These proteins were reduced in 6 M guanidinium hydrochloride at *p*H 8.1 with 20 mM dithiothreitol, and carboxymethylated by addition of a slight (10%) excess of ^{14}C-labelled iodacetate. After desalting on Sephadex G25, trypsin digestions were performed in 0.1 M ammonium bicarbonate for 2–3 h at 25° C. The identity of the radioactive peptides has been established by quantitative amino acid analysis.

We thank Bayer A.G., Wuppertal-Elberfield, for the gift of BPTI (Trasylol ®).

Structure and Conformation of a Cyclic Tripeptide

MANY cyclic peptides have interesting biological functions and the details of their molecular structure and conformation have been the subject of extensive investigations. Cyclic dipeptides such as diketopiperazine have been synthesised and shown to occur with the peptide units in the *cis* configuration[1,2]. In the case of a tripeptide, cyclisation can take place only if all three units are in the *cis* configuration[3]. In cyclic peptides with four units also, *cis* peptides are found[4,5]. As the number of the peptide units increases, the more stable *trans* configuration is generally more common[6,7]. We report here the main results of our X-ray crystallographic investigations of the cyclic tripeptides L-Pro-L-Pro-L-Pro and L-Pro-L-Pro-L-Hyp (hereafter called CTP 1 and CTP 2, respectively). CTP 1 was synthesised by Rothe *et al.*[8] and its derivatives have been prepared by Blout and his collaborators[9].

Venkatachalam[3] predicted that in the cyclic tripeptide CTP 1 all three peptides should be in the *cis* configuration for ring closure to be achieved. In his study, however, the conformational parameters were worked out on the assumption that the proline rings and the nitrogen environment are essentially planar. Nuclear magnetic resonance (NMR) studies on cyclic peptide derivatives have shown that the peptide units are indeed *cis* planar, but the proline rings are non-planar with the nitrogen atom out of the mean plane through the remaining four atoms of the proline ring[9]. Our studies show that the peptide units are *cis* planar in general, but the conformation of the proline rings is somewhat different from that reported in the NMR studies.

Crystals of CTP 1 and CTP 2 were recrystallised from material given to us by Professor E. R. Blout of Harvard Medical School. The crystal data are shown in Table 1. The diffraction data were collected manually on a GE XRD-3 diffractometer to a limit of $2\theta = 150°$. These two acentric structures, with 42 and 22 non-hydrogen atoms respectively in the asymmetric units, were solved by the direct methods using the MULTAN program[10], and refined by the block diagonal least squares method. During the refinement of CTP 2, it became apparent that the hydroxyl group was disordered. The electron density difference map showed two positions OH (1) and OH (2) for the hydroxyl group, the relative occupancy of OH (2) being twice the other. It is interesting that, for both these sites, the OH group is linked by a strong hydrogen bond (2.7 Å) to the carbonyl oxygen of a neighbouring molecule. All the hydrogen positions in the molecule of CTP 2 were established from the electron density difference map. The diffraction data from CTP 1 were of poor quality, and consequently unambiguous location of the hydrogen atoms was not possible in this case. A view of the molecule of the tripeptide as it occurs in the crystal structure of CTP 2 is shown in Fig. 1.

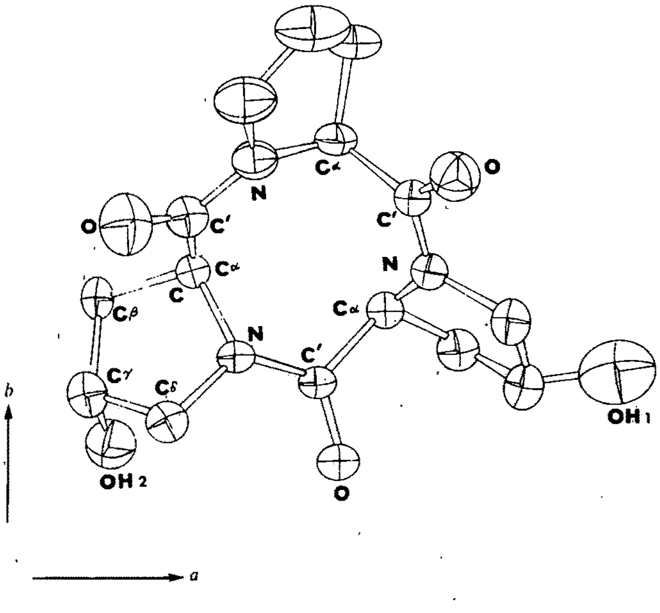

Fig. 1 View of the tripeptide molecule in CTP 2 looking down the *c* axis[13].

Table 1 Crystal Data of CTP 1 and CTP 2

	CTP 1	CTP 2
a	15.95 Å	16.28 Å
b	19.09 Å	9.45 Å
c	9.23 Å	9.23 Å
z	8	4
Space group	$P\,2_12_12_1$	$P\,2_12_12_1$
λ	1.5418 Å	1.5418 Å
Number of measured reflections	3,299	1,762
Percentage used for electron density calculation	79	97
Reliability index	0.13	0.06

The orientation of the tripeptide molecules in the structures of CTP 1 and CTP 2 is very similar when viewed down the *c* axis. The two molecules (*A* and *B*) in the asymmetric unit of CTP 1 are inclined to each other by about 55°. The average torsion angle $\chi_1(\text{N-C}_\alpha\text{-C}_\beta\text{-C}_\gamma)$ for the eight residues was 31°, in good agreement with the value obtained from NMR data[9]. The puckering of the different proline residues in the three tripeptide molecules is given in Table 2. The average value of the torsion angle $\omega(\text{C}_2\text{-C}'\text{-N-C}_2)$ is 1.8° for eight of the nine residues, while in the hydroxyproline residue it is as high as 19°. These torsion angles showed a fairly wide spread of about 5°. Therefore it seems that the cyclisation of three peptides could be achieved without invoking any excessive non-planarity of the peptide group. The backbone dihedral angles ϕ and ψ range from $-94°$ to $-110°$ and 83° to 98° respectively. These are appreciably different from the values $-78°$ and 109° predicted earlier[3]. Because of these variations in the torsion angles, from peptide to peptide in the tripeptide molecule, the backbone conformation in the crystal does not possess a true three-fold symmetry, assumed in interpreting the results of the solution studies[9]. Thus, we find many new types of conformation for the proline rings here different from any of those reported before in X-ray and NMR studies[11].

We have averaged the latest data from eight crystallographically independent *cis* proline residues in the crystals of CTP 1 and CTP 2 and obtained the dimensions of the standard *cis* proline residue (Fig. 2). The average ring torsion angles $\chi_1(\text{N-C}_\alpha\text{-C}_\beta\text{-C}_\gamma)$, $\chi_2(\text{C}_\alpha\text{-C}_\beta\text{-C}_\gamma\text{-C}_\delta)$, $\chi_3(\text{C}_\alpha\text{-C}_\beta\text{-C}_\delta\text{-N})$, $\chi_4(\text{C}_\gamma\text{-C}_\delta\text{-}$

Table 2 Puckering of Proline Residues in the Three Tripeptide Molecules

Atom out of plane	No. of residues CTP 1(*A*)	CTP 1(*B*)	CTP 2
C_α	1	—	1
C_β	2	3	1
N	—	—	1

N-C_α) are also shown in Fig. 2. It is worth noting that in CTP 1 and CTP 2 the C′-N bond distance (1.362±0.015 Å) is significantly larger than the value (1.32 Å) found in the *trans* peptide unit postulated by Corey and Pauling[12]. The average parameters we have obtained agree with the values reported by Karle[2].

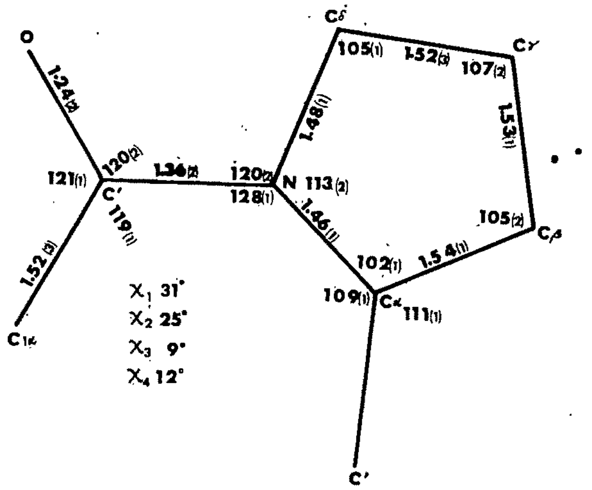

Fig. 2 Dimensions of the standard *cis* proline residue averaged from eight independent residues in CTP 1 and CTP 2. The RMS deviation in the dimensions in the eight residues is also indicated.

Interferonogenicity and Antigen Recognition

NOT only viral and syngeneic polynucleotides but also bacterial endotoxins, PHA (refs 1 and 2), heterologous and, in certain cases, homologous gammaglobulins can induce interferon[3-5]. The question arises whether or not antigenicity correlates with interferonogenic properties. We therefore studied the interferonogenic properties of syngeneic and allogeneic living or irradiated mouse spleen cells (SC), xenogeneic and allogeneic erythrocytes and syngeneic materials (erythrocytes and sera) that had become autoantigenic after treatment with trypsin, iodination or heating.

SC were obtained from aseptically removed mouse spleens by soft compression in the glass Potter homogeniser. The cells were twice washed with medium 199 by centrifuging at 2,000 r.p.m. for 15 min, and the number of living nucleated cells was counted. Iodinated serum proteins were prepared according to Wormall[6]. The activity of serum interferon

	C57Bl/6j	SC–DBA/2	17	40
	C57Bl/6j	ISC–DBA/2	4	5
	C57Bl/6j	ISC–DBA/2	17	30

* SC exposed to gamma-irradiation, total dose 16,000 r, and mice recipients C57Bl/6j (in experiment 3), in a dose (total) of 850 r.

† Unit of interferon activity is a reciprocal of the endpoint serum interferon dilution inhibiting cytopathic effect.

was evaluated by a standard method[7]: 1 ml of the corresponding dilution of the serum to be studied (interferon) was placed on 48 h cultures of mouse L cells in each tube. The serum was removed 18–24 h later and 100 tissue culture pathogenic dose 50% ($TCPD_{50}$) of vesicular stomatitis virus were added and 24 h later the highest dilution of interferon that inhibits the cytopathic effect by 50% was determined. The tested dilutions of mouse sera higher than 1 : 20 were not toxic to L cells. In each experiment the interferon was titrated repeatedly two or three times. Mice of the strains Balb/c, DBA/2, C57Bl/6j and hybrids F_1 (CBA×C57Bl/6j) were used. Groups of fifteen to twenty-five mice recipients were inoculated with the following antigens: 10^8 of SC in 0.8 ml of medium 199, 6×10^9 erythrocytes in 0.5 ml of medium 199 and sera treated in different ways, in a volume of 0.5 ml. At different times (from 3 to 48 h) after antigen injection blood was taken from the mouse retro-orbital sinus and interferon was determined in the serum.

Intravenous injection of allogeneic SC leads to a marked interferon production in mice (Table 1). The maximum interferon concentration in the serum of mice recipients was observed 12–24 h after SC injection. Such interferon production takes place even in cases in which a donor and a recipient differ from each other in weak histocompatibility loci: mouse strains DBA/2 and Balb/c (experiment 1, Table 1). An intravenous injection of syngeneic SC does not lead to interferonogenesis. From experiments 2 and 3 with F_1 hybrids and with irradiated SC and/or irradiated recipients (see Table 1), it is evident that both donor and recipient lymphoid cells produce interferon.

Table 2 Interferon Activity after Injection into Mice of Normal and Trypsin-treated Red Blood Cells (RBC) and Iodinated and Heated Sera

Experiment No.	Recipient mice	Material injected	Time after injection (h) 6	12	24
5	C57Bl/6j	RBC–C57Bl/6j	0	0	0
	C57Bl/6j	RBC–Balb/c	5	5	5
6	DBA/2	RBC–Balb/c	—	0	—
	DBA/2	RBC–DBA/2	—	0	—
7	C57Bl/6j	RBC–sheep	5	5	5
	C57Bl/6j	Trypsin-treated RBC–C57Bl/6j	5	10	20
	C57Bl/6j	C57Bl/6j serum	—	—	0
	F_1(CBA × C57Bl/6j)	Syngeneic serum	—	0	—
	F_1(CBA × C57Bl/6j)	Iodinated syngeneic serum	—	20	—
	F_1(CBA × C57Bl/6j)	Syngeneic serum heated at 56°	—	5	—

This serum interferon was stable at 24 h at *p*H 2, lost antiviral activity in the presence of 0.1% of trypsin at 37° C for 1 h, failed to sediment at 100,000*g* for 1 h, did not lose activity when cultures treated with the serum interferon were washed before virus challenge, was active in mouse L cells against Venezuelan equine encephalitis virus and Sindbis virus, and did not possess any antiviral properties in the continuous cell culture of human amniotic F1 cells.

Allogeneic and xenogeneic erythrocytes induce only slight interferon production. Non-interferonogenic syngeneic erythrocytes acquire interferonogenic activity when treated with trypsin (Table 2). Syngeneic mouse serum is non-interferonogenic. The same serum becomes interferonogenic after heating or iodination.

In this laboratory the role of interferon in lymphocyte-target cell interaction has been established[8–11]. Interferon induces the sensitivity of target cells to the cytotoxic effects of normal allogeneic lymphocytes[12]. Other data on the connection of immune response and interferonogenesis have accumulated. Lymphoid cells were established as the main interferon producers *in vivo*[1,2]. A variety of agents suppressed antibody formation and interferon production in parallel[1]. Green *et al.*[13] suggested that immune recognition mechanisms are involved in enhanced interferon production in secondary immune response to non-viral antigens.

The experimental evidence presented above shows that cells and substances immunologically recognisable as 'self' do not induce interferon production and conversely cells and substances recognisable as 'non-self' do induce interferonogenesis after primary administration. The quantities of interferon produced after injection of various antigens were different. We suggest that antigen induces interferon production in cells involved in the first stage of the immune response.

Spontaneous Fusion of Rat Liver Lysosomes *in vitro*

THE fusion of membranes is a key to the control of lysosomal function. Membrane fusion is involved in both the intra- and extracellular digestion of extracellular material (fusion between endocytotic vacuoles or between plasma membrane and enzyme-bearing vesicles) as well as in the formation of autophagic vacuoles. Primary lysosomes fuse readily with newly formed endocytotic vacuoles[1,2]; they seem to be able to fuse with heterolysosomes[3] but never directly with mitochondria or nuclei. Because of scanty information the apparent specificity in the fusion pattern of primary lysosomes cannot be explained in terms of relationships between membrane composition and function. Dingle[4] has proposed, in analogy to the coalescence of closed shells of fluid, or the 'breaking' of an emulsion by agglomeration of droplets to larger ones, that the fusion of cell membranes of high surface tension will be thermodynamically favoured. According to this suggestion lysosomes should be regarded as high surface tension vesicles.

The above considerations prompted us to investigate the possibility of spontaneous fusion of a lysosomal population *in vitro*. Lysosome-rich suspensions were incubated at 0° C and at 37° C for time intervals extending up to 3.5 h. At zero time, 0.5, 1 and 3.5 h the suspensions were analysed for free and 'available' acid phosphatase activity (Fig. 1), and

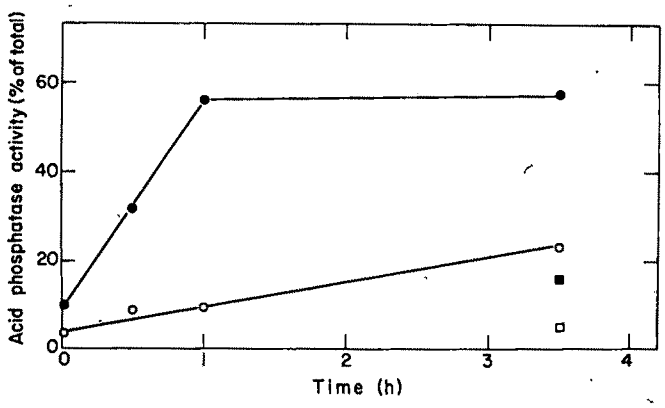

Fig. 1 Time dependence of free (○—○) and available (●—●) acid phosphatase activity in lysosomal suspensions incubated at 37° C. Corresponding values obtained in lysosomal suspensions incubated for 3.5 h at 0° C are also included (□, ■). Incubation mixture consisted of 23.5 mg of lysosomal protein ml^{-1} isolated as described[13], 0.25 M sucrose and 0.01 M Na-HEPES, *p*H 7. At the specified time intervals, 20 µl aliquots were removed from the suspensions and assayed[14] with *p*-nitrophenyl phosphate for free activity (detected in the medium after sedimentation of lysosomes), available activity (exhibited by the whole suspension), and total activity (reaction mixture made 0.1% in Triton X-100).

were fixed for electron microscopic examination. Continuous slow release of acid phosphatase to the medium was observed in lysosomal suspensions incubated at 37° C (20% in 3.5 h); no such release was observed in suspensions incubated at zero degrees. The latency of acid phosphatase activity was, however, markedly affected during incubation at 37° C. After about 1 h of incubation the available acid phosphatase activity of lysosomal suspensions increased from a value of 10% to about 60% of the total activity. The lysosomal membranes thus seem to have undergone a change in their barrier properties towards *p*-nitrophenyl phosphate, a substrate for acid phosphatase. No such change was observed in suspensions incubated at 0° C.

Electron micrographs of zero time suspensions showed populations of vesicles mostly regular in shape: spherical or ellipsoid. Some of the vesicles were more phosphotungstic acid positive, others were stained only in the limiting membrane and its close periphery (Fig. 2*a*). The same pattern was obtained in a histochemical assay of acid phosphatase (Fig. 2*b*). The dramatic change in both the dimensions and the shape of the suspended vesicles as a result of a 3.5 h incubation period at 37° C is shown in Fig. 2*c*. The average diameter of lysosomes incubated for 3.5 h at 37° C was twice that obtained for zero time control lysosomes (~0.5 µm). This indicates roughly at least a four-fold increase in vesicular surface area. Figure 2*d* shows lysosomes incubated for 3.5 h at zero degrees. It thus seems that the morphological changes are temperature dependent.

It is worth noting that lysosomal suspensions kept at 0° C (Fig. 2*a* and *d*) contain a significant percentage of mitochondria. No mitochondria could be detected in pellets of lysosomes incubated for 3.5 h at 37° C; suggesting mitochondrial breakdown, possibly due to the presence of free lysosomal enzymes in the medium.

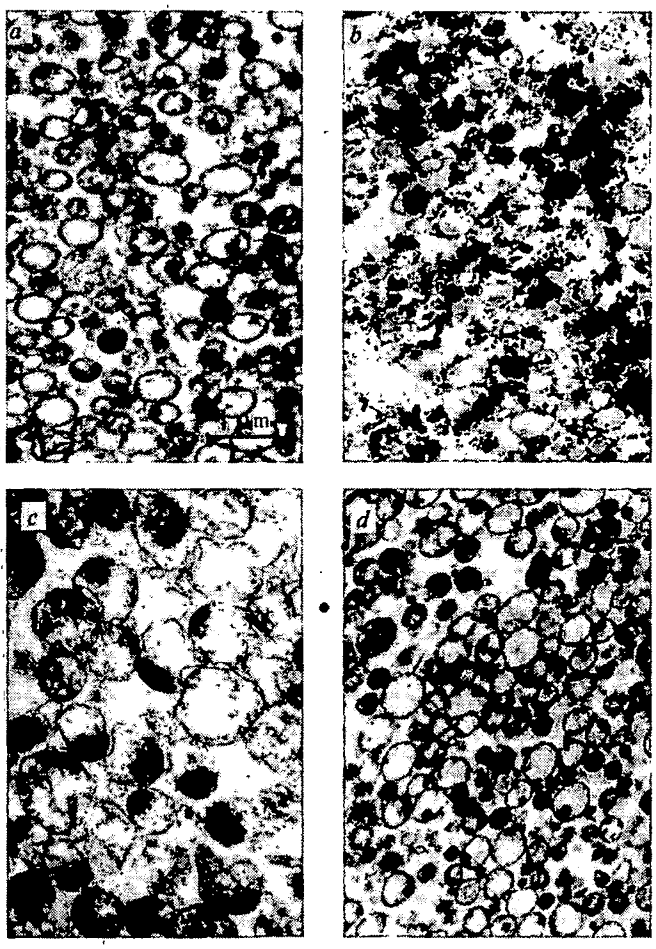

Fig. 2 Characteristic morphology of lysosome-rich suspensions, ×8,530. *a*, Zero time suspension; *b*, zero time suspension stained histochemically for acid phosphatase[15]; *c* and *d*, lysosomal suspensions incubated for 3.5 h at 37° C and at 0° C, respectively. Incubation of the lysosomal suspensions (described in Fig. 1) was terminated by centrifugation. The lysosomal pellets were resuspended in 0.1 M Na-cacodylate, *p*H 7.4, containing 2% of glutaraldehyde. After 1 h of fixation the pellets were washed, and post-fixed for 1 h with 1% osmium tetroxide. The resulting precipitate was dehydrated and embedded in epoxy resin according to Spurr[16]. Thin sections obtained with Sorvall, Porter-Blum MT 2-B ultra-microtome were stained for 30 s with 1% phosphotungstic acid in 70% ethyl alcohol, and were analysed in a Phillips 300 electron microscope.

The enlargement of vesicular contours could be brought about either by intralysosomal degradation of macromolecules, leading to an increase in osmotic pressure and lysosomal swelling or by fusion of vesicles. The first mechanism would imply that the lysosomal membrane has an unusual expanding capacity, since lysosomes are not endowed with biosynthetic capacity. Measurements of membrane thickness in both 0° C control and 37° C incubated lysosomes do not support such a mechanism. Fusion of vesicles during the incubation period at 37° C is the most plausible explanation for the morphological transformation of the lysosomal suspension. Since 3.5 h incubation yielded a rather homogeneous population of enlarged vesicles, it could be reasoned that on shorter incubation intermediate steps in the fusion process could be arrested. Figure 3 shows such intermediate steps. Note the small protrusions which develop at areas of close contact between lysosomes (Fig. 3*a* and *b*). It would seem reasonable that these protrusions facilitate the interdigitation of membrane elements of two vesicles. A latter step involving membrane fusion would establish permanent connections between vesicles. The resulting structures seem to be closed vesicles encompassed by an intact membrane. Phosphotungstic acid positive material tends to aggregate at one pole of the vesicles (Fig. 2*c*). As previously pointed out the observed two-fold increase in particle diameter indicates for a sphere a four-fold increase in surface area and an eight-fold increase in volume. If it is assumed that the total membrane area is constant and that intralysosomal volume is preserved (no swelling following fusion), then it is to be expected that the vesicles resulting from lysosomal fusion would not be spheres. This indeed seems to be the case (see Fig. 2*c*). The continuous release of acid phosphatase to the suspending medium (Fig. 1) suggests that some lysis accompanies lysosomal fusion. Such a process has been proposed as a prerequisite to chemical[5,6] and viral[7] induced fusion of cells.

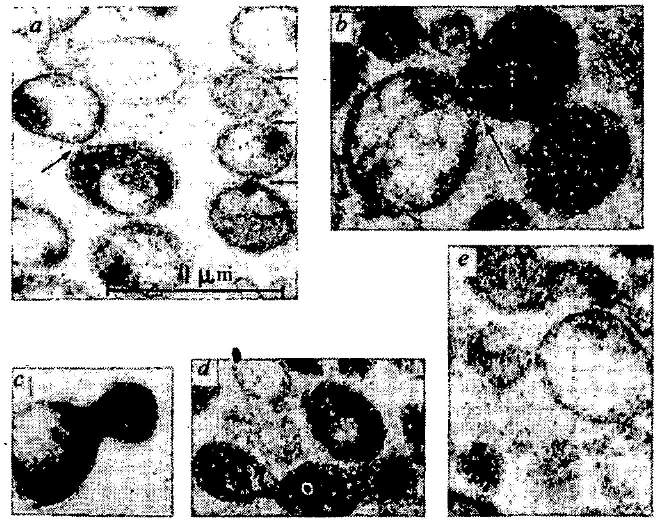

Fig. 3 Intermediate steps in lysosome fusion. Lysosomal suspensions (details in legend to Fig. 1) were incubated for 0.5 h (*a* and *c*) and for 1 h (*b*, *d*, *e*) at 37° C. Incubation was terminated by centrifugation and the pellets processed as described for Fig. 2. *a*, ×22,500; *b*, *c*, ×67,500; *d*, *e*, ×29,160.

The observed temperature dependence of fusion could be attributed to the involvement of enzyme action, though chemically induced cell fusion[8] has also been shown to be markedly temperature dependent.

The molecular events preceding fusion are not yet understood. It seems, however, that extraorganelle energy sources or bivalent cations are not essential elements in the process. It has been suggested[9] that a primary requirement for the fusion of two biological membranes is that both membranes involved have a relatively high proportion of their phospholipid molecules in the micellar configuration. It was also argued that molecules like lysolecithin, found in lysosomal membrane phospholipids[4], can induce micellar configuration[9]. Moreover, the presence of phospholipases in lysosomes which could degrade lecithin to lysolecithin has been reported[10,11].

Similar morphological changes, that is, the appearance of protrusions leading to bridge formation, have been reported in the case of fusion of rat parotid secretory granules with the cell membrane at the lumen[12] and in chemically induced fusion of avian erythrocytes[5].

We thank Dr V. Bengiate for acquainting us with electron microscope techniques.

Selective Binding Properties of Vitamin D Transport Protein in Chick Plasma *in vitro*

WHILE vitamin D$_2$ and vitamin D$_3$ are equipotent antirachitic agents in most mammals[1] ergocalciferol (D$_2$) is approximately 1/100 as potent as cholecalciferol (D$_3$) in preventing or curing rickets in young chicks[2]. Although the basis of the insensitivity in chicks to D$_2$ has not yet been elucidated, it had been noted that radioactive vitamin D$_2$ is cleared from blood more rapidly than radioactive D$_3$ while inactive metabolites of D$_2$ are excreted more rapidly in the bile and faeces[3]. We have shown that a specific transport protein for vitamin D and D metabolites exists in the plasma of D-deficient chicks as well as in the plasma of several mammalian species[4]. These specific transport proteins serve to solubilise vitamin D compounds in the aqueous environment of plasma and to protect the steroids from oxidative inactivation[5]. Since vitamin D requires efficient plasma transport to the liver and the kidney for successive enzymatic hydroxylations[6–8] and the 'activated' metabolites must, in turn, be transported efficiently to the target tissues, we undertook studies to test the hypothesis that the lower potency of D$_2$ might, in part, reflect weaker binding of vitamin D$_2$ and its metabolites to the chick plasma transport protein.

Our approach to this problem involved the use of D$_2$ and D$_3$ analogues to competitively displace ^{3}H-25-OH-D$_3$ from the specific binding protein in plasma from various species[9]. It was necessary to first remove all non-specific binding proteins such as chylomicra, low density and very low density lipoproteins from the plasma through selective precipitation with heparin and manganese chloride[10]. The plasma was then diluted with barbital acetate buffer, *p*H 8.6 (ref. 9), and used in an assay system which included ^{3}H-25-OH-D$_3$ and the vitamin D analogue to be tested. Following a 2 h incubation at 4° C, separation of the unbound ^{3}H-25-OH-D$_3$ from that associated with the specific binding protein was accomplished with dextran-coated charcoal and the ^{3}H in the supernatant was counted in Aquasol (New England Nuclear). Increasing amounts of each analogue tested produced progressive reduction of the ^{3}H-25-OH-D$_3$ in the 'bound' supernatant fraction allowing the development of displacement curves and comparison of the relative binding of the D$_2$ and D$_3$ analogues by the plasma from chick and other species.

In the assay system with rat plasma, increasing amounts of vitamin D$_2$ and D$_3$ produced similar reductions of the ^{3}H-25-OH-D$_3$ in the supernatant fraction (Fig. 1*a*) indicating equivalent binding of D$_2$ and D$_3$ by the rat transport protein. Increasing amounts of 25-OH-D$_2$ and 25-OH-D$_3$ also produced quantitatively equivalent reduction of ^{3}H-25-OH-D$_3$ confirming the equivalent binding of D$_2$ and D$_3$ by the rat binding protein for vitamin D (Fig. 1*b*). Equivalence of binding of D$_2$ and D$_3$ was also found with the transport proteins in human, rabbit, cow, and dog plasma, species in which D$_2$ and D$_3$ are biologically equivalent[1]. In contrast, using the assay

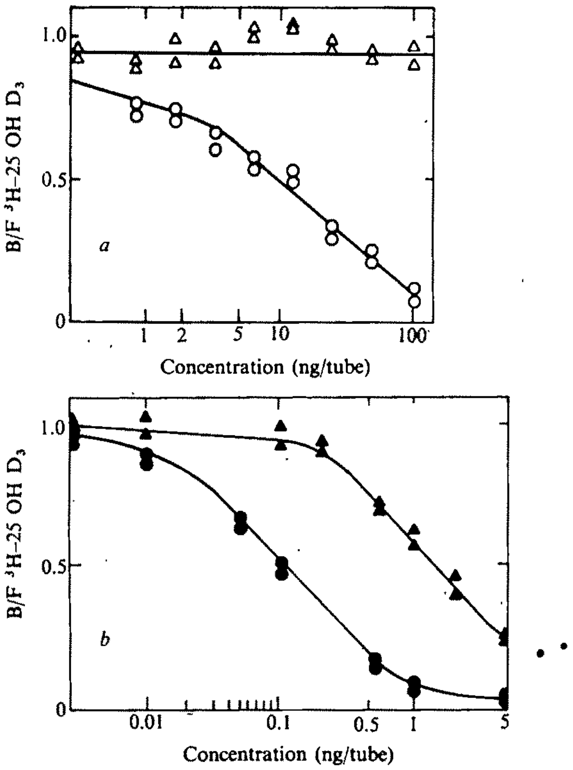

Fig. 1 Displacement of ^{3}H-25-OH-vitamin D_3 from D-deficient rat plasma with vitamin D analogues. Plasma obtained from D-deficient rats was cleared of non-specific binding proteins[10] and diluted with barbital acetate buffer, *p*H 8.6. Increasing amounts of the analogue to be tested with a fixed amount of ^{3}H-25-OH-D_3, all in 95% ethanol, were added to the diluted binding protein (B) or to buffer only (D). An additional aliquot of the analogue with the ^{3}H-25-OH-D_3 was added to a counting vial for determination of the c.p.m. added to each tube (T-total c.p.m.). Separation of unbound ^{3}H-25-OH-D_3 in both B and D tubes was accomplished with dextran-coated charcoal (0.25% Norit A Charcoal and 0.025% Dextran T80). Specific binding was determined by subtracting c.p.m. in the supernatant in the absence of binding protein (D) from the c.p.m. with the binding protein present (B) and the bound/free (B/F) ratio calculated: $B/F = B - D/T - (B-D)$. ○, D_3; △, D_2; ●, 25-OH-D_3; ▲, 25-OH-D_2.

system with chick plasma, increasing amounts of D_2 were ineffective in displacing the ^{3}H-25-OH-D_3 when compared with D_3 (Fig. 2*a*). Tests of displacement of the ^{3}H-25-OH-D_3 by concentrations of D_2 in excess of 100 ng per tube were not possible due to the limited solubility of the fat-soluble vitamin in the aqueous medium of the assay system. 25-OH-D_2 was less efficient than 25-OH-D_3 in displacing the ^{3}H-25-OH-D_3 from the chick transport protein (Fig. 2*b*); fifteen times more 25-OH-D_2 than 25-OH-D_3 (w/w) was required to produce 50% displacement. Similar results, that is, marked reduced binding of D_2 or 25-OH-D_2 by blood transport proteins, were found in the plasma of a number of chicks tested.

These findings suggest that resistance to the action of vitamin D_2 in the chick may be due, wholly or in part, to defective binding of D_2 and 25-OH-D_2 by the chick transport proteins resulting in lowered efficiency of the hepatic and/or renal hydroxylations of the vitamin and reduced delivery of the dihydroxy metabolites of vitamin D_2 to target tissues. Further investigation in other species known to be resistant to the action of vitamin D_2 will be important to establish whether similar correlations exist between biological activity and binding to the transport proteins. These results also suggest that selective measurement of vitamin D_3 and 25-OH-vitamin D_3 will be possible using the chick transport proteins, with little interference from D_2 or 25-OH-D_2. Simultaneous assays[9] using chick and rat plasma might then prove useful in distinguishing the relative concentrations of D_2 and 25-OH-D_2 (dietary sources) from D_3 and 25-OH-D_3 (sunlight exposure) in man and other species and, thereby, provide insight into the respective importance of environmental and dietary factors in supplying vitamin D requirements in man.

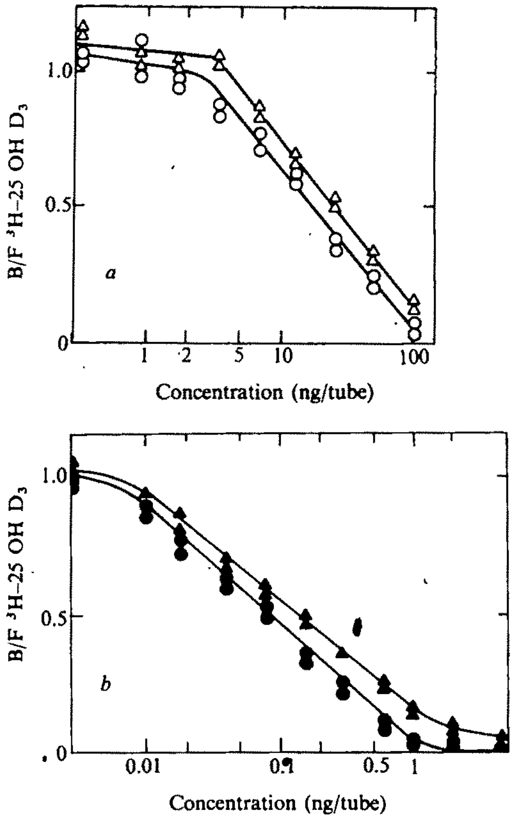

Fig. 2 Displacement of ^{3}H-25-OH-vitamin D_3 from D-deficient chick plasma with vitamin D analogues. The determination of B/F ratios for comparing binding of D analogues was accomplished with the procedure outlined in Fig. 1 except that chick plasma was used as a source of the specific D binding protein. Symbols as in Fig. 1.

These studies were supported by the John A. Hartford Foundation, the Kidney Foundation of Massachusetts, and the US Public Health Service. R. E. B. is a Medical Foundation Research Fellow.

An Inhibitor of Sterol Biosynthesis present in Cow's Milk

RECENT evidence indicates that sterol biosynthesis from acetate, but not from mevalonate, increases several-fold in the developing rat liver after weaning[1]. This increase parallels the postnatal rise in activity of liver 3-hydroxy-3-methylglutaryl-CoA reductase (HMG-CoA reductase), an enzyme which seems to catalyse the rate-limiting key reaction of hepatic sterologenesis both in the adult and in the developing rat[2,3]. Delayed weaning blocks the normal increase of HMG-CoA reductase which indicates that dietary factors are responsible for the observed changes, and rat milk was shown to contain an inhibitor of HMG-CoA reductase activity[2].

Here we present evidence that cow's milk, an important component of human diet, exhibits an inhibitory effect on rat liver sterologenesis both *in vitro* and *in vivo*. All experiments were performed on 5 to 6-week-old male Wistar rats. The animals were killed at the same time of day, between 1100 and 1200 h. Defatted cow's milk (fat content 2%, protein content 3.5%) was obtained from state controlled commercial sources, human milk directly from the patients of the Obstetric Clinic. A standard diet for laboratory animals, 'Bacutil'-Poland, called in the table 'solid food', was used, except where stated otherwise. As shown in Table 1, 10 μl cow's milk or 25 μl of human milk added to 2.6 ml of incubation mixture inhibited completely the incorporation of ^{14}C-acetate and ^{3}H-mevalonate into digitonin-precipitable sterols by liver preparations. The inhibitory activity of cow's or human milk resisted 10 min boiling and was found in the supernatant after protein had been precipitated from cow's milk with 5% lactic acid or 5% trichloroacetic acid (TCA). Overnight dialysis against Bucher medium[4] completely abolished the inhibitory effect of cow's milk. These facts suggest a low molecular weight and probably non-protein nature for the sterol synthesis inhibitor. It should be noted that, in contrast to our findings, the inhibitory activity of rat milk on HMG-CoA reductase was found to be non-dialysable.

Table 1 Effect of Milk on the Incorporation of ^{14}C-Acetate and ^{3}H-Mevalonate into Digitonin-precipitable Sterols by 600*g* Supernatant of Rat Liver

Additions (μl)		Specific radioactivity of sterols			
		^{3}H d.p.m. mg^{-1}	% of control	^{14}C d.p.m. mg^{-1}	% of control
None (control)		39,400	100	10,000	100
Cow's milk	10	780	2	—	0
Cow's milk boiled	10	800	2	—	0
Human milk	25	1,900	5	—	0
Human milk boiled	25	2,000	5	—	0
Cow's milk dialysed	25	38,800	100	9,800	100
Supernatant of cow's milk deproteinised with lactic acid, final conc. 5%	25	750	2	—	0

Neutralised lactic acid 5%	50	39,000	100	10,000	100
Neutralised trichloroacetic acid 5%	50	39,000	100	10,000	100

2.5 ml of 600*g* supernatant of 33% rat liver homogenate in 0.1 M potassium phosphate buffer, *p*H 7.4, 0.004 M $MgCl_2$, 0.001 M EDTA and 0.125 M sucrose 'Bucher medium'[4] was incubated at 37° C for 2 h with 1.0 μCi 1-^{14}C-acetate and 0.5 μCi 2-^{3}H-mevalonate in a total volume of 2.6 ml. Incubation was stopped by adding 15% KOH in methanol and the mixture was saponified at 65° C for 3 h with 4 mg of cholesterol added as carrier. The non-saponifiable lipids were extracted with hexane. The extracts were evaporated and digitonides were prepared according to Sperry and Webb[6]. The digitonides were dissolved in hot methanol and aliquots were taken for both radioactivity and sterol determinations. Sterols were assayed with the Liebermann-Burchardt colour reagent. The endogenous sterol content was 28 mg per 100 ml of supernatant fraction used. ^{3}H and ^{14}C radioactivity was analysed in a Nuclear Chicago Isocap 300 liquid scintillation counter using the scintillation fluid containing 100 mg POPOP and 4 g PPO per l toluene. The values represent the means of typical experiments run in triplicate.

Table 2. Effect of Dietary Cow's Milk on the Incorporation of ^{14}C-Acetate and ^{3}H-Mevalonate into Digitonin-precipitable Sterols by Rat Liver Slices

Group	Diet	Specific radioactivity of sterols	
		^{3}H d.p.m. mg^{-1}	^{14}C d.p.m. mg^{-1}
(1)	Solid food+drinking water (control)	4,470±580	15,400±1,270
(2)	Solid food+milk	4,600±420	7,300±1,290
(3)	Milk only	4,600±310	8,600±1,100

Each group consisted of three rats. The animals were kept for 3 d on the diet indicated. Daily intake of solid food in groups 1 and 2 was about 8.5 g per rat. Daily intake of milk was about 7 ml per rat in group 2 and 12 ml per rat in group 3. 0.5 g portions of liver slices obtained in duplicate from each animal were incubated at 37° for 2 h with 1.0 μCi 1-^{14}C-acetate and 0.3 μCi 2-^{3}H-mevalonate in 1.0 ml of Krebs-Ringer phosphate buffer, *p*H 7.4 (ref. 7). Incubation was carried out under continuous oxygen flow and was stopped by freezing. Tissue was separated from the medium and saponified at 65° C for 3 h in 5.0 ml of 15% KOH in methanol with 6.25 mg of cholesterol added as carrier. Further experimental details as in legend to Table 1. The endogenous sterol content was 2.2±0.2 mg per g of wet liver. The results of a typical experiment are presented. Values are the means from three animals±s.d.

To check whether cow's milk present in the diet could diminish the rate of hepatic sterologenesis, *in vivo* experiments were performed. As shown in Table 2, the incorporation of ^{14}C-acetate into sterols by liver slices obtained from rats fed milk diet for 3 d was about 50% lower than in the control. Sterol synthesis from ^{3}H-mevalonate, however, was not affected. It should be emphasised that cholesterol content in the standard diet was 0.36 mg g^{-1} and that defatted cow's milk used in our experiments contained about 8 mg of cholesterol per 100 ml. Since it is well established[5] that the feedback inhibition of hepatic cholesterogenesis by exogenous cholesterol requires at least 0.1% of cholesterol in the diet, it seems unlikely that the relatively small amount of cholesterol taken in with the milk would be the cause of the inhibitory effect observed in the rats of groups 2 and 3 (Table 2). Our conclusion is that a dialysable, TCA-soluble inhibitor of sterol synthesis exists in cow's milk. This inhibitor, although effective both *in vivo* and *in vitro*, affects sterol synthesis in a different way when added to the cell-free system than when fed to the intact animal. Whether the inhibitory effect on sterol biosynthesis from acetate and mevalonate is related to the same or different compounds present in milk remains to be solved. The properties and chemical nature of the milk inhibitor are under investigation.

DNA Breaks in Rifampin-treated *Salmonella typhimurium* LT2 after Exposure to Nutritionally Complex Media

We have reported the phenomenon of "minimal medium recovery" of heated *Salmonella typhimurium* LT2 (ref. 1) and how this phenomenon could be explained in terms of DNA damage caused by sequential exposure to heat and nutritionally complex medium[2]. We now show that treatment of *S. typhimurium* with rifampin also results in decreased viability on rich relative to minimal medium and that the DNA from these rifampin-treated bacteria exhibits breaks after exposure to a rich or complex medium.

When exponentially growing cultures of *S. typhimurium* in a glucose-mineral salts medium (M-9)[1] were exposed to 20 μg of rifampin per ml of medium for 15 min, the viable counts on M-9 agar plates remained constant while viable counts on trypticase soy agar, enriched with 0.5% yeast extract (TSY), showed a 99.0–99.9% reduction (Fig. 1). When the rifampin was removed, the TSY plate counts increased to the same level as before rifampin treatment within 2–3 h. The increase in TSY plate counts indicates repair of the damage produced by rifampin treatment. This observation is similar to the behaviour of heated *S. typhimurium*, although the mechanisms leading to TSY sensitivity may be different for both stresses (heat and rifampin treatments).

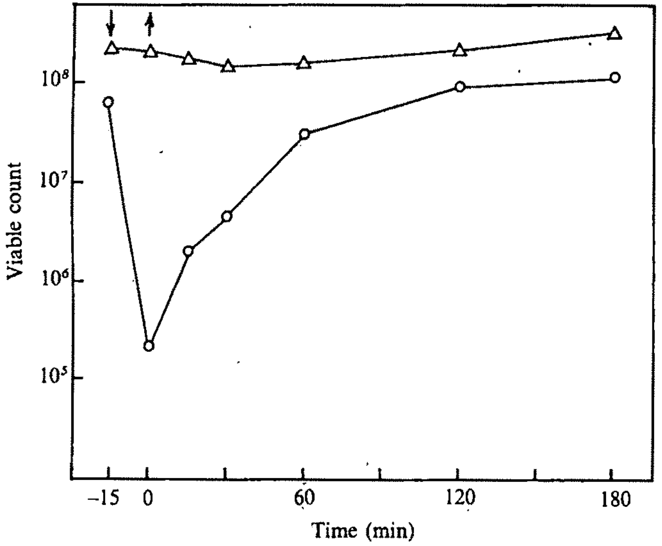

Fig. 1 Behaviour of *S. typhimurium* LT2 during and after incubation in M-9 with rifampin. An exponentially growing culture of *S. typhimurium* in M-9 broth was diluted (1 : 2) with M-9 broth containing 40 µg of rifampin per ml of broth. After 15 min of incubation at 37° C, 10 ml of broth was filtered on a Millipore membrane (HA 0.45 µm; 25 mm) and washed twice with 10 ml of M-9 medium prewarmed to 37° C. The filter was then resuspended in 10 ml of M-9 without rifampin and incubated at 37° C. Viability was assayed on M-9 (△) and TSY (○) plates. ↓, Addition of rifampin; ↑, removal of rifampin.

Since DNA from heated *S. typhimurium* exhibited breaks after exposure to TSY, we decided to repeat the same experiment with rifampin-treated bacteria. Radioactively labelled cells, grown in M-9 broth to the exponential phase, were treated with rifampin for 15 min and subsequently incubated in TSY for another 15 min. The cells were subjected to alkaline sedimentation analysis after rifampin and again after TSY incubation (Fig. 2*a*). The sedimentation patterns obtained show that rifampin treatment alone did not alter the weight-average molecular weight of DNA; but, when the rifampin-treated bacteria were exposed to TSY broth, the weight-average molecular weight was reduced ten-fold (Fig. 2*b* and Table 1). Control experiments demonstrated that exposure to TSY broth alone did not alter the sedimentation pattern of DNA. Likewise, as with heat, cells exposed to rifampin and then TSY lose viability when assayed on M-9 plates (Table 1) and also develop breaks in their DNA.

Table 1 Viability and DNA Weight-Average Molecular Weight of *S. typhimurium* LT2 after Incubation in M-9 with Rifampin followed by Incubation in TSY Broth

Treatment	Viable counts per ml M-9 plates	Viable counts per ml TSY plates	Weight-average molecular weight*
None	3.0×10^7	1.8×10^7	1.4×10^8
15 min in M-9+20 µg ml^{-1} RIF	4.0×10^7	4.8×10^5	1.4×10^8
15 min in M-9+20 µg ml^{-1} RIF followed by 15 min in TSY	2.0×10^6	2.0×10^5	1.2×10^7

RIF, rifampin.
* Computed from Fig. 2.

Figure 1 shows that rifampin-treated *S. typhimurium* recover their resistance to TSY if incubated in M-9 broth without rifampin. Table 2 shows that, in addition to the recovery of resistance to TSY broth, as assayed by viability on M-9 plates, DNA from rifampin-treated bacteria exhibited fewer breaks after incubation in TSY if they were previously incubated in M-9 broth. In other words, repair of rifampin-induced damage can be determined both by the ability of rifampin-treated bacteria to grow on TSY plates and by their resistance to TSY-induced DNA breakage.

Whether or not the reduced survival of rifampin-treated bacteria on TSY plates is a direct consequence of DNA breakage when these bacteria are exposed to TSY, it is interesting that rifampin-treated bacteria suffer DNA breakage when exposed to TSY. Bridges *et al.*[3,4], Woodcock and Grigg[5] and Sedgwick and Bridges[6] have proposed that DNA breaks after mild thermal treatments occur enzymatically; we concur. Along with Woodcock and Grigg[5], we propose that endonucleases recognise thermally denatured sections of the DNA molecule. Such enzymes have been generally reported to be present in *Escherichia coli* by Goldmark and Linn[7] and by Verly *et al.*[8]. In addition, we believe that these endonucleases are activated by TSY. It is then compelling to ask if and how rifampin renders the DNA molecule susceptible to nucleolytic activity.

We would like to advance the following model. It has been proposed[9] that transcription results in transient disruption of the DNA to DNA base pairing. Recently, it has also been shown[10] that *E. coli* RNA polymerase can bind to bacteriophage ϕX174 DNA replicative form and thus protect specific fragments from endonucleases. Since the addition of rifampin blocks initiation of transcription without affecting RNA chain elongation already in progress[11], it is possible that this situation could lead to transient regions of disrupted base pairing not protected by RNA polymerase. These regions would then be susceptible to endonucleases activated by TSY.

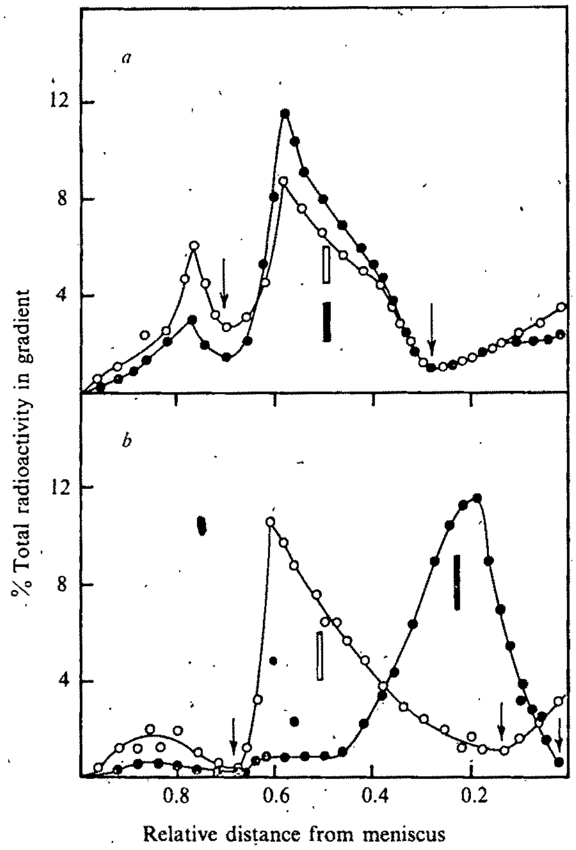

Fig. 2 Alkaline sedimentation of DNA from cells of *S. typhimurium* LT2 cultures incubated in M-9 with 20 µg rifampin per ml of broth at 37° C for 15 min followed by incubation in TSY for 15 min at 37° C. Cultures of *S. typhimurium* were grown to the exponential phase at 37° C in M-9 broth containing 250 µg of 2′-deoxyadenosine[13] and either 15 µCi of ^{3}H-thymidine-methyl (6.7 Ci mmol^{-1}, New England Nuclear Corp.) or 5 µCi ml^{-1} of ^{14}C-thymidine-methyl (51.5 mCi mmol^{-1}, New England Nuclear Corp.) of medium. ^{3}H-labelled cells were exposed to 20 µg of rifampin per ml of suspension for 15 min (*a*) and half of the cell suspension was then subjected to alkaline sedimentation analysis[2] along with half of the ^{14}C-labelled cells which were untreated and served as internal markers. The remaining half of the ^{3}H-labelled rifampin-treated cells were further incubated in TSY broth at 37° C for 15 min (*b*) and were then subjected to alkaline sedimentation analysis along with control ^{14}C-labelled cells. Centrifugation was done in a Spinco SW 50.1 rotor in a Beckman ultracentrifuge (L3–50) at 20° C for 40 min at 40,000 r.p.m. ○, ^{14}C-DNA; ●, ^{3}H-DNA. Arrows indicate limits within which DNA weight-average molecular weight was calculated[2]. Open and closed bars indicate position of DNA having the calculated weight-average molecular weight for ^{14}C and ^{3}H-labelled DNA respectively. Sedimentation is right to left. The fast sedimenting fractions in control and some of ^{3}H-labelled cultures are believed to be DNA-membrane complexes[14].

Rifampin inhibits RNA synthesis, not by blocking the initial binding of RNA polymerase to DNA[4,11], but more likely by inhibiting the transformation of the DNA•enzyme complex to an activated state, where enzyme and DNA change their conformation allowing the enzyme to bind to specific promoter sites on the DNA[12]. Then, if RNA polymerase protects DNA from TSY-activated nucleases, the protective form has to be the above mentioned activated RNA polymerase-DNA complex. Whether or not inhibition of RNA synthesis initiation with rifampin yields partially denatured DNA regions remains to be determined. It should also be mentioned that if rifampin intercalates between the bases of the DNA molecule, then this would also produce local denaturation. However, we do not know of any evidence that rifampin in fact intercalates between the DNA bases.

Table 2 Effect of Incubation of Rifampin-treated *S. typhimurium* LT2 in M-9 Broth Before Incubation in TSY Broth on Viability and DNA Weight-Average Molecular Weight*

Time in M-9 after rifampin treatment before TSY incubation (min)	Viability on M-9 after TSY incubation (cells ml^{-1})	Weight-average molecular weight after TSY incubation †
0	8.0×10^5	1.8×10^7
30	3.0×10^6	2.9×10^7
60	8.3×10^6	4.2×10^7
120	4.0×10^6	8.3×10^7
240	6.0×10^7	1.0×10^8
300	7.0×10^7	1.5×10^8

* Exponentially growing cells, as described in Fig. 2 legend, were exposed to 20 µg of rifampin per ml of M-9 broth for 15 min and were then washed free of rifampin and incubated in M-9 broth. At different times during M-9 incubation, portions of the cell suspension were exposed to TSY broth for 15 min at 37° C and were then subjected to alkaline sedimentation and viability analysis. Before rifampin treatment there were 6.8×10^7 viable cells per ml as assayed on M-9 plates.

† The DNA weight-average molecular weight before rifampin treatment was 1.5×10^8.

Indeed, although we have not shown that DNA breakage occurs through endonucleolytic attack, the alternative hypothesis of a physically-induced breakage is hard to visualise. It seems to us that both heat and rifampin cause a change in the cell such that, when exposed to nutritionally rich media, lethal DNA breaks ensue.

This investigation was supported by a grant from the US Food and Drug Administration, a US Public Health Service biomedical science support grant and a National Institutes of Health Toxicology Program grant.

Evidence for Individual Human Peripheral Blood Lymphocytes bearing both B and T Cell Markers

LYMPHOCYTES are composed of two main populations: thymus-derived (T) lymphocytes which are largely responsible for cell-mediated immunity, and bursal-equivalent or bone-marrow derived (B) lymphocytes which are primarily involved in humoral immunity. B cells can be identified by the presence of fluorescence-detectable surface immunoglobulin[1–3] and by their ability to bind antigen-antibody complexes or heat-aggregated immunoglobulin through the Fc portion of the immunoglobulin molecule[4–7]. Human T cells can be identified by their ability to form non-immune rosettes (E rosettes) with sheep red blood cells (SRBC)[8–12]. We report here that when these B and T cell markers were evaluated simultaneously on individual cells, a small subpopulation reproducibly bore both markers. Further experiments seemed to rule out artefact as an explanation.

Lymphocyte separation and fluorescent detection of surface Ig and aggregated immunoglobulin-binding were performed as before[5,6]. Briefly, peripheral blood lymphocytes (PBL) were isolated from venous blood by Ficoll-Hypaque density flotation followed by passage over nylon fibre columns. The purified PBL were incubated with polystyrene beads and cells adhering to or phagocytosing the beads were discounted. After thorough washing, PBL were incubated with either rhodamine-conjugated anti-human Ig (specific for γ, μ, α, κ, λ) or fluorescein-conjugated heat-aggregated human immunoglobulin, washed again thoroughly, and evaluated by alternate phase contrast and fluorescent microscopy for the percentage of positive cells.

E rosettes were prepared as described before[12], with minor modifications. Purified PBL and neuraminidase-treated SRBC were incubated together at 37° C, pelleted at 200*g*, and incubated at 4° C for a minimum of 30 min. The pellet was resuspended gently and counted by phase contrast microscopy. Lymphocytes were considered E-rosette-positive if SRBC were adherent. Approximately 90% of E rosettes involved three or more SRBC.

B and T cell markers were evaluated simultaneously on individual cells by first staining the PBL with the appropriate fluorescent reagent, washing thoroughly and then applying the rosetting technique. Individual cells were then viewed alternately under phase contrast and fluorescent illumination and scored for the presence of one, both or neither marker.

Peripheral blood lymphocytes from nine normal donors (two of the nine subjects were studied twice) were evaluated for percentages of B (surface Ig-bearing, aggregated Ig-binding) and T (E-rosette-forming) cells. Tests for the three markers were performed both separately and simultaneously (surface Ig+E rosettes and aggregated Ig-binding+E rosettes) for each patient on the same day using the same reagents (Table 1). Using the markers separately there was good agreement between markers both for individual donors and the group as a whole. Addition of the percentages for E rosettes and either of the B cell markers accounted for nearly all the lymphocytes (96.7 to 97.7%, range 89.0 to 102.5%). The data agree well with others[8,13]. Individual donors ranged widely in their populations of B and T cells and the same donor occasionally varied from day to day.

When these B and T cell markers were evaluated simultaneously on individual cells, a small subpopulation (mean 3.6%, range 1.0 to 6.0%) of lymphocytes bearing both markers was observed (Fig. 1). Several observations suggested that the detection of both markers on the same cell was not an artefact. (1) Each individual marker gave equivalent results whether evaluated separately or by the simultaneous technique (that is percentage surface Ig-bearing cells (separate) ≃ percentage surface Ig-bearing cells plus double marker cells (simultaneous)). Thus the markers seemed not to interfere with each other, and this suggested that use of the simultaneous technique was valid. (2) Almost all (>95%) double marker cells were heavily rosetted and therefore apparently had at least as high an affinity for SRBC as the usual T cell. (3) It seemed unlikely that the double marker cells were monocytes since they did not adhere to nylon, did not phagocytose and met the morphological criteria of small lymphocytes. Furthermore, monocytes apparently do not bind SRBC under the conditions of the E rosette test[8,11,12]. (4) An equivalent number of cells bearing both B and T cell markers was observed whether the B cell marker was surface-Ig-bearing or aggregated Ig-binding. These two markers have been shown to be independent[5–7]. (5) The simultaneous technique using E rosettes formed with non-neuraminidase-treated SRBC (such rosettes

‡ PHA concentration, culture conditions and length of culture were optimised to achieve maximal blastogenic response for the donor.

were more fragile and required longer contact at 4° C between PBL and SRBC) showed the same number of double marker cells. Thus, neuraminidase treatment of SRBC was not responsible for the double marker cells. (6) Double marker cells were not due to anti-SRBC antibodies. Several of the normal subjects (He, Co, Bu) were tested and had no such antibodies by haemagglutination. Furthermore, one patient with infectious mononucleosis and high titre anti-SRBC antibodies showed a percentage of double-marker cells (1.5%) comparable with normal donors. Also, the anti-Ig used in the simultaneous technique would be expected to inhibit SRBC binding by such antibodies. (7) It seemed unlikely that the double marker lymphocytes represented spontaneous antigen binding cells since the latter represent 0.14% or less of the nucleated cells in normal mouse blood[14]. (8) The simultaneous technique applied to lymphocytes which had not been passed over nylon fibre showed the same number of double marker cells. Thus lymphocyte contact with nylon was not responsible for the double marker cells.

It was reasoned that if double marker cells were produced by technical factors, then any lymphocyte population studied by the simultaneous technique would show such cells. Conversely, if cells bearing both B and T cell markers were a real subpopulation of PBL, then "clonal" lymphocyte populations should show few or no such double marker cells. One lymphoblastoid cell line and three patients with chronic lymphocytic leukaemia (CLL) were evaluated. The three CLL patients had white blood cell counts >50,000^{-3}, and in two cases the cells were of B cell origin and in one case apparently of T cell origin (Table 2). Double marker cells were virtually absent in these populations, thus supporting the view that cells bearing both B and T cell markers are a real subpopulation of PBL.

A markedly increased number of double marker cells (20.0% of PBL) has been encountered in a patient with hypogammaglobulinaemia (manuscript submitted). The meaning of this observation remains to be elucidated.

Attempts to remove (by trypsin digestion) and then regenerate surface Ig in normal PBL were unsuccessful and, therefore, direct evaluation of whether the double marker population represents T cells with the ability to adsorb Ig was not possible. As an alternative approach, normal PBL were evaluated for cells bearing both B and T cell markers both before and after stimulation by phytohaemagglutinin (PHA) in the presence of autologous serum (Table 3). PHA-stimulated PBL gave results equivalent to the controls, that is no increase in double marker cells was noted. Thus, PHA-

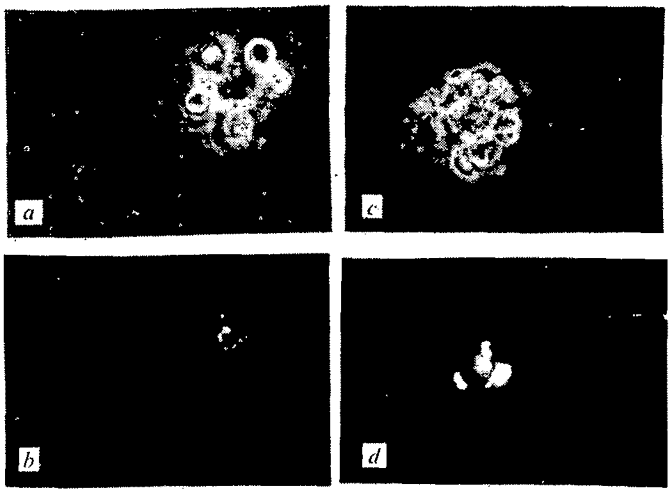

Fig. 1 Demonstration of normal human peripheral blood lymphocytes bearing both B and T cell markers. *a*, Phase contrast illumination of E-rosetted lymphocyte which under fluorescent illumination; *b*, reveals staining with rhodamine-conjugated anti-human Ig. Ig staining is clumpy because of incubation at 37° C during the E-rosette technique. *c*, Phase contrast illumination of E-rosetted lymphocyte which under fluorescent illumination; *d*, reveals binding of fluorescein-conjugated aggregated Ig. (×900.)

stimulated human PBL did not seem to adsorb Ig. Nevertheless, this does not rule out the possibility that *in vivo* stimulated or antigen-stimulated T cells possess this property.

Lymphocytes bearing neither B nor T cell markers ('null') were also found by the simultaneous technique (mean 5.0%, range 2.0 to 13.0%). This observation must be interpreted cautiously because of the fragility of E rosettes; however, 'null' cells may also represent a real subpopulation, as suggested by studies with the mouse[15].

Other investigators failed to detect lymphocytes bearing both B and T cell markers[8,9,13], but our study differed in several respects (methods of lymphocyte purification, specificity of antisera, intensity of fluorescent illumination, methods of preparation of E rosettes) which may account for this discrepancy. On the other hand, Bentwich *et al.*[11] reported double marker cells among the PBL of normal donors.

Some murine lymphoma lines have been reported which bear theta antigen, surface Ig and a receptor for Ig[16,17]. Such tumours could represent neoplastic transformation of a lymphocyte type normally present, and thus provide indirect evidence for the existence of a population bearing both B and T cell markers.

The nature of cells bearing both B and T cell markers remains unclear. Recent reports have presented evidence that some T lymphocytes can adsorb cytophilic antibody[18], and that antigen-activated T cells can bind antigen-antibody complexes[19] and bear easily detectable surface Ig[20]. If double marker cells prove to be activated T cells, the simultaneous technique should provide a method for identifying and isolating such cells. Alternatively, double marker cells may represent a subpopulation of B lymphocytes which can form E rosettes. Bentwich *et al.* reported that after neuraminidase treatment of PBL, a subpopulation of lymphocytes bearing surface Ig and the Fc receptor will form E rosettes[21]. However, electron microscopy has shown that such binding is different from the binding of SRBC to untreated PBL[11,21]. Thus, this observation may not be relevant to the data reported here. The third and most interesting possibility is that double marker cells may be able to function as B and (or) T lymphocytes, either as multipotential effector cells, or by further differentiation.

The study reported here provides evidence for the existence of a real subpopulation of lymphocytes bearing both B and T cell markers. Such evidence makes it necessary to reconsider the concept that all lymphocytes belong to one or the other of two distinct classes.

Autoradiographic Visualisation of Paternal Chromosomes in Mouse Eggs

THE paternal component of the genome has been localised in the nuclear chromatin of early cleaving mouse eggs[1] by autoradiography following the mating of normal females with males in which the spermatogonial cell line was labelled *in vivo* with tritiated thymidine (^{3}H-TdR). The results indicated that in at least the earliest developmental stages of the mouse zygote there is a separation of maternal and paternal chromatin. This extends to mammals the concept of gonomery well known in lower animals[2]. The interpretation of these findings, as well as further exploitation of this experimental system, relies on the distribution of paternal labelled chromosomes at metaphase in early cleavage. An expected separation into twenty labelled and twenty unlabelled chromosomes is most unlikely to occur by chance. Here we present an analysis of the distribution pattern of the labelling in chromosomes.

Mice of the inbred CBA/H-T6/T6 strain were used. Intratesticular injections of ^{3}H-TdR in males, mating with superovulated females, checking of the days of peak production of labelled sperm, collection of zygotes in the oviducts, spreading by air-drying[3], preparation and staining of autoradiographs, were performed as described previously[1]. The time of collection of the zygotes, calculated from the time of the appearance of the vaginal plug, however, was selected for obtaining eggs close to or at the four cell stage (60 h post-mating). In addition, well-spread metaphases of cleaving eggs were obtained by injecting colchicine directly into the uterine lumen 2 to 4 h before killing the pregnant mice. It must also be pointed out that the intratesticular injection of ^{3}H-TdR results in continuous availability of the tracer for at least 2 d (ref. 4).

Out of 428 well-fixed eggs from 264 females examined, 129 were in metaphase. Of these, forty-one contained twenty labelled chromosomes and eighty-eight had grains in less than twenty chromosomes. Particularly well-spread metaphases allowed arrangement into karyotypes (Fig. 1) in which the paired assortment of homologous chromosomes was established, including the sexual pair and the small translocated T6 marker. The number of labelled chromosomes never exceeded twenty in any metaphases observed, thus giving an autoradiographic visualisation of the classical laws of Van Beneden and Boveri[2], namely that the number of chromosomes contributed by each parental pronucleus to the diploid zygote is haploid. Labelling of only part of the presumed paternal component, which varied from one to nineteen labelled chromosomes, is probably due to fertilisation by sperm derived from spermatogonia which were exposed to ^{3}H-TdR only during the late part of DNA synthesis. In fact, approximately one-half of the partially labelled metaphases had a labelled chromosome morphologically identifiable as a late-

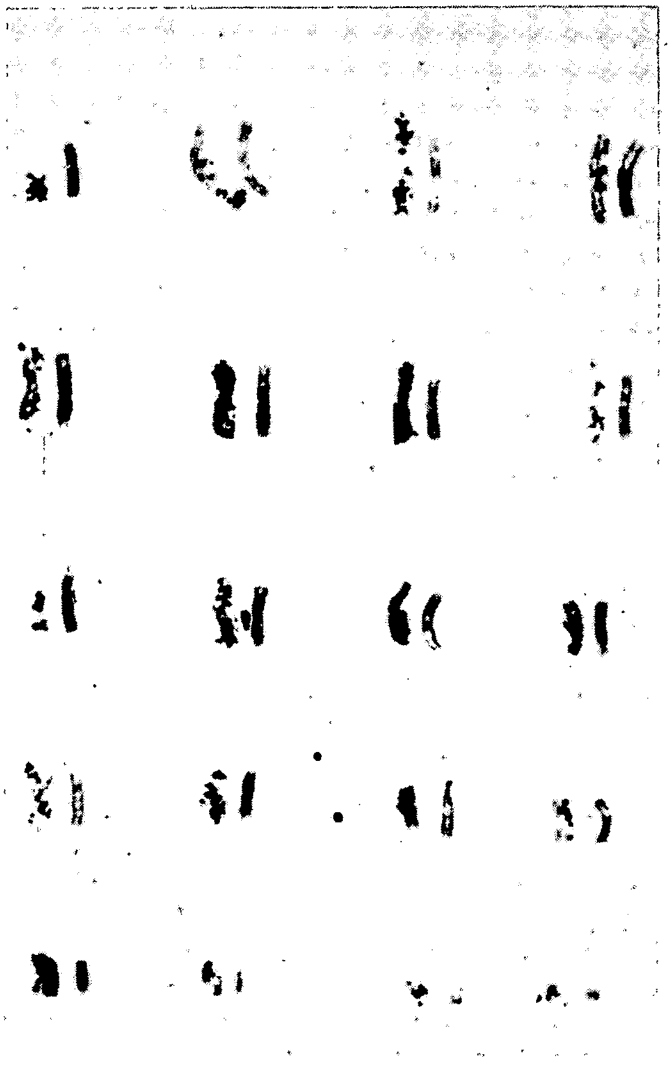

Fig. 1 Karyotype of a metaphase in a mouse egg at the second division of cleavage. The paternal chromosome in each homologous pair is labelled, the maternal is not, including the XY sexual pair (top left) and the T6 marker (bottom right).

labelling Y chromosome. Moreover, only the Y was labelled in all male metaphases in which only one chromosome contained grains. This is consistent with the late replication of DNA by the Y chromosome before meiosis in male mice[4]. Labelling of autosomes in the partly labelled metaphases varied markedly both in the localisation of grains over different parts of the chromosomes and in the number of labelled chromosomes. The labelling pattern generally corresponded to morphological distinctions previously made on meiotic autosomal bivalents[4], based on the observation that the late replicating parts of the genome are heterochromatic.

It cannot be excluded that tritium-induced lesions cause morphological anomalies. Even if these may have been missed because of the previous selection of morphologically well-preserved eggs in which extensive exchanges between homologous chromosome pairs had not occurred, the observed labelling pattern cannot have been generated by radiobiological effects.

It must also be emphasised that the relative proximity of labelled or unlabelled chromosomes on spread metaphase preparations does not necessarily reflect their relative position in the living unfixed egg. Indeed, phase contrast microscopic examination of the eggs during the fixation and spreading revealed distortion of the original interchromosomal arrangement.

These results indicate that an expected distribution of labelled chromosomes on metaphase plates at subsequent mitoses can be observed in eggs fertilised by ^{3}H-TdR-labelled sperm.

Allelic Contracomplementation Possible Mechanism for Initiating Sympatric Speciation

IN *Drosophila melanogaster*, certain heterozygous combinations of viable alleles of the sex-linked Abruptex locus are lethal. This new type of allelic interaction has been called contracomplementation[1]. The phenomenon is equivalent or related to negative complementation, but the term contracomplementation is more descriptive in this specific case. The following heterozygous combinations of viable Abruptex alleles are found to be lethal: Ax^{9B2}/Ax^{E2}, Ax^{9B2}/Ax^{16172} (ref. 2), Ax^{28}/Ax^{71d} (ref. 1), Ax^{71d}/Ax^{9B2}, and Ax^{28}/Ax^{16172}. Interallelic complementation has been supposed to have certain evolutionary significance; it is an intermediate stage in the evolution of heteromultimeric proteins, such as human haemoglobin, from homomultimeric proteins[3]. Thus, interallelic complementation may be a stage in the progressive evolution of a population. Contracomplementation as an opposite of complementation should accordingly have an 'opposite' evolutionary significance, being an initiation mechanism in splitting one population into two parts, that is an initiation mechanism of sympatric speciation.

Sex-linked genes of different laboratory stocks of *D. melanogaster* which carry contracomplementing alleles of the *Ax*-locus never recombine (except by laboratory manipulations). Supposing that contracomplementing alleles are in the autosomes, stocks carrying such alleles are conceptually different species because they are reproductively isolated from each other. If we presume that a uniform natural population consists of a^+/a^+ individuals and two contracomplementing mutations, a^x and a^y, occur with a certain rate in this population, the frequency of the mutant allelles will increase if both mutations are favoured by selection (a^x/a^x, a^x/a^+, a^y/a^y, and a^y/a^+ individuals have greater fitness than a^+/a^+ individuals). If, because of contracomplementation, a^x/a^y individuals are lethal or otherwise less fit than other genotypes, the population will virtually split into parts, one containing a^x alleles and the other a^y alleles because genes prohibiting mating between individuals carrying a^x and a^y alleles become beneficial. It is thus suggested that contracomplementation is a possible initiation mechanism of sympatric speciation but the allelic interaction process itself should be studied more profoundly.

No Mouse PMN Leukocyte Depression after Inoculation with Brain Tissue from Multiple Sclerosis or Spongiform Encephalopathies

RECENT experiments by Carp *et al.*[1,2] and Licursi *et al.*[3] have excited hopes among investigators of multiple sclerosis (MS) and slow virus infections of the central nervous system that an experimental marker for these diseases has finally been found. Tissues from humans with MS or from scrapie mice were inoculated into normal mice, which showed a polymorphonuclear leukocyte (PMN) depression beginning within 1 to 3 d of the inoculation and persisting many months thereafter.

We report here our failure to confirm these results for MS and scrapie or to obtain a PMN depression with the human subacute spongiform virus encephalopathies, kuru and Creutzfeldt–Jakob (C–J) disease.

C57Bl/6J mice were obtained from the Jackson Laboratories, Bar Harbor, Maine. They were distributed into test groups of not more than six mice per cage and held for 2 weeks before experiments were begun. No fighting was observed. No antibiotics were added to their diet of water and mouse chow.

Scrapie mouse brain was used from tenth mouse brain passage of the Compton strain, originally isolated from sheep and previously passaged nine times in goats. Normal mouse brain was prepared from healthy adult NIH Swiss–Webster mice. Kuru chimpanzee brain was obtained from chimpanzee A191, inoculated with fourth passage chimpanzee brain material from the Eiru strain. This animal showed the typical clinical and pathological features of kuru, and the inoculum used in the present experiment has transmitted kuru in subsequent chimpanzee passage. C–J chimpanzee brain was obtained from chimpanzee A122, inoculated with first passage chimpanzee brain material from the Woolfe strain. This animal showed the typical clinical and pathological features of C–J disease, but its tissues have not been re-inoculated into primates. Normal chimpanzee brain was obtained from an uninoculated healthy young adult animal. Each of the above brain tissues was ground in a mortar and pestle using sterile sand, diluted to a 10% (w/v) suspension in phosphate-buffered saline, *p*H 7.4, centrifuged for 20 min at 2,000 r.p.m., and the supernatant fluid stored at −70° C until use. Human MS brain was prepared from autopsy material obtained from patient L. K. who had had a characteristic relapsing illness for 5 yr and had multifocal plaques throughout the white matter of the brain. A coronal section was dissected into grey and white matter, the tissues separately homogenised in an ice-cooled Sorvall blender for a total of 1 min, diluted to a 10% (w/v) suspension in Eagle's Basal Medium, and after centrifugation for 20 min at 2,000 r.p.m. the supernatant fluid was stored at −70° C until use. In addition, Dr Richard Carp provided coded aliquots of a pooled suspension of 10% (w/v) normal human brain and MS human brain. Details of their preparation are described elsewhere[1].

All inoculated mice received 0.03 ml volumes of the dilutions intracerebrally. For leukocyte measurements, blood was drawn into capillary pipettes from which a drop was released for the immediate preparation of slides. 20 μl of the remaining blood was quickly mixed with 10 ml of Isoton in plastic cuvettes to which 3 drops of Zap-Isoton was added, and the white blood cell (WBC) counts measured in a Model B Coulter Counter. The Wright's stained slides were coded and a 200 cell differential count was performed to obtain the percentage of PMN cells. The code was broken only at the end of each experiment.

Results of the PMN counts in each of three experiments are shown in Table 1.

In experiment one, groups of ten mice were inoculated with each tissue homogenate, and each inoculum group was separately caged. Individual mice in each cage were identified by an ear snip pattern. Mice were bled retro-orbitally without anaesthesia, and each mouse was bled before inoculation and weekly thereafter for 4 weeks.

Instead of a depression there was an elevation of the PMN count in all groups, and the differences between groups were not significant. If only those counts lower than 20% are analysed, the total number of post-inoculation determinations is reduced from 200 to 129, and the average PMN counts to between 12 and 15%—again with no significant differences between the groups. WBC counts were also elevated from pre-inoculation averages between 6,500 and 9,000 cells mm^{-3} to levels from 10,000 to 13,500, with a tendency for entire cages of mice to show comparable elevations in any given week. The mice inoculated with normal mouse brain and those inoculated with scrapie mouse brain were held several more months. All scrapie mice died between 5 and 7 months following inoculation. All normal mice remained well.

Table 1 Percentage of PMN in C57Bl/6J Mouse Blood Before and After Intracerebral Inoculation of Brain Tissue Extracts

Inoculation group	0	Weeks after inoculation 1	2	3	4	Post-inoculation average
Experiment 1						
Normal mouse	12	15	12	24	24	19
Scrapie mouse	9	15	17	17	19	17
Normal chimp	8	16	13	21	14	16
Kuru chimp	9	15	14	16	17	16
C-J chimp	10	26	22	19	24	23
Experiment 2						
Uninoculated	10	16	13	11	11	13
MS (white)	10	11	15	—	15	13
MS (grey)	10	11	14	12*	13†	13
MS pool	10	13	8*	13†	12	11
Normal pool	10	12	16	12*	14	13
Experiment 3						
Uninoculated	14	13	8	9	9	10
Scrapie mouse	14	12	—	13	9	11
MS pool	14	13	11	10	8	10
Normal pool	14	16	8	8	10‡	10

All percentages are based on 200 cell differential counts of Wright's stained blood smears. There are ten mice per experimental point in experiment 1, four mice per point in experiment 2 and five mice per point in experiment 3.

* 3 mice in group.
† 2 mice in group.
‡ 4 mice in group.

In experiment two, sixteen cages containing six mice per cage were handled as follows. One mouse from each cage was bled for control counts on the day of inoculation. The remaining five mice were identified by an ear snip pattern, one was inoculated with each of the four tissue homogenates and the fifth mouse left uninoculated. Four cages of mice were bled and then discarded each week for 4 weeks (each mouse was thus bled only once) giving four mice per experimental point. Mice were bled retro-orbitally without anaesthesia.

From a pre-inoculation average PMN count of 10%, slight average elevations occurred which were not significantly different one from another. The single exception was a depression during the second week in the group of mice inoculated with the pooled human MS brain. This depression was no longer evident in the following 2 weeks, and the combined 4 week values were not significantly different between groups. WBC counts remained in the 5,000 to 10,000 range throughout the experiment.

In experiment three, sixteen cages containing six mice per cage were handled as in experiment two, except that, following the control bleeding, all mice in each of four cages were inoculated with a given tissue homogenate, and four cages of mice were left uninoculated. Each week for 4 weeks one cage of five mice having received one of the homogenates and one cage of uninoculated mice were bled and discarded. Mice were anaesthetised with ether for 30 s and bled from the exposed axillary vessels.

From a pre-inoculation average of 14%, the PMN counts tended to fall slightly, but in no case was the depression significantly different between the inoculated and uninoculated groups of mice. (One cage of scrapie-inoculated mice had PMN counts between 30 and 75% 2 weeks after inoculation and are omitted from the table.) The combined 4 week values were virtually identical, and not significantly lower than the pre-inoculation average. WBC counts remained in the 4,000 to 9,000 range throughout the experiment.

WBC and PMN counts from the first experiment suggested that a leukocyte stimulus was operating in all groups of mice irrespective of the inoculum given. Cage infections appeared the most likely cause, but sporadic eye infections, anxiety of the unanaesthetised mice, and repeated bleedings of the same mice may also have contributed to the results. Whatever the stimulus, it was uninfluenced by inoculation of scrapie, kuru, or C–J disease-infected brain compared with normal brain. This was equally true when instead of all the data, 'high' PMN counts ($\geq 20\%$) were excluded from analysis. Thus it could be said that if a PMN depressing factor was in fact produced by the infected brain homogenates, it was totally overcome by exogenous leukocyte stimulation.

In the second experiment, by using each mouse only once, randomising the mice within cages, and including uninoculated controls, we were able to avoid the leukocyte stimulus seen in the first experiment. We also included inocula given by Dr R. I. Carp from MS and normal brain tissue that had produced in his laboratory definite PMN depression (MS) and no PMN depression (normal). We found no effect from either these or our own inocula.

A final experiment was then done in which mice were anaesthetised and bled from the axillary vessels, duplicating the technique used by Carp. We also used new aliquots from his MS and normal brain pools. The scrapie material used, as also in our first experiment, was that which we had originally given to Carp for his experiments[2,3]. Once again, we were unable to distinguish between any of the inoculated groups and the uninoculated group, although there was an overall trend to slightly lowered PMN counts during the 4 week period of study.

We must thus conclude that in spite of efforts to duplicate exactly the protocol of the Staten Island group, using the same strain of mice purchased from the same source, some of the same inocula, and the same methods (including the bleeding technique), we cannot confirm that either scrapie or MS brain tissue inoculated into mice depresses the PMN count, nor have we seen any effect in mice inoculated with brain from kuru or C–J disease.

We thank Dr C. J. Gibbs, jun., for supplying the specimens of chimpanzee brain tissue, and Dr R. I. Carp, who supplied the coded aliquots of MS pool and normal pool inocula. We also thank Mr Timothy Slater, Miss Elizabeth Adler and Miss Nancy Henly for technical assistance.

Sensitivity of Human Foetal Intestine to Interferon

ACUTE infectious non-bacterial gastroenteritis is a common disease in which recovery usually occurs within 24–48 h of the onset of diarrhoea and vomiting[1,2]. This short duration suggests that a mechanism of rapid onset, such as interferon, may play a significant role in recovery. The role of interferon in recovery from acute enteric viral infections of man is, however, unknown. Indeed, little is known about the ability of the human intestine to either produce or respond to interferon. We have therefore investigated the role of interferon in viral infections of the human gut. We found that human foetal intestine is quite responsive to the antiviral properties of exogenous interferon, and when so treated exhibits a marked inhibition of the replication of an enteric virus, echovirus type 11.

Previous studies of interferon in intestinal secretions have yielded little information because of the rapid proteolytic enzymatic inactivation of interferon, in spite of the addition of trypsin inhibitors[3]. We have also found that interferon is inactivated completely when added to human duodenal secretions at a final concentration of 500 U ml^{-1}, even when the secretions first have soybean trypsin inhibitor type II-S added at a concentration of 0.67% or foetal calf serum at a concentration of 16%.

A new technique for maintaining fragments of human foetal small intestine in organ culture for up to 3 weeks[4] presents a unique opportunity to study the role of interferon in human intestine, free from proteolytic enzymes. Unlike monolayer cell cultures, organ cultures maintain the *in vivo* anatomic relationships as well as certain physiological functions of the intestine[4]. Human foetal intestinal organ cultures were prepared and maintained as previously described[4]. Human interferon was prepared in human leukocytes stimulated by ultraviolet irradiated Sendai virus, using the method of Cantell[5], and was provided by Drs S. Baron and C. Buckler.

Figure 1 summarises the procedure and results of an experiment in which organ cultures were pretreated for 18 h with exogeneous human interferon and then challenged with echovirus 11. In the absence of interferon, echovirus 11 replicated to titres comparable with those reported in intestinal organ cultures[6]. By contrast, cultures pretreated for 18 h with 5 U ml^{-1} (reference units, see below) or more of interferon failed to support virus replication. Interferon pretreatment with less than 5 U ml^{-1} permitted virus growth. It is impossible at present to study in this way the replication of aetiological agents of acute infectious non-bacterial gastroenteritis, such as the Norwalk agent[2], because there is no assay system available except human infectivity[2].

Having demonstrated the sensitivity of human foetal intestinal organ cultures to interferon, we attempted to determine whether these cultures could be stimulated to synthesise interferon. Several potential inducing agents were used, including polyriboinosinic polyribocytidylic acid[7] (poly(I)·poly(C), Microbiological Associates, Bethesda, Maryland), echovirus type 11, and the Norwalk agent from a filtrate known to be infectious for man. Several other techniques which augment interferon production were also used; these included interferon priming[8], diethylaminoethyl (DEAE) dextran[9,10] (Pharmacia), and treatment after induction with cycloheximide[11,12] (Sigma). Table 1 summarises

Table 1 Attempts to Stimulate Interferon Production by Human Foetal Intestinal Organ Cultures

Experiment	Priming with human interferon 10 U ml^{-1}		Inducing agent*			Post-induction augmentation	Interferon assay
	5 h incubation at 36° C	18 h incubation at 36° C	Poly (I) · poly (C) 50 μg ml^{-1} + DEAE-dextran 100 μg ml^{-1} for 90 min	Echovirus 11, 1,000 TCID$_{50}$	Norwalk agent 0.3 ml of 1 : 10 dilution	Cycloheximide 10 μg ml^{-1} for 3 h	Media/explants
1	−	−	+	−	−	−	Negative/negative
2	+ †	−	+	−	−	−	Negative/not done
3	−	+	+	−	−	−	Negative/negative
4	−	+	+	−	−	+	Negative/negative
5	−	−	+	−	−	+	Negative/negative
6	−	−	−	+ ‡	−	−	Negative/negative
7	+	−	−	+	−	−	Negative/negative
8	−	−	−	−	+	−	Negative/negative
9	+	−	−	−	+	−	Negative/negative

For priming, interferon was added in 1.25 ml of media to cultures, incubated as indicated, and cultures were then washed three times with fresh media and exposed to inducing agent.

For poly(I)·poly(C) and DEAE-dextran induction, poly(I)·poly(C) of a lot known to induce interferon in human leukocytes and DEAE-dextran were added in 1.25 ml of media to cultures as indicated. Plates were then washed three times, renewed with media, incubated at 36° C for 20 h, and fluids were then collected, as were explants, and frozen at −80° C until assayed for interferon. In experiments 4 and 5, cultures were incubated as indicated with cycloheximide, after removal of poly(I)·poly(C)-dextran, then washed three times, renewed with media, incubated for 20 h, and fluids and explants were then collected.

For virus inoculation, echovirus 11 or Norwalk agent (8FIIa filtrate) was added in 1.5 ml of media to cultures as indicated. Plates were then incubated at 36° C for 20 h, and fluids were collected, as were explants, and frozen at −80° C. Explants from duplicate plates were freeze-thawed three times in 1.5 ml media, and homogenised in a glass tissue homogeniser. Clarified fluid collections and tissue homogenates were ultraviolet-irradiated for 8 min at 2.5 inches from an Atlantic germicidal 282L-20 ultraviolet light bulb, an intensity shown to inactivate completely the infectivity of 10^6 TCID$_{50}$ of echovirus 11.

Interferon assay was performed on undiluted and 1 : 5 diluted media and explant homogenate collections, using the VSV cytopathogenicity inhibition assay in human foreskin fibroblast cells.

* Induction was also attempted using 100, 50, 10 and 1 μg ml^{-1} of poly(I)·poly(C) alone for 1 and 18 h.

† This experiment was also performed using 100 U ml^{-1} of interferon.

‡ This experiment was also performed using 10^6 TCID$_{50}$ echovirus 11.

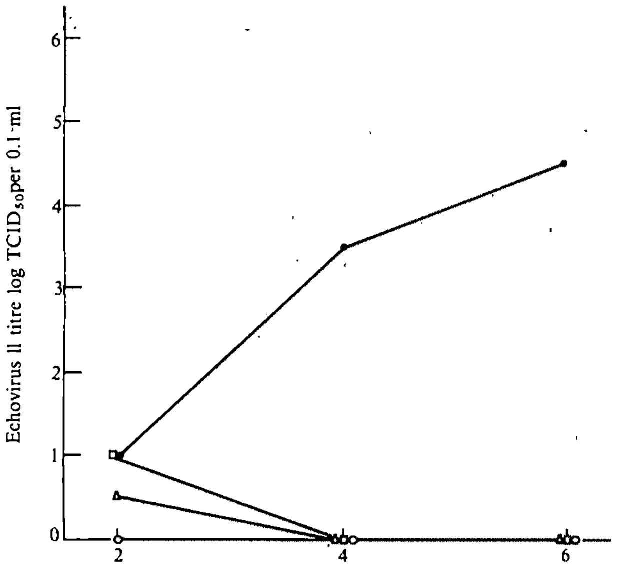

Fig. 1 Effect of exogenous human interferon on echovirus type 11 replication in human foetal small intestinal organ cultures. Organ cultures were prepared from foetal intestine 12–18 weeks old, and maintained for 5 d at 36° C, with the media changed every other day before the start of experiment. Cultures were pretreated with the indicated doses of human interferon in 1.25 ml media for 18 h and then washed three times with fresh media. Echovirus 11, 100 TCID$_{50}$, was then inoculated per culture dish for 4 h at 36° C; cultures were then washed three times with fresh media, renewed with appropriate interferon-containing media, and incubated. Fluids were collected and cultures refed with appropriate interferon-containing media on days 2, 4, and 6 after virus inoculation. All experiments were run on duplicate plates with pooling of collected fluids. Assays for echovirus in collected fluids were performed in WI-38 cells. ●, Control; ○, 20 U ml^{-1} interferon; □, 10 U ml^{-1} interferon; △, 5 U ml^{-1} interferon.

the procedure and results. In no case could we demonstrate interferon synthesis by human foetal intestinal organ cultures using the VSV cytopathogenicity inhibition assay[13]. These results were obtained in assays in which known positive control preparations of 5 U ml^{-1} of human leukocyte interferon could be detected. The standard reference human interferon 6,787 titres 100 U ml^{-1} by this method and the standard reference human interferon 6,919 titres 5,000 U ml^{-1} by this method.

Our demonstration of the sensitivity of human foetal intestine to exogenous interferon was made possible by a newly developed intestinal organ culture technique. This technique has obviated in part the experimental difficulties in studying the role of interferon in the gastrointestinal tract posed by proteolytic enzymes in intestinal secretions. Indeed, because of the rapid inactivation of interferon in intestinal secretions, it is doubtful whether intraluminal interferon plays any role in the recovery from viral infections of the gastrointestinal tract. Rather, it is possible that interferon may spread cell-to-cell within the intestinal mucosa, as has been suggested in other tissues[14].

The inability to demonstrate synthesis of interferon by human foetal intestinal organ cultures does not necessarily imply that adult intestine *in vivo* cannot produce interferon. On the other hand, it may be that while the intestine is sensitive to the effects of interferon, cells normally present in adult intestine are unable to produce interferon. In this regard, we have recently demonstrated that one of the most significant pathological features during acute illness with the Norwalk agent of non-bacterial gastroenteritis is a marked round cell infiltration in the lamina propria of the proximal small intestine[15]. It is known that lymphocytes possess the ability to synthesise interferon[16,17]. Conceivably, the round cell infiltrate induced by the Norwalk agent could synthesise local interferon, which in turn could protect the intestine from further viral replication and account for the rapid recovery usually seen in acute infectious non-bacterial gastroenteritis.

This work was supported by a contract with the US Army Medical Research and Development Command. We thank Dr R. Rafajko of North American Biologicals, Inc., Rockville, for assistance with interferon assays, and Dr M. Oxman of Children's Hospital Medical Center, Boston, for helpful advice.

Hydroxyapatite formed from Coral Skeletal Carbonate by Hydrothermal Exchange

WE have prepared porous microstructures, having potential for prosthetic applications, consisting of hydroxapatite and of whitlockite, by employing exchange reactions at elevated temperatures and pressures. Rather demanding specifications are to be met by biomaterials being considered for tooth or bone replacement. Porous solids have the advantage of allowing circulation of body fluids and of increasing the potential for firm attachment of body tissue[1,2]. Weber *et al.*[3] successfully replicated the porous structure of echinoid skeletal material in epoxy resin and in sodium silicate; and White *et al.*[4] achieved replication of the coral *Porites* structure with methacrylate, tin, Tichonium, and sintered Al_2O_3. This was the starting point for our attempts to reproduce such structures in the phosphatic material which is a major component of human teeth and bones, hydroxyapatite. Such a material, porous, inorganic and sterile (formed at high temperatures and pressures), should be highly compatible with body tissue, and when used as bone implants may become essentially integral with the bone. Furthermore, composites of such porous hydroxyapatite with other materials including metals[4] may achieve optimum mechanical and physical properties for a particular application.

We anticipated that by choice of suitable experimental parameters it would be possible to replace with phosphatic material the porous calcium carbonate skeletal structure of some marine invertebrates. Hydroxyapatite $[Ca_{10}(PO_4)_6(OH)_2]$ is harder (Mohs hardness = 5) than either the aragonite (= 3.5–4) or calcite (= 3) forms of $CaCO_3$ and therefore such exchange has the potential to form structures which are stronger than the skeletal material of the original marine organism. It would, of course, have the advantage that it would be chemically and mineralogically 'identical' with normal human hard tissue, and would be stable in contact with body fluids, while the carbonate is not. High pressure and high temperature treatment would furthermore solve problems of sterilisation.

Slices of the massive scleractinian coral, *Porites*, and spines of the asteroid *Acanthaster planci* were used as starting materials to provide the aragonite and calcite polymorphs of $CaCO_3$, respectively. Hydrothermal techniques[5] were used, since it was expected that elevated temperatures and pressures would hasten any replacement process. The sections of *Porites* coral, or of the *Acanthaster planci* spine, together with weighed quantities of reactants and water were sealed in a gold tube, heated at specified temperatures and pressures for periods of time varying from 12 h to 1 week, cooled and the products examined.

Essentially complete replacement of aragonite by phosphatic material has been achieved under particular conditions. The porous interconnecting structures were preserved, as shown in the scanning electron micrographs of Fig. 1*a* and *b*. Figure 1*a* shows the material which is hydroxyapatite, having replaced the original *Porites* aragonite[4] and preserved its structure.

Typical experimental conditions for the exchange reaction to produce hydroxyapatite are given in Table 1, along with data on the asteroid material. Experiments resulting in replacement of the aragonite are listed and, for contrast, examples of less favourable conditions. We assume that under favourable conditions the following exchange reaction takes place.

$$\underset{\text{aragonite}}{10CaCO_3}+6(NH_4)_2HPO_4+2H_2O\rightarrow \underset{\text{OH-apatite}}{Ca_{10}(PO_4)_6(OH)_2}+6(NH_4)_2CO_3+4H_2CO_3$$

Observations under the polarising microscope are recorded as well; and phase identification was made by X-ray diffraction as well as observations under the microscope.

The *Acanthaster planci* spines were completely converted to whitlockite (β-$3CaO.P_2O_5$) as shown in Table 1 and Fig. 1*b*. For the formation of whitlockite, the previous reaction may be modified accordingly:

$$\underset{\text{calcite}}{3CaCO_3}+2(NH_4)_2HPO_4\rightarrow \underset{\text{whitlockite}}{2[Ca_3(PO_4)_2]}+2(NH_4)_2CO_3+2H_2CO_3$$

The microstructure of the whitlockite product is very close to that of the original carbonate skeletal material, shown by Weber *et al.*[3,4,6,7].

Some very tentative tensile strength data are given in Table 1, obtained on both the original coral aragonite, and on the hydroxyapatite product. The measurements were made on rectangular bars approximately 0.15 × 0.15 × 1 inch using the 4-point loading method. Whereas the strength measurements were not sufficient in number to be precisely determined, they indicate that the exchange products are generally as strong as or stronger than the original coral, and provide considerable encouragement for extension of the investigation.

The unit cell dimensions of two apatite samples were refined, using the thirteen strongest lines below $2\theta = 50.5°$ (Table 2).

There appears to be a real increase in cell volume, ~0.35%, over the reference values for CO_2-free OH-apatite crystallised at higher temperatures. The X-ray peaks are slightly broader than in hydroxyapatite crystallised hydrothermally at higher temperatures. Several effects may account for the cell increase: incorporation of CO_3^{2-}, a very small amount of Sr^{2+}, and possibly some NH_4^+, as well as the enlargement which is also observed in hydroxyapatites precipitated at low temperatures.

Semi-quantitative spectrographic analysis data for a typical

Holly Springs 9, 10*	9.426±0.001	6.884±0.001	529.7

* The two reference measurements made in our laboratory are of synthetic OH-apatite crystallised at 800° C, and of natural OH-apatite (containing impurities) from Holly Springs, Ga. (ref. 9).

Electron microprobe analyses for Ca : P ratio showed approximately the same value as for typical OH-apatites crystallised at higher temperatures, assumed to be stoichiometric.

Infrared absorption spectra taken of typical examples of the exchanged specimens reveal small absorption peaks due to the presence of CO_3^{2-} substituted in the hydroxyapatite structure. The CO_3^{2-} spectra appear to be explained as a composite of peaks at 884, 1,465, and 1,534 cm^{-1} and of peaks at 864, 1,430, and 1,455 cm^{-1}. This indicates that CO_3^{2-} substitutes both for OH^- in the columnar positions, and for tetrahedral PO_4^{3-} (ref. 8). Similar observations concerning infrared absorption spectra have been made by Eysel and Roy[9,10] in synthetic apatites produced in the same pressure-temperature range from chemical mixtures into which CO_2 has deliberately been introduced. These data suggest that there is a maximum concentration of CO_3^{2-} which may substitute for OH^- or PO_4^{3-} under a particular set of conditions.

The full explanation for the phenomenon observed, that hydroxyapatite was formed from aragonite-$CaCO_3$, while whitlockite was formed from calcite-$CaCO_3$ has not yet been found, and probably involves complexities of nucleation and crystal growth, as well as phase stability[11,12]. Indeed, two specimens of coral and spines sealed together in the same tube produced, respectively, hydroxyapatite and whitlockite. Calcite spines of *Acanthaster planci* are magnesium-rich[6], and magnesium is clearly associated with whitlockite: up to 17 atom % Mg has been found to substitute for Ca in whitlockite[13], while its solid solution in hydroxyapatite is very limited[17]. Naray-Szabo[14] pointed out that Mg^{2+} 'de-stabilises' the apatite lattice; examples are known of whitlockite (rather than hydroxyapatite) formation[15] in dental calculus in which there is positive correlation of whitlockite content with magnesium; and most whitlockite natural mineral deposits contain significant amounts of magnesium.

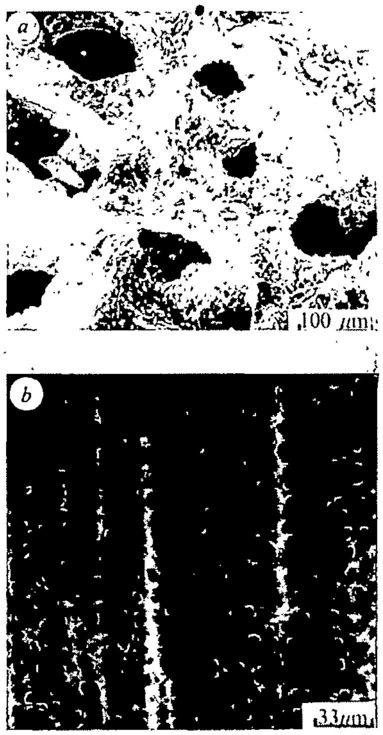

Fig. 1 *a*, Hydroxyapatite replacement of coral *Porites* structure; *b*, whitlockite replacement of *Acanthaster planci* spine, originally composed of high-magnesium calcite.

The major concern of the present work, however, is the exchange process by which the porous coral structure preserved as hydroxyapatite (containing some CO_3) is formed. There are

certain crystal structural similarities between aragonite and apatite, which obviously favour this morphological preservation[10].

The *Acanthaster* spines consist of single crystal calcite[7], which could result in ordered epitaxial growth of single crystal whitlockite. While the crystal structure of whitlockite is currently being worked out in detail (A. L. Mackay, reference in ref. 16; and refs 13, 17, 18), the fact that the external morphology is rhombohedral, similar to that of calcite, and its space group (R3c) is similar to that of calcite (R$\bar{3}$c), suggests the possibility of such structural control (D. M. Roy and D. Dinger, unpublished).

In conclusion, we have produced porous structures which have great potential for use in human implants, in the material which is the major inorganic component of tooth and bone, and which should be most readily accepted by the body, hydroxyapatite. The second phosphatic material produced, whitlockite, may also have potential for such applications. The hard tissue of the massive scleractinian coral, *Porites*, which was used as the starting material for producing the hydroxyapatite materials, exists in very large quantity, so there is essentially no limit on its availability. Furthermore, the conversion to hydroxyapatite was achieved at elevated temperatures and pressures, insuring more than adequate sterilisation, and preserving the original structure. Such porous materials when used in implants would permit circulation of body fluids, allowing firm attachment of living tissue, to enable regeneration as rapidly as possible

We thank Jon N. Weber and E. W. White for supplying the echinoderm and coral specimens, for critically reading the manuscript and for encouragement. E. Shull provided help with the mechanical measurements, and G. McCarthy with X-ray measurements. Equipment was made available by an ARPA contract and a grant from the National Science Foundation.

Non-electrolyte Probes of Membrane Structure in ADH-treated Toad Urinary Bladder

ALTHOUGH it is well known that antidiuretic hormone (ADH) increases the permeability of amphibian urinary bladders to water and small polar non-electrolytes such as urea and acetamide[1,2], there is much uncertainty about the mechanisms involved. To gain further insight into the interaction of ADH with this membrane, we have studied the permeation of lipophilic molecules in the presence and absence of the hormone. It has long been recognised that permeability measurements may offer unique clues about the nature of biological membranes[3,4].

Our approach was similar to that used previously to study non-electrolyte permeation across the gall bladder[5]. Urinary bladders from the toad (*Bufo marinus*) were mounted as flat sheets between two lucite chambers. The area of the window between the chambers was 1.3 cm^2, and each chamber contained 16 ml of saline. The composition of the saline was 104.5 mM NaCl, 2 mM KCl, 1 mM $CaCl_2$ and 1 mM $MgSO_4$ buffered at *p*H 7.4 with 2.125 mM Na_2HPO_4 and 0.375 mM NaH_2PO_4. The saline in each chamber was stirred vigorously with bar magnets, and was gassed with 100% oxygen. The electrical resistance of the urinary bladders ranged from 1,400 to 6,500 ohms cm^2 with a mean value of 2,600±70 (150) ohms cm^2. All experiments were carried out at room temperature (22°–24° C).

The permeability of lipophilic non-electrolytes, that is those with an oil/water partition coefficient greater than 1×10^{-3}, was determined by radioactive tracer techniques. A tracer quantity of the radioactive solute was added to the mucosal solution, and the rate of appearance of the isotope in the serosal solution was determined by withdrawing aliquots of the serosal solution at regular intervals. All radioactive samples were assayed by conventional liquid scintillation counting techniques. Permeability coefficients (*Ps*) were expressed in cm s^{-1}, and were corrected for unstirred layer effects whenever necessary[5].

Radioactive ^{14}C-isotopes were purchased from International Chemical and Nuclear Co., Irvine, California (1,4-butanediol, 1,2-propanediol, antipyrine, caffeine, 1,7-heptanediol, and 1,6-hexanediol), Amersham/Searle Corp., Arlington Heights, Illinois (nicotinamide) and American Radiochemical Corp., Sanford, Florida (n-butyramide and iso-butyramide).

For these non-electrolytes, the unidirectional fluxes reached a steady state within 1 h of addition of the isotope, and remained constant for at least 6 h. ADH ('Pitressin') was added to the serosal solution 2 h after the addition of the isotope to give a final concentration of 130 mU ml^{-1}. *Ps* of the untreated bladders were calculated from the fluxes during the hour before the addition of ADH, and the *Ps* in the presence of ADH were calculated from the fluxes measured in the hour following addition of the hormone.

In the absence of ADH the permeabilities varied from 12 ± 1 (8)$\times10^{-7}$ cm s^{-1} for nicotinamide to 290 ± 11 (6)$\times10^{-7}$ cm s^{-1} for caffeine. As anticipated, there was a linear relationship between the permeability coefficients of the lipophilic solutes and their olive oil/water partition coefficients: the slope of the line was 1, and the regression coefficient was 0.86. This indicates that the membrane, or membranes, controlling permeation across this epithelium are as hydrophobic as olive oil, and that the selectivity for both permeability and bulk phase partition coefficients is governed by the same basic intramolecular forces[4].

Addition of ADH caused a statistically significant increase in the permeation of all solutes across the bladder. The *Ps* for nicotinamide and caffeine increased to 23 ± 2 (6)$\times10^{-7}$ and 377 ± 0 (2)$\times10^{-7}$ cm s^{-1} respectively. The *Ps* for all nine non-electrolytes in the presence of ADH are plotted against those in the absence of ADH in Fig. 1. This shows that there is a linear relation between the permeabilities in the absence and presence of hormone; the slope of the line was 1.3, and the regression coefficient was 0.99. This leads to the conclusion that the hormone produces a generalised, but unselective, increase in the permeability of all the lipophilic compounds, that is the permeability of all the compounds increased by roughly the same factor, and there is no apparent change in the selectivity. (Similar changes in permeability were produced by the addition of ADH to the mucosal solution, but only in the presence of 0.5–1 mM $LaCl_3$. This suggests that the surface charge on the membrane surface is involved in the action of the hormone.)

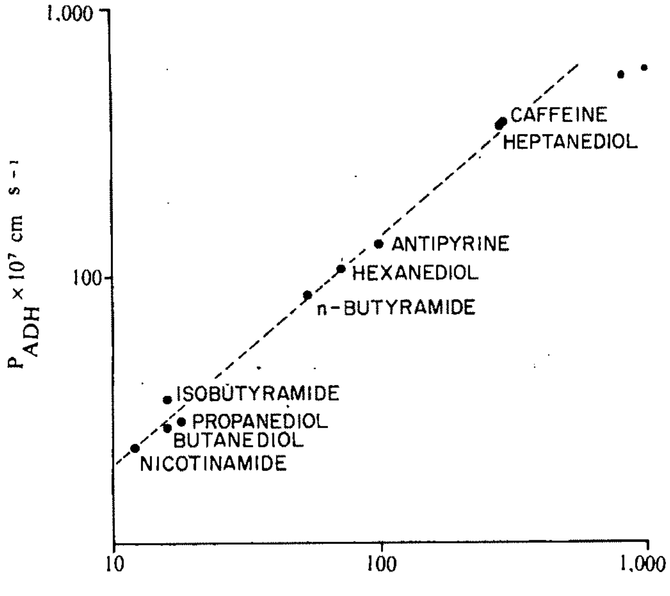

Fig. 1 The effect of ADH on the permeation of lipophilic solutes across the toad urinary bladder. Non-electrolyte permeability coefficients (cm s^{-1}) obtained in the presence of ADH (on the ordinate) are plotted against the coefficients obtained in the absence of the hormone (on the abscissa).

The effect of ADH on the permeability of the toad bladder to lipophilic solutes is much smaller than that obtained with hydrophilic solutes. For example, the permeabilities of urea, acetamide and water increased from 14 ± 1 (16)$\times10^{-7}$, 16 ± 1 (44)$\times10^{-7}$, and $1,300\pm80$ (56)$\times10^{-7}$ cm s^{-1} to 49 ± 8 (2)$\times10^{-7}$, 72 ± 16 (14)$\times10^{-7}$ and greater than $10,000\times10^{-7}$ (8) cm s^{-1} respectively.

Many biological membranes discriminate between branched and straight chain isomers[4]. Branched chain solutes are usually much less permeable than the straight chain isomers, and this has been attributed to the highly ordered configuration of the lipids in the cell membrane. In the toad bladder we find that in the absence of ADH the permeability of iso-butyramide is 16 ± 1 (20)$\times10^{-7}$ cm s^{-1}, whereas the permeability of n-butyramide is 54 ± 3 (20)$\times10^{-7}$ cm s^{-1}. This difference in permeability is strikingly similar to that for the permeation of the amides across red cell membranes[6] and gall bladder epithelium (unpublished observations). Thus it may be concluded that the lipids exist in a highly ordered configuration in the epithelial membranes of the toad urinary bladder.

The permeability of both isomers increased when ADH was added, but the increase obtained with iso-butyramide was much more dramatic than with the straight chain isomer. The permeabilities of iso-butyramide and n-butyramide increased to 35 ± 3 (8)$\times10^{-7}$ and to 68 ± 7 (8)$\times10^{-7}$ cm s^{-1} respectively. In paired experiments on tissues from the same animal, the ratio of the iso-butyramide to n-butyramide permeabilities increased from 0.30 to 0.51 when the membrane was treated with ADH. These results strongly suggest that the branched molecule encounters less steric hindrance in permeating across ADH treated membranes than in control membranes. This leads to the conclusion that ADH increases the permeability of the toad urinary bladder epithelium by increasing the fluidity of the cell membranes.

In biological and artificial membranes it has been reported previously that increases in membrane fluidity are associated with positive increments in non-electrolyte permeation[7–10]. Furthermore, recent studies of liposomes showed that when the hydrocarbon tails of the membrane lipids passed from a fluid into a crystalline state, there was a decrease in the partition of solutes into the membrane[11–14]. This suggests that ADH effects in the toad bladder epithelium result from an increase in the partition of solutes into the plasma membranes, but changes in solute mobility cannot be excluded.

It is now recognised that the partition of solutes into biological and artificial membranes probably varies with position in the membrane; lipophilic solutes are expected to be partitioned mainly into the hydrocarbon core of the membrane, whereas hydrophilic solutes are probably located nearer the polar head groups of the lipids[13]. Consequently, changes in fluidity of a membrane could produce quantitatively different effects on lipophilic and hydrophilic solutes. If, for example, ADH caused a relatively larger increase in the fluidity at the periphery than in the core of the bladder membranes, there should be a greater increase in the permeation of hydrophilic solutes than lipophilic solutes. Such an effect may, at least partially, account for the quantitative difference between the effect of the hormone on small polar solutes and lipophilic solutes. This hypothesis could be tested by measuring the effect of the hormone on the partition of solutes into isolated plasma membranes of the toad bladder.

It is still not certain whether or not ADH acts on the apical cell membrane of the toad bladder epithelium directly, or through some intracellular mediator. Evidence for a direct effect on the apical membrane, at least for non-electrolyte permeability, is that (i) vasopressin increases the osmotic water permeability of artificial bilayer membranes, whereas cyclic AMP does not[15–17], and (ii) ADH in the mucosal solution increases the permeability of the toad bladder when the surface charge on the outer surface of the apical membrane is screened with polyvalent cations.

In conclusion, we have shown the ADH increases the permeability of the toad urinary bladder to lipophilic solutes, in addition to the effect on small polar solutes and water. This increase in permeability is associated with an increase in the fluidity of the membrane, or membranes, controlling permeation across the epithelium. Evidence is cited to suggest that the change in configuration of membrane lipids acts to increase the partition of solutes into the membrane, and that quantitatively different effects are expected for lipophilic and hydrophilic solutes. These experiments emphasize that a direct interaction of the ADH with the membranes of the toad urinary bladder may account for at least some effects of this hormone. Further clues will undoubtedly come from experiments designed to evaluate the effect of ADH on permeability of the apical membrane of the epithelium.

We thank Drs N. Bindslev and J. M. Diamond for comments on the manuscript. This study was supported by grants from the US Public Health Service.

Melatonin stimulates Growth of Brown Adipose Tissue

IN small mammals brown adipose tissue (BAT) is an important site of non-shivering heat production[1,2]. Its mass increases during cold adaptation together with the ability to produce heat (ref. 3 and G. H., unpublished), thus improving cold tolerance[4]. In the golden hamster, Hoffman *et al.*[5] also found an increase of BAT weight following exposure to short photoperiods. The pineal hormone melatonin has been shown to affect photoperiodic responses (ref. 6, and K. H. and G. H., unpublished), and therefore an action of melatonin on development of BAT seemed likely. In this study, the effect of short photoperiods and of melatonin on the amount of BAT was investigated in the Djungarian hamster *Phodopus sungorus*. This species shows a marked annual cycle of testis size and activity, body weight, and coat colour when kept under natural light conditions[7], and all of these functions can be influenced by manipulation of the photoperiod (ref. 6, and K. H. and G. H., unpublished). The species does not hibernate, but may show daily torpor in winter, while the gonads are regressed even at room temperature[7].

Fifty adult male hamsters (average body weight 42 g) that had been kept under natural light conditions and temperatures of 20±3° C were exposed to either long (16 h light d^{-1}) or short (8 h light d^{-1}) artificial photoperiods at 20±1° C starting in July. The animals were housed singly. Nine hamsters in either condition were implanted with tablets of one part melatonin in ten parts beeswax (average weight of implants 34 mg) subcutaneously six times at weekly intervals. Each tablet thus contained about 3.1 mg of melatonin but control experiments showed that only a small fraction of this was absorbed[6]. Control animals in each light condition were either left untreated (seven hamsters each), or received implants of beeswax only (nine hamsters each). After 64 d under artificial light conditions, the hamsters were killed, weighed, and stored in a deep freeze until dissection. Drying was prevented by wrapping each animal in a plastic bag. Body weight was again checked before removal of BAT and no decrease resulting from storage was found. BAT was carefully dissected from the interscapular, subscapular, dorsal, cervical, suprasternal, subvertebral and other intrathoracal sites and was weighed immediately after dissection. No BAT was taken from the perirenal region.

The weight of BAT thus determined is given in Fig. 1 for all hamsters. To eliminate the effect of differences in body weight, weight of BAT was calculated as a percentage of body weight. Control hamsters kept the 8 h photoperiod contained nearly 50% more BAT than those kept in the 16 h photoperiod ($P<0.001$; t test). Hamsters that had received melatonin had the highest amount of BAT; on the average it was more than 5% of body weight. In both photoperiods, BAT mass of hamsters treated with melatonin differed significantly from that of the respective controls ($P<0.001$). No difference in BAT content was found in the two groups receiving melatonin but kept in different photoperiods.

The finding that the controls contained significantly higher amounts of BAT after exposure to short photoperiods confirms results obtained in the golden hamster[5], and shows that seasonal increase in BAT mass in winter is not simply a consequence of cold exposure, but can also result from the short photoperiod at that season.

The drastic increase of BAT mass in hamsters treated with melatonin indicates that the pineal may be involved in its regulation. The pineal has been shown to participate in the regulation of seasonal cycles by light[8,9]. In mammals, melatonin is exclusively produced in the pineal, and the activity of hydroxyindole-O-methyltransferase, the enzyme responsible for the last step in melatonin formation, has been reported to be light dependent, showing high activity in darkness and low activity in light[8]. Our data demonstrate a drastic effect of melatonin on growth of BAT, and it seems reasonable to assume that the rise in BAT content in hamsters kept in short photoperiods might be mediated by increased production of melatonin in the pineal in these conditions. As no difference in BAT was found between the two photoperiods in the hamsters treated with melatonin, and as the amount was nearly twice that found in the controls in short photoperiods, one might speculate that the amount of melatonin effective in our experiments already instigated the maximal possible growth of BAT, and that therefore no additive effects of photoperiod could be observed. This assumption is supported by the fact that the amount of BAT found in our experiments after melatonin treatment is higher than nearly all previously reported values[1].

The pathway by which melatonin acts on the growth of BAT is unknown. Melatonin has been claimed to be the antigonadotrophic hormone of the pineal[8] but contradictory results have been obtained after its administration[9,10]. In *Phodopus*, extraneously administered melatonin delayed the accelerating effect of long photoperiods on testis development, increase of body weight, and change into summer coat in midwinter, but did not completely suppress such development[6]. In summer, melatonin suppressed or greatly diminished the effect of short photoperiods which in untreated controls caused testicular involution, decrease of body weight, and change into winter coat (K. H. and G. H., unpublished). In the experiments reported here, however, melatonin caused enlargement of BAT independent of photoperiod. Thus, its action does not parallel that on the

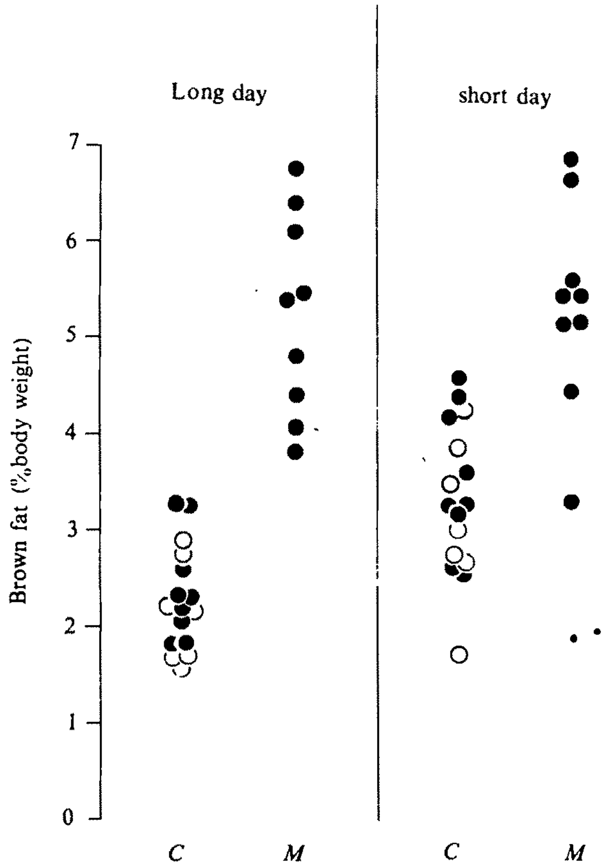

Fig. 1 Weight of brown adipose tissue (BAT) as percentage of body weight in the Djungarian hamster *Phodopus sungorus*. Each point represents BAT weight of a single hamster. *M*, Hamsters treated with melatonin; *C*, controls without any treatment (○) and implanted with plain beeswax (●). Mean ±s.e.: long day, *C*, 2.30±0.13; *M*, 5.24±0.35; short day, *C*, 3.34±0.20; *M*, 5.33±0.36. Long day, 16 h light; short day, 8 h light.

other functions showing seasonal variations, and must be brought about by different pathways.

The physiological mechanism controlling development of BAT during cold adaptation is not resolved. There are indications that thyroxine and noradrenaline are involved in stimulation of BAT growth because, in rats, an increase in BAT mass was observed after repeated injections of thyroxine and/or noradrenaline[4]. Blocking the thyroid activity in mice by feeding them with propriothiouracil caused a reduction in the amount of BAT (G. H., unpublished). In young rats, growth of BAT was stimulated by injections of cortisone[11]. Little is known about the effects of melatonin on the adrenal cortex, but it has been reported to inhibit thyroid function, though the results are far from uniform[8,12]. As melatonin stimulated BAT growth in our experiments it does not seem to act by way of the thyroid. A direct effect on BAT growth or a completely different pathway seems more likely.

The action of melatonin on growth of BAT described here is, to our knowledge, the first evidence that the pineal may be involved in thermoregulatory adjustments in mammals.

Transmission of Mammalian Piroplasm by an Argasid Tick

IT is the accepted view that parasites belonging to the suborder Piroplasmidae Wenyon, 1926, are exclusively transmitted by "hard" ticks belonging to the family Ixodidae Murray[1,2]. Most piroplasms of domestic animals have more than one Ixodid vector. In the laboratory, small mammal piroplasms belonging to the genera *Babesia* Starcovici, 1893, and *Nuttallia* Franca, 1910, are used as models for the diseases caused by piroplasms of domestic animals. This research, however, suffers from the drawback that the parasites cannot be biologically transmitted, except in two cases. Thus, *Babesia rodhaini* Van den Berghe, Vincke, Chardome and Van den Bulcke, 1950, a rodent piroplasm very commonly used in laboratory investigations, has no known vector; nor has *Babesia hylomysci* Bafort, Timperman and Molineux, 1970. The two small mammal piroplasms of which the vectors are known are *Nuttallia microti* Coles, 1914, and *Nuttallia danii* Tsur, Hadani and Pipano, 1960 (and the probably identical *N. tadzhikistanica* (Krylov and Zanina, 1963), Krylov, 1964). The vectors of these piroplasms are *Ixodes trianguliceps*[3] Birula, 1895, for the former, and three species of *Hyalomma* and two species of *Rhipicephalus*[4] for the latter. All of these vectors belong to the Ixodidae.

Nuttallia meri Gunders, 1971, was isolated from the fat sand rat *Psammomys obesus* Cretzchmar, 1828, from the lower Jordan Valley[5] and, though having a narrow range of infectivity for laboratory animals, is considered a potential model for the study of piroplasmosis of economic importance. The search for possible tick vectors in nature led to the discovery, within *Psammomys* burrows, of the "soft" tick *Ornithodoros erraticus* (Lucas, 1849) (small race) which had not previously been reported from Israel[6]. No other ticks were found in this biotope.

We have reported elsewhere[7] failure to transmit *N. meri* through clean laboratory-raised *Hyalomma excavatum* Koch, 1844, *Rhipicephalus sanguineus* (Latreille, 1806) and *Ornithodoros tholozani* (Labulbène and Megnin, 1882), but successful infection of clean laboratory-bred, splenectomised, *Psammomys* (HUPO strain) followed intraperitoneal injection of triturated field-collected *O. erraticus*. Further, one laboratory-bred *Psammomys* became infected with *N. meri* after eleven adult ticks were fed on it. The ticks had been collected in the field 2 d earlier. Although there had been a lapse of only 2 d between field collection and biting by the ticks, it was clear that this was true transmission, as the ticks had to be starved to be ready to feed.

The purpose of this communication is to report three further instances of transmission of *N. meri* to *Psammomys* by the bite of *O. erraticus* up to 81 d after field collection of the ticks. All three sand rats were of the Hebrew University strain of *Psammomys obesus*, were laboratory bred and were splenectomised before having ticks fed on them. Four nymphs and three imago *O. erraticus* that had been collected in the field 39 d earlier were fed on the first *Psammomys*. Parasitaemia became apparent on day 17. Eight adult *O. erraticus* and one nymph were fed on the second sand rat 81 d after their collection. The sand rat became manifestly infected on day 17. A pool of starved ticks were fed on the third *Psammomys*. The ticks included some that had infected the first *Psammomys* on day 39 after collection and others that had been found to be uninfected. Again, transmission of *N. meri* occurred and was observed on day 12, indicating that a batch of ticks may infect more than once and that the parasite persists in the ticks, even after a blood meal, for at least 81 d.

The four instances of transmission, by bite, of *N. meri*, through field-collected *O. erraticus* clearly establish this tick as a natural vector of this parasite. This is the first proven example of transmission of a mammalian piroplasm by an Argasid ("soft") tick. The reports by Rastegaïeff[8] and Bitukov[9] suggesting that *Theileria* (=*Gonderia*) *ovis* (Rodhain, 1916) Lestoquard, 1929, was transmitted through *O. lahorensis* Neumann, 1908, are considered doubtful by Neitz (ref. 1 and personal communication) because of the excessively short incubation periods following tick bite (3 and 8 d, respectively) and because the sheep and goats had not been shown to be free of naturally acquired infection before their use as experimental animals.

The demonstration that an Argasid tick, *Ornithodoros erraticus*, could transmit, by bite, a mammalian piroplasm (*N. meri*) suggests that, for those small mammal piroplasms for which no natural vector is as yet known, a search among the soft ticks may be rewarding.

Carnosine in Nucleated Erythrocytes

IN the course of studies of the metabolism of intracerebrally administered L-U-^{14}C-histidine in brains of mice and frogs (*Rana pipiens*), analyses were also performed on blood samples from the injected animals. The mice received 1.5×10^6 c.p.m. of the labelled histidine, and 1 h later samples of blood were taken by means of orbital puncture. Frogs were injected with 2.9×10^6 c.p.m. and blood was obtained after 1 h by cardiac puncture. The samples were deproteinised in 5 volumes of 0.4 N perchloric acid and processed in the manner described previously for brain and tumour tissues[1]. Aliquots of neutralised extracts were electrophoresed on Whatman No. 3 paper at *p*H 10.0 together with known standards of carnosine, homocarnosine, histidine, imidazoleacetic acid, N-acetylhistidine, and histamine; and stained with Fast Red B in the manner described previously[1].

Scanning the electropherograms showed only a few very minor radioactive peaks, which were not investigated further, but a marked enhancement of the size of the carnosine marker spot was noted in the extracts of frog blood. Electrophoresis without added markers showed a strongly diazo-positive material to be present in the carnosine position in extracts of frog blood, and subsequent experiments showed it to be largely located in the erythrocytes. Electropherograms of mouse blood were negative.

When neutralised perchloric acid extracts of frog erythrocytes were subjected to two-dimensional thin-layer chromatography (TLC) (ref. 2), the major diazo-positive substance migrated to a position corresponding to that of carnosine (Fig. 1). In addition, there was a small amount of material corresponding in position to N-acetylhistidine on the chromatograms. We have shown previously that, in the frog, intracerebrally injected histidine is converted extensively into N-acetylhistidine[1]. When the frog erythrocyte extracts were chromatographed with histidine, carnosine, homocarnosine and N-acetylhistidine (Fig. 2), it became apparent that the unknown material was probably carnosine. Material containing the compound was then isolated from one-dimensional TLC plates[2] and a portion was hydrolysed at 110° C in 6 N HCl for 20 h as shown by two-dimensional TLC (ref. 2) of equal aliquots of hydrolysed and unhydrolysed samples. Disappearance of the original material and liberation of β-alanine and histidine were noted on hydrolysis (ref. 2).

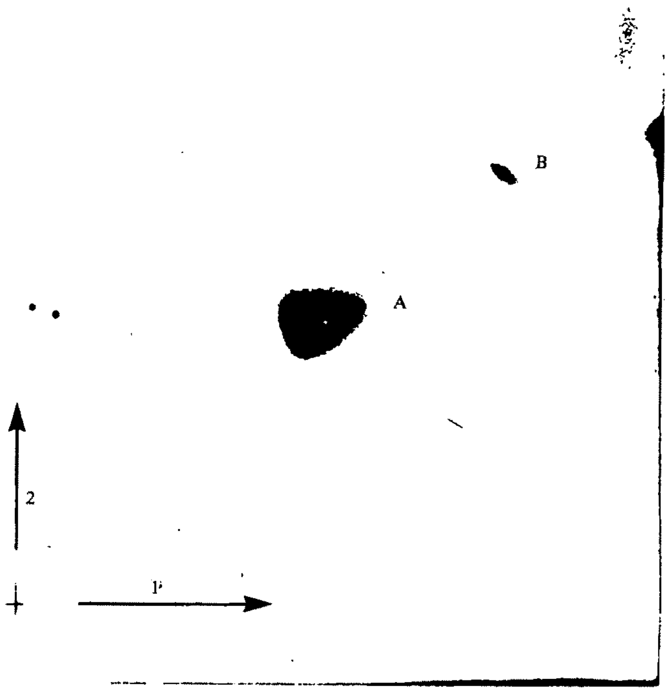

Fig. 1 Two-dimensional TLC on silica gel[2] of extract corresponding to 20 µl of packed frog erythrocytes. The chromatogram was run in the first dimension (1) in ethanol : ammonia (28%) : water (70 : 5 : 25) and in the second dimension (2) in chloroform : methanol : ammonia (28%) : water (30 : 60 : 5 : 15). Spot A occurs in a position characteristic for carnosine, and spot B for N-acetylhistidine[2].

Analysis of the above samples by column chromatography on a Beckman amino acid analyser showed there to be 38 nmol of histidine and no β-alanine in unhydrolysed extract corresponding to 1 ml of packed erythrocytes, while after hydrolysis 116 nmol of histidine and 92 nmol of β-alanine were found. Thus, histidine and β-alanine were liberated in approximately isomolar amounts on hydrolysis, confirming the identity of the diazo-positive material with carnosine.

Employing the above techniques, carnosine has been detected in erythrocytes of White Leghorn chickens, but in smaller quantities than in the frog. To date we have not

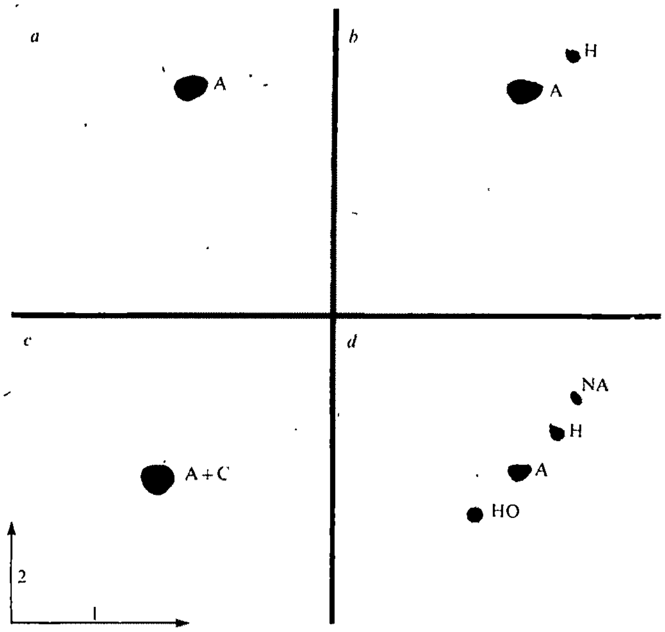

Fig. 2 Two-dimensional TLC of equal amounts of isolated spot A with and without markers run in the same manner as in Fig. 1. Chromatograph *a*, spot A alone; *b*, histidine added; *c*, carnosine (c) added; *c*, together with homocarnosine (HO), histidine (H), and N-acetylhistidine (NA). Solvent system same as for chromatograph of Fig. 1.

been able to detect carnosine in concentrated extracts of mouse erythrocytes.

To our knowledge, carnosine has not been detected previously in erythrocytes of any species. Our results here show the presence of this dipeptide in relatively large amounts in frog erythrocytes and in smaller amounts in chicken erythrocytes, although it was undetectable in mouse red blood cells. Meaningful suggestions about the source or function of carnosine in nucleated erythrocytes cannot be made until much further work is accomplished. Although the presence of carnosine in muscle has been known for over 70 years[3], its function is still largely shrouded in mystery.

Association of Methionine Requirement with Methyl Mercury Resistant Mutants of Yeast

It has been known for several years that strains resistant to mercury can be obtained in several bacterial species[1–4]. Soon after the correlation between resistance to antibiotics and to mercury was recognised[2,5], it was established that genetic elements conferring resistance to antibiotics, mercury and other heavy metals in *Escherichia coli* and *Salmonella typhimurium*[6] and *Staphylococcus aureus*[7,8] reside on extrachromosomal resistance transfer factors or plasmids. Among fungi, mercury resistant strains of *Botrytis cinerea*[9], *Penicillium notatum, Sclerotinia fructicola, Stemphylium sarcinaeforme*[10], and *Saccharomyces cerevisiae*[11,12] have been reported. In most cases[1,3,9–12], this was accomplished by 'training' the normal strains for growth on media supplemented with successively increasing concentrations of mercury compounds, and in some cases[10] the resistance was lost when subcultured on mercury-free media. It is noteworthy that in none of the mercury-adapted strains of fungi has the genetic basis of resistance been determined. In this report we describe a method of isolation and characterisation of methyl mercury resistant mutants of *S. cerevisiae*. This study was undertaken with the view that the examination of physiological changes associated with genetically defined resistant mutants will be useful in studying the mechanisms of cellular detoxification of organic mercurials.

We used the following simple technique as the most efficient means of isolating spontaneous and induced methyl mercury resistant mutants. Fresh stationary phase cultures of haploid strains in YPD medium (1% Bacto-yeast extract, 2% Bacto-peptone, 2% dextrose) were washed and treated with 3% ethyl methanesulphonate for 1 h at 30° C. From 5×10^6 to 1×10^7 treated cells were spread on each dish of minimal agar medium (0.67% Bacto-yeast nitrogen base without amino acids, 2% dextrose and 1.5% agar) supplemented only for the nutritional requirement of the original strains. Sterile paper strips or disks were placed in the middle of the plates on which 30 to 60 nmol (100 to 200 μl of a 3×10^{-4} M solution) of methyl mercury chloride (K and K Laboratories, Plainview, New York) was dispensed. The cells were thus exposed to a continuous concentration gradient of methyl mercury. The plates were incubated at 30° C for 7–10 d. Cells could grow into a confluent lawn at the edge of the plate where the methyl mercury concentration was low and not inhibitory, but they could not grow near the impregnated paper. Occasionally a few colonies appeared in a region where the methyl mercury concentration was inhibitory to most cells. These colonies were isolated as presumptive resistant mutants and tested further. We have also isolated spontaneous and ultraviolet light-induced mutants by this method.

When colonies selected for methyl mercury resistance were analysed, most of them would not grow on minimal medium with or without methyl mercury and with the supplements necessary to satisfy the nutritional requirement of the parent strain. Further tests revealed that these mutants had become auxotrophic for methionine. It should be noted that the selection medium did not contain methionine. Furthermore, the addition of methionine to the selection medium resulted in a marked decrease of methyl mercury resistant mutants.

Eight mutants were crossed to normal strains, the diploid cells were sporulated, and genetic analysis was performed on the resulting meiotic segregants by standard procedures. In all eight cases, the methionine requirement segregated in the manner expected of a single chromosomal gene.

We then performed complementation tests with all pairwise combinations of the eight mutations. From this and from analysis of crosses among the mutants, it was established that all eight were allelic mutations. To determine whether the genetic lesions responsible for the requirement of methionine in the methyl mercury resistant strains arose at one of the previously identified genes concerned with methionine biosynthesis or whether they occurred at a previously undetected locus, complementation tests were carried out between this *met* gene and the standard methionine tester strains obtained from the Yeast Genetics Stock Center, University of California, Berkeley. These *met* mutants complemented mutants in all the previously identified *met* genes represented in the stock collection, *mes1, met1, met2, met4, met5, met6, met7, met8, met10, met13,* and *met14,* as well as *met3* which was isolated in our laboratory. (As far as we know, the *met9, met11* and *met12* mutants do not exist or represent alleles of some of the above loci (see refs 13 and 14).) To rule out the possibility of interallelic complementation between our *met* mutations and any of the other known *met* genes, a methyl mercury resistant strain was crossed to each of the methionine testers individually. Tetrad analyses of spore clones from these crosses showed that the *met* mutations in our strains segregate independently of all available previously known genes involved in methionine biosynthesis. We have designated this new locus *met15*.

We could not demonstrate resistance by comparing growth of the normal strain and *met15* strains on media containing various concentrations of methyl mercury or containing gradients of methyl mercury. Perhaps the differences are too slight to be revealed by these methods. The resistance of *met15* strains to methyl mercury, however, can be unequivocally shown by a reconstruction experiment (Fig. 1).

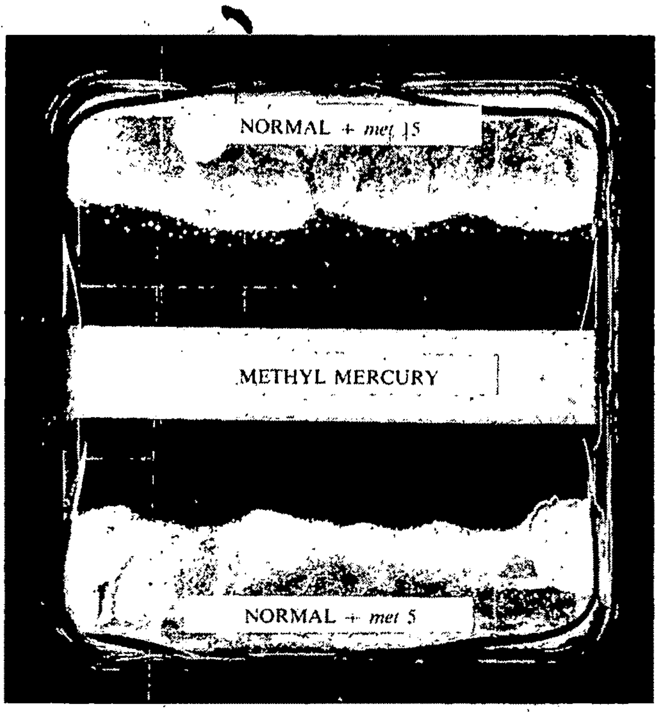

Fig. 1 Methyl mercury resistance of *met15* strains. The upper half of the plate was spread with approximately 2×10^6 cells from a mixed suspension of normal +*met15* strains and the lower half with 2×10^6 cells from a suspension of normal +*met5* strains. The ratio of normal to *met* cells in both cases was about 1,000 : 1. The paper strip in the middle was impregnated with 100 µl of 3×10^{-4} M solution of methyl mercury chloride. The photograph was taken after 7 d of incubation at 30° C. The methyl mercury resistant colonies of the *met15* strain (upper) can be seen growing before the front of the lawn of the normal strain.

The normal strain AS2–2C (α *leu2–1*) and the mutant S4 (α *leu2–1 met15–4*) obtained from AS2–2C were grown separately, washed and mixed. In addition a mutant S46 (α *leu2–1 met5*), directly isolated by replica plating techniques from AS2–2C, was similarly grown and mixed with the normal strain. The two kinds of mixed populations, as described in the figure legend, were plated on minimal agar medium supplemented only with leucine and exposed to methyl mercury. Only in the section of the plate seeded with normal+*met15* cells did any resistant colonies appear. These colonies could be isolated and analysed further. In one such reconstruction experiment 154 of the 164 isolated colonies carried the *met15* gene, and more importantly, 149 of the 154 *met15* colonies carried the input allele, *met15–4*. The remaining five were apparently new mutations at the *met15* locus. The frequency of recovery of the input *met15* strain was markedly reduced if the experiment was done on a medium supplemented with leucine and methionine. In the experiment described above, only fourteen *met15–4* colonies could be recovered from the medium containing leucine and methionine. Thus methionine inhibited the expression of resistance, a phenomenon corroborated by the decrease in mutation frequency on methionine-supplemented medium.

An interesting property of the resistant mutants was uncovered when we examined the interrelationship between methyl mercury resistance and methionine auxotrophy by growing the mutants on double gradient plates of methyl mercury and methionine (Fig. 2). The gradients were generated by adding the methyl mercury and methionine on paper strips which were placed at right angles to each other along the edges of the plates. Figure 2 shows growth patterns of S4 (α *leu2–1 met15–4*) and S46 (α *leu2–1 met5*). As noted earlier, the two strains are isogenic except for their *met* genes. The methionine auxotroph (*met15*), which is resistant to methyl mercury, has a growth pattern very different from the other methionine auxotroph (*met5*). We have so far compared the growth patterns of five different *met15* mutants with those of controls consisting of strains carrying mutations at *met5, met8* or *met10* locus, but otherwise isogenic to the *met15* strains. In every case, the *met15* strain showed the growth pattern depicted in Fig. 2*a*, whereas the control exhibited the pattern represented in Fig. 2*b*. We interpret the peculiar growth response of *met15* strains on the double gradient plates to indicate that at a critical concentration of methyl mercury the methionine requirement of the *met15* mutants is partially or completely alleviated. It also appears from the growth pattern on the *met5* plate that methionine at higher concentrations may be preventing methyl mercury toxicity.

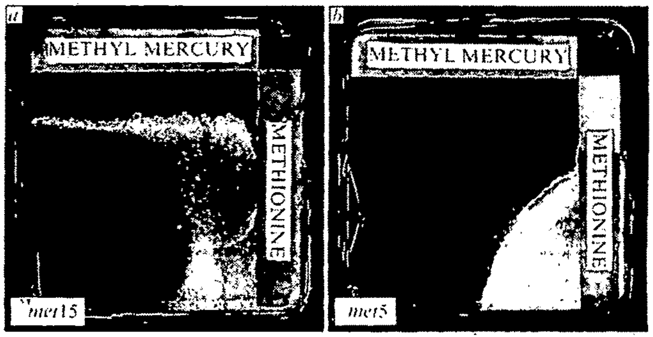

Fig. 2 Growth patterns of a *met15* (*a*) and a *met5* (*b*) strain on double gradient of methyl mercury and methionine. Approximately 1.3×10^6 cells per plate were spread uniformly over the whole area of the plates which contained minimal agar medium supplemented with leucine; 100 µl of 3×10^{-4} M solution of methyl mercury chloride and 200 µl of 1.6×10^{-2} M solution of methionine were used on the respective strips. The photographs were taken after 8 d of incubation at 30° C. The protruding area of growth of the *met15* strains indicates that the methionine requirement was completely or partially alleviated at certain concentrations of methyl mercury.

The data so far are consistent with the following interpretation of the interrelationship of methionine requirement and methyl mercury resistance. We hypothesise that a compound involved directly or indirectly in the biosynthesis of methionine can cause detoxification either by the formation of a complex with methyl mercury or by conversion of it to a volatile product. This compound accumulates in *met15* mutants and inhibits methionine biosynthesis. The diminution of the methionine requirement of the resistant mutants in the presence of methyl mercury may then be explained by the destructive action of methyl mercury on this compound. Methionine may inhibit the production of this compound by repression or feedback inhibition which would explain the poor expression of the resistance in the presence of methionine. These yeast mutants do not seem to detoxify methyl mercury by the same mechanisms found in other mercury resistant organisms[15–18]. We are continuing the investigation in the hope of explaining the results at molecular level as well as to test our working hypothesis.

This study was supported by grants from the US National Science Foundation and the US Atomic Energy Commission.

Free and Occluded Virus, similar to *Baculovirus*, in Hepatopancreas of Pink Shrimp

VIRUSES or virus-like particles have been reported infrequently from cells of estuarine and marine organisms[1–4]. Herpes-type viruses were described from an estuarine fungus[3] and oysters[4]. Helical or rod-shaped viruses have not been reported from most aquatic invertebrates, although rod-shaped virus-like particles were reported from a microannelid[5] and aquatic beetle[6].

Recently, I observed rod-shaped virus particles and related inclusion bodies in cells of pink shrimp (*Penaeus duorarum*) that were experimentally exposed to the polychlorinated biphenyl (PCB), Aroclor 1254. This report describes these particles and demonstrates their similarity to certain non-inclusion viruses and to nuclear polyhedrosis viruses of the *Baculovirus* group previously described only from insects and mites[6–10].

Adult pink shrimp, from the Gulf of Mexico near Cedar Key, Florida, were kept in flowing seawater and exposed to 3–5 μg l^{-1} PCB for 30–52 d as described elsewhere[11]. Control shrimp from the same stock were maintained in PCB-free flowing seawater. Non-experimental pink shrimp which were collected periodically from near Cedar Key and Pensacola, Florida, and prepared immediately for cytology are considered here as feral or wild shrimp. Hepatopancreatic tissues from forty exposed shrimp, forty control shrimp and fifty feral shrimp were fixed for histology in Davidson's fixative[12], sectioned and stained with Harris haematoxylin and eosin, mercury bromophenol blue or the PAS method.

Hepatopancreatic tissues from five exposed, five control and ten feral shrimp were fixed for electron microscopy

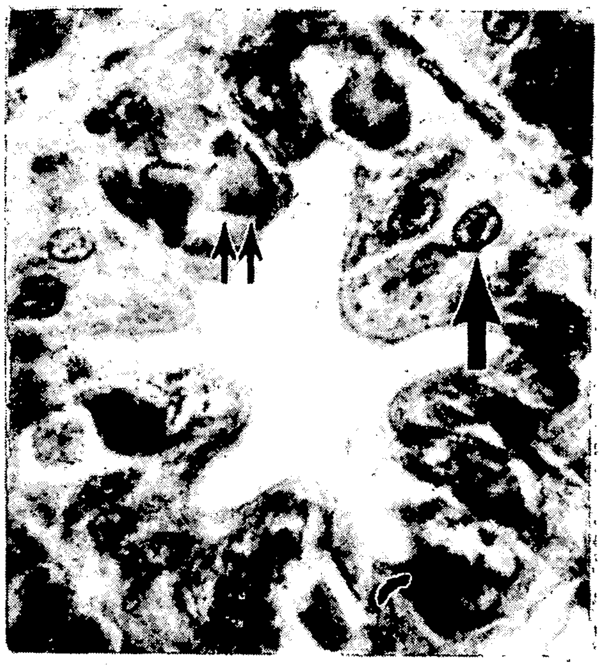

Fig. 1 Light micrograph of cross section of hepatopancreatic tubule from pink shrimp exposed to PCB; note normal nucleus of epithelial cell (one arrow), and crystalloid, tetrahedral inclusion bodies in hypertrophied nucleus of affected cells (two small arrows).

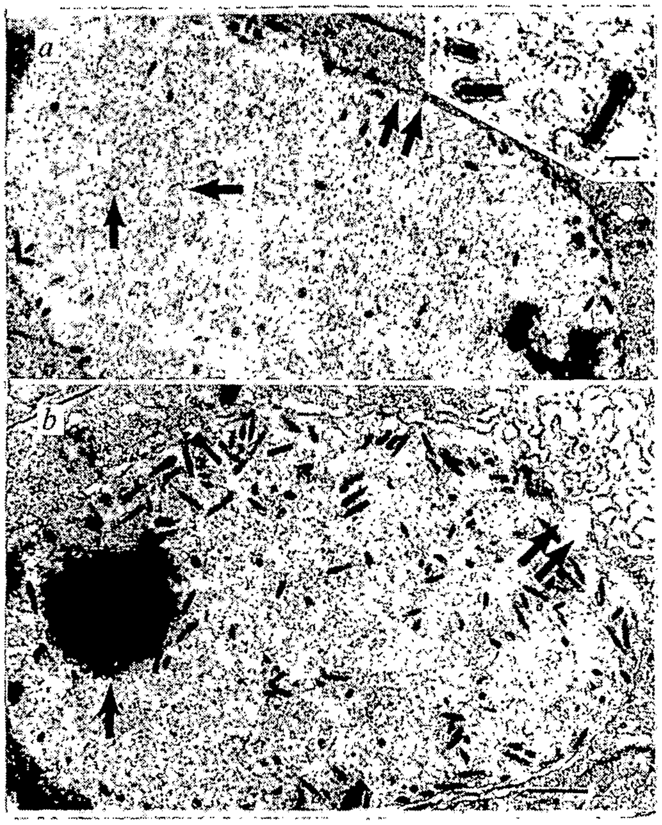

Fig. 2 *a*, Hypertrophied nucleus in epithelial, absorptive cell from hepatopancreas of shrimp exposed to PCB; non-occluded rod-shaped virions in longitudinal and cross section; single arrows point to intranuclear membranes associated with early virion formation, double arrows indicate abnormal multilaminate nuclear envelope. Inset: high magnification of rod-shaped virion in nucleus (bar=0.1 μm); note single envelope surrounding nucleocapsid. *b*, Moderately heavily affected nucleus; virions distributed mostly around inner periphery of nucleus; arrow points to degenerate nucleolus; double arrows point to envelope membranes entering the cytoplasm. Note many free ribosomes in cytoplasm (bar=1 μm).

(2.5% glutaraldehyde and 1% osmium) and embedded in Epon 812. Sections 50–100 nm thick were cut, collected on unsupported 300 mesh copper grids and stained with uranyl acetate and Reynold's lead citrate according to the short method of Hayat[13]. Approximately 3,000 hepatopancreatic cell profiles from feral and control shrimp and 1,500 hepatopancreatic cell profiles from exposed shrimp were examined with the electron microscope.

Light microscopy of fresh squashes and fixed, stained hepatopancreatic tissues of control shrimp revealed normal histological and cytological structure. Thirty per cent of shrimp exposed to PCB, and approximately 20% of feral shrimp from near Cedar Key, however, had crystalloid inclusion bodies in distorted, hypertrophied nuclei of hepatopancreatic epithelial cells (Fig. 1). These nuclear inclusion bodies were usually tetrahedral (pyramidal) in form in fresh squashes and triangular in sections. They ranged in size from 0.5 μm to 12 μm from base to point, and stained light blue with mercury bromophenol blue, and were PAS-negative.

Electron microscopy demonstrated normal ultrastructure of hepatopancreatic tubule cells and nuclei in feral and control shrimp. However, approximately 8% of the nuclear profiles of hepatopancreatic tubule cells from three PCB-exposed shrimp were hypertrophied, and contained rod-shaped, free (non-occluded) and occluded virions (Figs 2–4). Light microscopy showed that these exposed shrimp had numerous tetrahedral, crystalloid inclusion bodies in nuclei of hepatopancreatic cells.

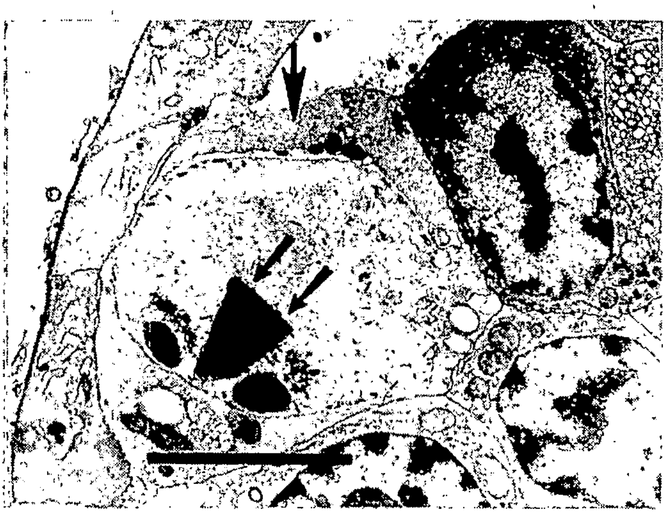

Fig. 3 Low magnification electron micrograph of section through hepatopancreatic tubule from exposed shrimp Note profile of epithelial cell and nucleus (one arrow) containing free virions and intranuclear, crystalline occlusion body (two arrows); note hypertrophy of affected nucleus (bar=5 μm).

A typical free virion within a cell nucleus consisted of a rod-shaped, electron-dense nucleocapsid surrounded by an electron-lucid area' enclosed by one or two envelopes (Figs 2*a*, inset, 2*b* and 5). Nucleocapsids varied in length (from 210 to 316 nm; average 288±31 nm, $n=30$) but had a relatively narrow range of diameters (from 44 to 64 nm; average, 59 nm±6 nm, $n=30$). In cross section, the average diameter of nucleocapsids plus their containing envelopes was 75 nm±7.5 nm ($n=30$). The envelopes surrounding the nucleocapsids (Fig. 5) seemed to be membranous with spatial and structural relationship to the nucleocapsid similar to that of envelopes in nuclear polyhedrosis virus (a *Baculovirus*) from *Bombyx mori*[9].

Virions were distributed in most nuclei in greater numbers near the inner nuclear membrane (Fig. 2*a* and *b*); however, they were associated with or occluded in crystalline bodies at the ultrastructural level in some nuclei (Figs 3 and 4). These crystalline, occlusion bodies were always triangular in section, paracrystalline in structure, and were the only structures observed with the electron microscope that could be related to the intranuclear, tetrahedral, crystalloid bodies observed by light microscopy (Fig. 1). The occluded virions were similar in dimensions and structure to the non-occluded virions.

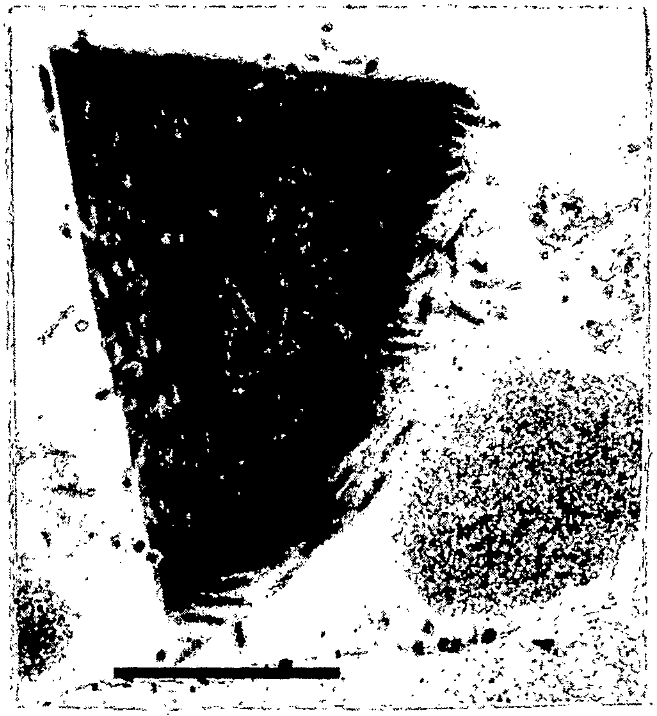

Fig. 4 Higher magnification (EM) of occlusion body from Fig. 3. Note virions occluded randomly within body. This body has a two-dimensional triangular form of crystalloid inclusion body observed with light microscopy in nuclei of hepatopancreatic cells; compare with Fig. 1 (bar=1 μm).

Evidence suggesting early stages of virion formation was found in altered nuclei (20% of cell profiles from exposed shrimp) that contained few or no completely formed virions. U-shaped membranous arrays occurred in these hypertrophied nuclei (Fig. 2*a*). These arrays and associated immature virions were similar to certain stages in early virogenesis of *Rhabdionvirus oryctes* in the rhinoceros beetle[7], and of the virus reported from the whirligig beetle[6].

Ultrastructural cytopathic alterations were associated with the presence of virions. Nuclei that contained virions in large numbers were often 1.5–2 times greater (hypertrophied) in profile area than normal nuclei (Fig. 3). Their cytoplasms, however, usually exhibited no parallel difference in profile area. Heavily affected nuclei had a distinct loss of heterochromatin (Fig. 2*a* and *b*), and some affected nuclei had no heterochromatin. Nucleolar degeneration was evident in nuclei that contained many virions (Fig. 2*b*). The most remarkable change associated with the presence of large numbers of virions was a proliferation of nuclear membranes (Fig. 2*a* and *b*), and their eruption into the cytoplasm to form a multimembranous labyrinth (Fig. 2*b*). Cells whose nuclei contained many virions possessed cytoplasms filled with ribosomes, but without normal numbers of mitochondria or endoplasmic reticulum vesicles (Fig. 2*a* and *b*). Most of these changes have been observed in cells of insects that were infected by *Baculovirus*. At present it is not known if exposure of infected shrimp to PCB enhances the cytopathic effects of the virus.

The following findings suggest a close relationship of the shrimp virus to the *Baculovirus* group[10] of invertebrate viruses. The virions were found in nuclei of hepatopancreatic cells of an arthropod (these cells are analogous in many aspects to fat body and midgut cells of insects). They are rod shaped (bacilliform), enclosed by one to two envelopes or capsids, found both free in nuclei and occluded in crystalline bodies within nuclei[10], and were 288 nm long by 75 nm in diameter, thus falling within the size range of *Baculovirus*[9,10]. Stromata which seemed to be virogenic were present in affected nuclei, and cytopathic alterations of affected cells and nuclei were similar to those reported for *Baculovirus* infections in insects.

In summary, a rod-shaped, free and occluded virus exists in a marine shrimp, indicating that marine crustacea are potential hosts for viruses similar to certain viruses infecting insects and mites. So far, the virus has been found only in shrimp taken from near Cedar Key and experimentally exposed to the toxic chemical, Aroclor 1254 (PCB). The virus probably is a natural parasite, however, previously undetected, of estuarine and marine shrimp.

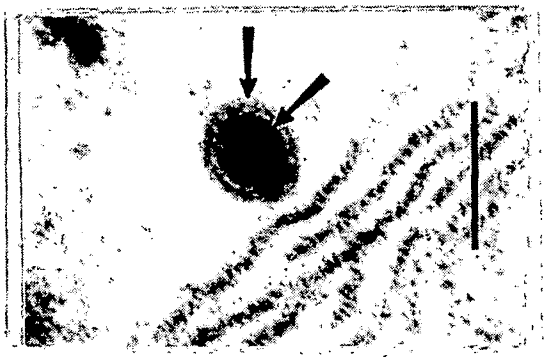

Fig. 5 Cross section of free virion in nucleus near abnormal, multimembranous (six membranes) nuclear envelope; note outer envelope and capsid of the nucleocapsid of virion (arrows) (bar=0.1 μm).

Studies of possible interactions of the PCB and virus in pink shrimp may provide valuable information needed to clarify the relationship between natural infectious diseases and pollutant chemicals in the aquatic environment.

I thank Dr D. R. Nimmo for collecting and exposing the shrimp, Dr Jean Adams for advice, Drs John Briggs, C. Vago and Max Summers for examining electron micrographs and for suggestions. Mrs Leslie Cupp and Mr Steve Foss gave technical assistance.

Inhibitory Effects of Individual Components of the Sex Pheromone of a Tortricid Moth on the Sexual Stimulation of Males

RECENTLY, *cis*-9 and *cis*-11-tetradecen-1-ol acetates, the principal components of the sex pheromone of the smaller tea tortrix, *Adoxophyes fasciata*, and the summerfruit tortrix, *A. orana*, were isolated from virgin females, identified and synthesised[1–3]. Individually, neither component was active even when presented in unusually large amounts. Furthermore, most male moths failed to respond when the two compounds were presented in sequence within a few seconds of each other. In contrast, a mixture of the two compounds at the 10^{-5} μg level elicited the characteristic sexual response from the male moths. Some studies on sex pheromone perception have revealed that geometrical isomers strongly inhibit the response of male moths to their sex pheromone[4–7]. These facts prompted us to examine the effects of individual compounds and their geometrical isomers on the sexual behaviour of the smaller tea tortrix. We found that the individual pheromone components, but not geometrical isomers, had an inhibitory effect on male stimulation by the sex pheromone.

After synthesis, *cis*-9 and *cis*-11-tetradecen-1-ol acetates, and their geometrical isomers, were purified by thin-layer chromatography on $AgNO_3$-impregnated silicic acid and by gas chromatography on 15%-PEGA on Chromosorb W AW. The bioassay procedure was based on that of Tamaki *et al.*[8], in which the mating dance of male moths was used as the criterion of response. The two compounds were assayed individually and in equimolar mixtures by applying them to pieces of filter paper and then exposing ten male moths of the smaller tea tortrix in 200-ml flasks. The quantities of each compound applied varied from 5×10^{-5} to 5×10^{-2} μg. A minimum of four replications was used for each test.

Results are summarised in Table 1. Mixtures of the two compounds evoked a potent response of the male moths ranging from 74% at the lowest concentration tested (5×10^{-5} μg of each compound) to 90% at the highest level tested (5×10^{-2} μg of each compound). When presented individually, however, neither compound elicited the mating dance. *cis*-11-tetradecen-1-ol acetate presented 1 min after males had been exposed to the *cis*-9-isomer also failed to evoke more than a 4% response. Surprisingly, the mixture of *cis*-9 and *cis*-11-isomers also evoked no response when presented 1 min after previous exposure to more than 5×10^{-4} μg of individual isomers. This mixture did elicit a potent response, however, from a group of male moths that had not been previously exposed to the individual compounds. In contrast, previous exposure to the geometrical isomers, *trans*-9 and *trans*-11-tetradecen-1-ol acetates, in concentrations equivalent to the pheromonal components, had no inhibitory effect on the sexual stimulation of males when exposed to the active pheromone.

Clearly the individual sex pheromonal components inhibit the subsequent stimulatory response of male moths of the smaller tea tortrix to the sex pheromone. The inhibitory effect of each pheromone component was apparent when there was an interval of only a few seconds between pre-exposure to one component and subsequent exposure to the mixture. The inhibitory effect was also confirmed by using virgin females. Suppression of mating was 90% and 60% in males pre-exposed for 1 min in 200-ml flasks to 10^{-2} μg of *cis*-9-isomer and *cis*-11-isomer, respectively. The inhibitory effect of individual components of the sex pheromone on sexual behaviour of males of the smaller tea tortrix seems to be involved in the isolation of the smaller tea tortrix from any sympatric species that uses either *cis*-9 or *cis*-11-tetradecen-1-ol acetate as the sex pheromone. Although the olfactory

† Criterion of male response is the 'mating dance'.

mechanisms of the moth are not yet understood, it seems that the male moths possess a complex mechanism that needs simultaneous receipt of the two components of the sex pheromone for release of subsequent sexual behaviour.

The present finding suggests a new approach for controlling the smaller tea tortrix by using only one component of the sex pheromone.

Genetically Based Behaviour Patterns in *Drosophila melanogaster*

Some time ago Bastock[1] demonstrated that yellow (*y*) mutant males of *Drosophila melanogaster* had reduced success in fertilising normal females. This tendency of females to reject *y* males provides a means by which variation in behaviour between populations might be easily studied.

The studies reported here involve four populations of *Drosophila*. A laboratory wild type (+), a *y* mutant strain, both obtained from Turtox, and two wild type strains (No. 6 and No. 32) collected locally. The last two were selected from a larger collection of eight local populations, preliminary studies of which indicated a considerable variation in the rejection of *y* males by females. The four populations were studied with respect to the extent to which females rejected *y* males. The study was extended in an attempt to select a strain of females which would show a preference for *y* males. We are motivated by a general interest in the examination of genetically based behavioural differences between populations, and the extent to which such differences may be manipulated by selection.

The experiments described are based on the following technique. A single adult virgin female, that had been kept for 2 or 3 d in a small tube with medium, was added, unetherised, to a vial containing medium and in which two males had been present for a similar period of time. Except where otherwise noted, one male was obtained from the same population as the female, and the other from the *y* mutant population.

Table 1 Choice of Males by Females

Female	Males	Success to *y* male	Success to other male	Unknown
No. 6	6, *y*	9	48	8
No. 32	32, *y*	6	137	21
+	+, *y*	3	43	19
y	+, *y*	164	208	18

Comparisons between the populations are shown in Table 1. The experiments were carried out at 25° C, and matings were observed for a period of 2 h from the time of the introduction of the female. Any matings not completed by that time are classed as 'unknown'. Significant differences with respect to the rejection of the *y* males exist between the two local populations, collected from areas approximately three miles apart ($P<0.01$). The *y* females show the highest acceptance of *y* males. Clearly, however, no preference for *y* males exists in any of the populations.

Selection for enhanced acceptance of the *y* males was carried out as follows. Virgin adult female progeny were taken from one or more successful matings to a *y* male in the above experiments, and presented to a pair of males similar to those in the initial experiments. Thus both males are from the initial populations, while the female is from a cross between members of these populations. The next generation of females is again selected from successful crosses to *y*, and these females are again presented to males from the initial populations. Thus a No. 6 female mating with a *y* male gave rise to 6–1 females, and 6–1 females mating with *y* males gave rise to 6–2 females. Either one or two families were used for each generation; thus in each of the first two selected generations one family was used, while in generation 3, for strain 6, two families were used (6–3–1 and 6–3–2). 6–3–1 is derived from one of the two successes to *y* in the previous generation, and 6–3–2 from the other. Selection was only for females; the males were always obtained from the unselected parental populations. Results of the selection experiments for populations No. 6 and No. 32 are shown in Table 2.

It can be seen that no significant differences exist between the data for the first four generations for population No. 6; in fact the data do not differ significantly from that presented for No. 6 in Table 1. A marked change can be seen in the fifth generation where a preference for the *y* male can be seen; this preference is again seen in the sixth and seventh generations. The rareness of successful matings to *y* by No. 32 females accounts for the fewer generations with respect to this population; the data suggest that this population may be less amenable to selection for successful matings with *y* males.

Table 2 Selection for Enhanced Preference for *y* Males

Female and generation	Males	Success to *y* male	Success to other male	Unknown
6–1	6, *y*	4	7	0
6–2	6, *y*	2	35	5
6–3-1	6, *y*	8	25	5
6–3–2	6, *y*	5	15	3
6–4	6, *y*	5	40	4
6–5–1	6, *y*	25	11	11
6–5–2	6, *y*	34	8	9
6–6–1	6, *y*	12	7	7
6–6–2	6, *y*	14	8	2
6–7–1	6, *y*	13	7	3
6–7–2	6, *y*	16	7	5
32–1	32, *y*	2	40	10
32–3	32, *y*	3	21	6
32–3	32, *y*	11	15	4
32–4	32, *y*	12	31	1
32–5–1	32, *y*	6	10	16
32–5–2	32, *y*	8	10	10

It should be realised that females of generations 6–5, 6–6 and 6–7 must contain large amounts of the *y* strain genotype, indeed parts of the *y* strain genotype must be present in all the selected females. Additional experiments in which the original pure *y* females are provided with a choice of No. 6 or *y* males show that the genotype of the pure *y* strain cannot alone account for the results in generations 6–5, 6–6 and 6–7 presented in Table 2. Thus, when the original pure *y* females were provided with a choice of No. 6 males or *y* males, sixty-one chose No. 6 males, twenty-seven chose *y* males and ten were unknown. It can be seen, then, that when pure *y* females are given the choice of No. 6 males or *y* males, the rejection of *y* males is even greater than when their choice is between the laboratory wild type and *y* males (see Table 1). The genetic basis of the preference for *y* males shown by selected females (Table 2) derived from the families 6–5–1,2, 6–6–1,2, and 6–7–1,2 must involve genes from both the original No. 6 strain and from the pure *y* strain, a further understanding of which must await a more detailed genetic analysis.

The results presented here are interesting in a number of respects. At present the simplest way of distinguishing between the two populations, No. 6 and No. 32, is by their behavioural differences described above. Although the *y* mutant is known to be associated with a single gene mutation, the genetic basis of the rejection of *y* males by females is unknown. It is possibly misleading to regard *y* males as offering a low level of stimulus, without carefully defining the mating system. We believe that use can be made of the genetic differences, present in female populations, of preference and rejection for *y* males, shown in the above experiments, in a closer examination of the female responses to male courtship signals.

Microcapsules as Artificial Food Particles for Aquatic Filter Feeders

IT has long been the aim of the aquaculture industry to replace natural foods with artificial diets which can be manufactured and stored, and there is an obvious need for the development of a successful artificial diet for aquatic filter feeders. Furthermore, if such diets are defined, they can be used to elucidate the exact nutritional requirements of the animals under culture. Provasoli and his co-workers[1,2] have shown that *Artemia* can be reared in a sterile medium, but that a particulate phase is necessary to promote growth beyond the third stage metanauplii.

Artificial food particles are known to be acceptable to a wide range of filter feeders[3,4]. In our experience, food supplied in a particulate form as egg slurry or minced fish[5], or adsorbed on to the surface of particles, invariably leads to bacterial contamination with subsequent deleterious effects. An alternative approach is to use encapsulated diets in which the components are retained within an artificial membrane. The use of microencapsulation techniques in aquaculture has been advocated recently by Meyers and co-workers[6,7] but, until now, no experimental results have been made available. The type of microcapsule that is required depends on the mode of feeding. In the case of molluscan larvae and adult bivalves, which ingest their food whole, the capsule wall should be impermeable and stable in seawater, but readily broken down by a change in *p*H or by the action of digestive enzymes. As far as we are aware, capsules of this type have not been described in the literature. Alternatively, for those larvae or adults which masticate their food, the capsule wall need only be broken mechanically to allow the contents to be ingested.

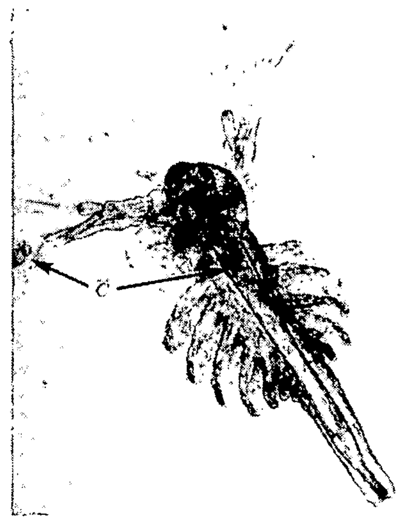

Fig. 1 Microcapsules fed to *Artemia*.

Microcapsules of this second type, with cross linked nylon-protein walls, can be prepared in the laboratory using a modification of the method described by Chang *et al.*[8]. 4,4′-Diamino-2,2′-biphenyldisulphonic acid (6 mmol l^{-1}) is added to give the membrane a resultant negative charge which reduces aggregation of the capsules. The concentration is twice that recommended by Chang *et al.*, to allow for the ionic effects of seawater and to increase the brittleness of the membrane. It was also necessary to double the concentration of sebacoyl chloride (0.036 M) to produce satisfactory capsules in the right size range (20 to 80 μm diameter). The capsule walls are easily ruptured by crustacean mouthparts and a wide range of water-soluble materials and particulate matter can be encapsulated to give almost neutrally buoyant capsules in a size range 5 to 200 μm. The main disadvantage of this type of capsule is that the nylon-protein wall is permeable to small molecules but the capsules can be used to produce defined macromolecular food particles containing starch and protein.

Various Crustacea have been observed feeding in suspensions of microcapsules and it has been shown that all the animals studied, *Macrobrachium* zoea, *Carcinus* zoea, late stage *Balanus* and *Elminius* nauplii, adult *Temora*, and *Artemia*, can rupture the capsule walls and ingest the contents, sometimes together with the crushed outer membrane. Figure 2 shows that, after 4 d, the percentage survival of *Artemia* fed on microcapsules containing 5% starch and 10% haemoglobin exceeded that of the starved controls. After 10 d, 25% of the fed *Artemia* had survived whereas all the starved animals had died. To obtain a mean value for 'growth' within the population of *Artemia*, we have used the growth index of Provasoli *et al.*[2]. This is an arbitrary value related to size and the moult stage reached. The base line is provided by the starved controls. Figure 2 shows that *Artemia* will not progress beyond the third metanauplius stage (growth index 4) without food[1]. Those animals fed on microcapsules, and which survived, reached a growth index of 11 after 34 d with an average development to the juvenile stage although a few individuals reached the adult stage. Clearly, growth and survival was less than that achieved with *Isochrysis* but the encapsulated diet was incomplete and the starch: protein ratio was not optimal for growth of *Artemia*[2].

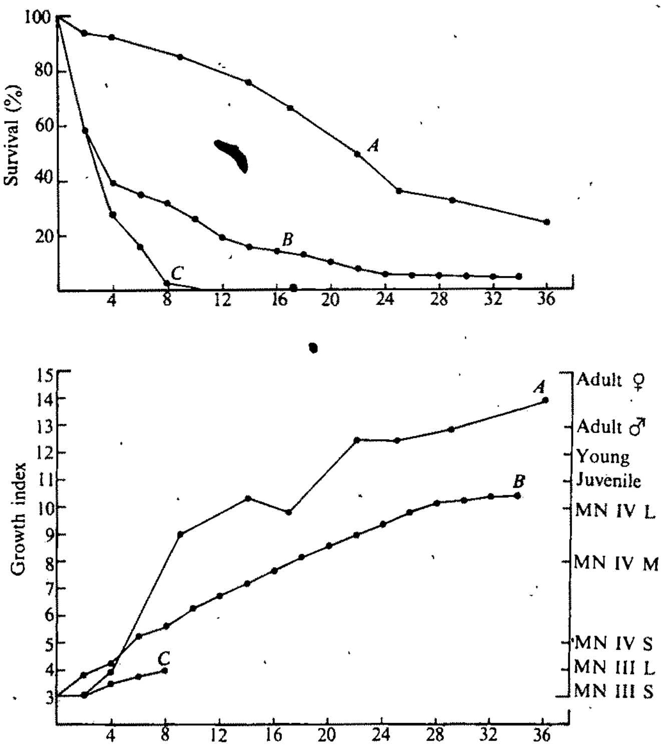

Fig. 2 Survival and growth of *Artemia*. Growth experiments were carried out at room temperature in beakers containing 600 ml of aerated seawater and 120 to 180 *Artemia*. The results are given as the means of two or three replicated experiments, *B* and *C*, and of a single experiment, *A*, with *Isochrysis galbana*. Microcapsules contained 5% soluble starch and 10% haemoglobin. The concentration of food particles was kept in excess of the daily intake for *Artemia* and the seawater and food changed each time the animals were counted. Penicillin G and streptomycin sulphate were added to the cultures at concentrations of 30 mg l^{-1} and 50 mg l^{-1} respectively. *A*, *Isochrysis*; *B*, microcapsules; *C*, starved controls.

A further experiment was carried out to show that U-^{14}C-labelled starch, contained in microcapsules, is assimilated by *Artemia* and the glucose carbon is incorporated into amino acid metabolism. Previous work with Crustacea[9] has shown that carbon from U-^{14}C-glucose is readily incorporated into alanine, glutamic acid, aspartic acid and glycine. Approximately 200 late metanauplius to young adult *Artemia* were fed with microcapsules containing 5% starch (1 μCi mg^{-1}) and 10% haemoglobin for 48 h at 18° C in a litre of seawater. At the end of the feeding period the *Artemia* were removed and washed with isotonic ammonium formate solution, freeze dried and powdered in a micro ball mill. A sample of the dried *Artemia* was extracted with 5% trichloroacetic acid (TCA) and the insoluble protein residue oxidised with performic acid as described by Hirs[10], and hydrolysed with 6 N HCl. The constituent amino acids were separated by one-dimensional thin-layer ion-exchange chromatography[11] and made visible by spraying with a ninhydrin reagent. Radioactivity was determined by scanning the TLC plate using a Berthold Thin-layer Scanner II with a slit width of 1 × 16 mm.

Figure 3 shows that glucose carbon from encapsulated U-^{14}C starch is assimilated by *Artemia* and incorporated into the non-essential amino acids alanine, glutamic acid, aspartic acid and glycine resulting in ^{14}C-labelled protein. No attempt was made to calculate the radiochemical recovery in the protein fraction except to note that the activity was low with a maximum count rate only twice the background count. A further sample of *Artemia* was extracted with chloroform-methanol and the neutral lipid classes separated by TLC on silica gel. Traces of ^{14}C-label were detected in the fatty acid component.

It has been our intention to show that microencapsulation represents a feasible approach towards the development of artificial diets for filter feeders. Animals with very different food preferences, ranging from *Artemia* cultured on phytoplankton, to *Macrobrachium* zoea which feed on *Artemia* itself, were observed to accept and ingest the contents of microcapsules provided these were supplied in the correct size range, 20 to 250 μm. Although the ideal capsule should have an impermeable membrane which could either be ruptured mechanically or broken down by digestive activity, much can still be accomplished with the present capsules despite their permeability. Capsules containing starch and protein could be used as artificial food particles, together with natural food organisms, to provide essential nutrients such as vitamins. Lipids might also be adsorbed on to starch particles and incorporated into the capsules, which could then be used to determine the optimum starch: protein: lipid ratios for filter feeders. Metabolic studies in which ^{14}C-labelled starch (or protein) is incorporated into capsules are already possible. Labelled fatty acids could be adsorbed on to starch particles as described by Morris *et al.*[12] and encapsulated for filter feeders. In addition, other metabolites or foreign compounds could be fed in an encapsulated form either adsorbed or attached covalently to a suitable high molecular weight carrier molecule.

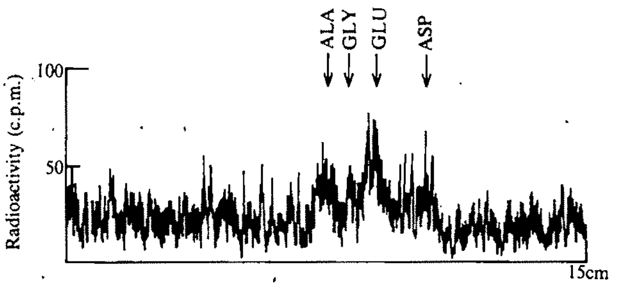

Fig. 3 Separation of constituent amino acids from protein hydrolysate of *Artemia*. Precoated Ionex-25 SA, Na^+ form TLC plate (Macherey, Nagel and Co.) without pre-equilibration. Elution buffer, *p*H 3.3, sodium citrate, 0.4 N Na^+, 0.4 M citrate at 50° C. Approximately half the total protein hydrolysate from 2 mg freeze-dried *Artemia* was applied to the plate as a 1 cm band and eluted to a distance of 15 cm. Individual amino acids were identified by comparison with a mixture of known standards.

Part of this work was supported by a grant from the Natural Environment Research Council.

Degradation of *p,p'*-DDT in Reducing Environments

p,p'-DDD (*p,p'*-TDE; 1,1-dichloro-2,2-bis (*p*-chlorophenyl) ethane) is an extremely persistent environmental contaminant[1]; it is a well known insecticide but is also derived from *p,p'*-DDT (1,1,1-trichloro-2,2-bis (*p*-chlorophenyl) ethane) in the environment by a process of reductive dechlorination. The conversion of DDT to DDD has been observed in a wide variety of biological systems, both living and dead[2]. The mechanism by which this degradation of a highly chlorinated molecule takes place in the environment is of considerable interest but has not been clearly established[3,4].

We have recently re-examined the environmental degradation of DDT and have measured DDD/DDT ratios after exposing DDT to a variety of conditions: sterile and non-sterile; oxidising and reducing; and appropriate combinations. The systems examined were: (1) sewage sludge, (2) baker's yeast, (3) iron salts and iron porphyrins, (4) bacterial cultures and (5) annelid worms. The results from this set of conditions, which ranged over complex biological situations, pure cultures and chemical systems, have led us to the conclusion that the conversion of DDT to DDD in the environment is mediated by reduced iron porphyrins and is not an essential part of cell metabolism.

Secondary sewage sludge converts DDT to DDD under anaerobic conditions[5-8], with a half-life of as little at 3 h, but DDD is itself stable. The data in Table 1 show that not only is this ability not destroyed by sterilisation with γ-radiation (Experiments 1 and 5) but that even after inactivation by aeration (Experiment 6) or by autoclaving[5] (Experiment 3), activity can be restored instantly if the *Eh* is sufficiently lowered by addition of sodium dithionite (Experiments 4 and 7), a reducing agent widely used in biochemical studies[9]. This suggests to us that direct microbial metabolism does not account for the reductive dechlorination of DDT in untreated sewage sludge.

Table 1 Degradation of *p,p'*-DDT in Anaerobic Sewage Sludge

Exp. No.	Sterilisation	Reduction or oxidation	*Eh* (mV)	DDD/ DDT	% ^{14}C extracted
1	—	—	−285	0.8	71
2	—	Dithionite	−660	2.0	63
3	Autoclaved	—	−210	0.1	84
4	Autoclaved	Dithionite	−640	2.3	76
5	5 Mrad γ	—	−220	1.0	56
6	—	Aerated	+50	0.1	71
7	—	Aerated, then dithionite	−645	1.7	57

Aliquots (10 ml) of anaerobic sewage sludge were sterilised (15 pounds per square inch, 15 min or ^{60}Co source at 0.45 Mrad h^{-1}) and reduced (50 mg sodium dithionite in 0.5 ml water) or oxidised (rapid aeration for 90 min at 20° C) as indicated. ^{14}C-*p,p'*-DDT (107 μg, 0.45 μCi) in ethanol (0.1 ml) was added to each sample and the mixtures incubated (37° C, 90 min). The sludge was obtained from the anaerobic digestor of the Bristol Corporation Sewage Treatment Works, and was concentrated by decantation to 5% dry weight solids. ^{14}C-*p,p'*-DDT (98% pure) was obtained from the Radiochemical Centre, Amersham, and unlabelled *p,p'*-DDT from Aldrich (99% pure). *Eh* measurements were made with a platinum spear electrode, a calomel reference electrode and a Philip Harris *p*H and Redox meter: readings were taken 1 min after the electrodes were inserted into the sample and the platinum spear was flame-cleaned between each determination. The samples were extracted (hexane : isopropanol 1 : 1, 3 × 10 ml), the combined hexane layers were analysed by GLC as previously described[6,8] and by scintillation counting. DDD/DDT ratios are calculated directly from peak heights. Aqueous dithionite alone yielded only a small amount of DDD (see Table 3). Results shown are the mean of duplicate determinations. The DDT and DDD together account for 30–60% of the extracted ^{14}C. More polar products, similar in chromatographic behaviour to those noted by Miskus *et al.*[13], account for the remainder of the label in these and in the relevant experiments quoted in Tables 2 and 3.

A readily available microbial system is baker's yeast in which Kallman and Andrews[10] have reported substantial conversion of DDT to DDD over periods of several days. In our experiments, however (Table 2), no significant reaction took place in fresh yeast suspensions in 1.5 h at 37° C unless the *Eh* was lowered by addition of sodium dithionite. Previous autoclaving brought a marked enhancement of this effect, suggesting that autoclaving released a chemical factor which at the appropriate *Eh* was an effective reducing agent for DDT.

Various putative reductants for the DDT to DDD conversion have been put forward. For example, Glass[11] claimed that a ferrosoferric-ferrous couple was effective at high *p*H, but we achieved only a very slow reaction. Increasing the ferrous ion concentration in sewage sludge did not significantly increase the ability of the sludge to degrade DDT to DDD, nor did it restore this ability to autoclaved sludge. Addition of ethanol to increase the solubility of DDT in the presence of ferrous ions also failed to increase the extent of reaction. Castro[12] reported the rapid oxidation of a reduced iron porphyrin by DDT in isopropanol : acetic acid (1 : 1) saturated with KCl under nitrogen. Later, Miskus *et al.*[13] suggested that reduced porphyrins might be the factor responsible for conversion in biological systems. This attractive suggestion has been reiterated[5,14] and cytochromes

Table 2 Degradation of *p,p'*-DDT Yeast Cell Suspensions

Sterilisation	Reduction	*Eh* (mV)	DDD/ DDT	% ^{14}C extracted
—	—	+165	0.1	91
—	Dithionite	−510	0.4	91
Autoclaved	—	+50	0.1	97
Autoclaved	Dithionite	−600	1.3	91

Aliquots (10 ml) of an aqueous 10% w/v suspension of commercial yeast (Distillers, Yeast and Food Division) were used. The materials and procedure were otherwise the same as described under Table 1.

and other protein-bound haem compounds have since been shown to degrade DDT slowly under reducing conditions[15]. Using haematin dissolved in dilute sodium hydroxide ($pH > 11$) Miskus *et al.*[13] obtained 10% conversion of DDT to DDD in 4 h with sodium dithionite as a reducing agent. Solubility is a problem in conducting experiments with Fe(II) porphyrins in the *p*H range normally associated with biological systems. Haematin (the Fe(III) porphyrin corresponding to the Fe(II) porphyrin, protohaem) is soluble in aqueous 0.1 N Na_2CO_3 but precipitated when it was reduced to protohaem by the addition of sodium dithionite. The addition of a detergent or ethanol prevented this precipitation and the results we thus obtained with protohaem and DDT are shown in Table 3. The conversion of DDT to DDD can therefore be accomplished rapidly and in a catalytic manner by an Fe(II) porphyrin at a *p*H frequently associated with biological systems (Table 3; Experiments 1–3). Rapid degradation of DDT was also obtained when ferrous sulphate was substituted for sodium dithionite (Experiment 4), but no significant degradation was observed with ferrous sulphate under conditions similar except for the absence of haematin. The addition of haematin and detergent to anaerobic sewage sludge greatly increased the DDT to DDD conversion (Experiments 7–10).

Table 3 Reaction of *p,p′*-DDT with Reduced Haematin

Exp. No.	Haematin (mg)	Tween 80 (mg)	Ethanol (ml)	Reducing agent	DDD/DDT	% ^{14}C extracted
1	0.6	—	—	Dithionite	0.25	54
2	0.6	25	—	Dithionite	0.83	42
3	0.6	—	1.0	Dithionite	2.7	84
4	0.6	25	—	Ferrous sulphate	1.9	28
5	—	25	—	Dithionite	0.09	46
6	—	—	1.0	Dithionite	0.06	95
7	—	—	—	Sludge	0.21	96
8	0.3	—	—	Sludge	0.36	85
9	—	200	—	Sludge	0.85	80
10	0.3	200	—	Sludge	3.5	81

DDT (3.55 mg, 0.1 μCi in Experiments 1–6; 1.78 mg, 0.05 μCi in Experiments 7–10) in ethanol (0.2 ml and 0.1 ml respectively) was added to each mixture of haematin (Koch-Light Laboratories), Tween 80 (Hopkin and Williams), ethanol, 0.5 ml 0.1 N aqueous Na_2CO_3 solution, and chemical reductant (25 mg) or sludge (10 ml). The source of the DDT and the incubation and analytical procedures were as described for Table 1, except that in Experiments 1–6 products were extracted into 10 ml ether by very vigorous agitation. The DDT : haematin molar ratio was 10 : 1.

The foregoing chemical experiments demonstrated that DDT to DDD conversion was effected in any situation in which DDT and reduced iron porphyrins were brought together in solution.

Reports have appeared and continue to appear[4,10,16–20] reporting organisms which either do, or do not, readily metabolise DDT but they do not, mostly, purport to show the use of DDT as a sole carbon source. Our next experiment simulated the natural exposure of DDT to porphyrins, or porphyrin-like compounds, contained in microorganisms, at various oxidation/reduction potentials.

Bacteria derived from anaerobic estuarine sediments were grown in a chemostat on a medium containing about 10 p.p.m. DDT. Dilution rates down to 0.25 h^{-1} were used, gassed either with air to maintain aerobiosis or with nitrogen. We failed to observe any degradation of DDT under these conditions of continuous growth. But when the chemostat was turned off, DDT conversion was soon observed in the culuture vessel and also occurred in the effluent reservoir where there was considerable autolysis.

In another experiment, pure cultures of twelve species of bacteria from ten genera were grown aerobically on nutrient agar overnight and collected, and aqueous suspensions containing about 10^9 viable cells ml^{-1} were incubated with 10 p.p.m. DDT, with and without sodium dithionite, at 37° C for 1.5 h. Conversion of DDT was significant only in cell suspensions containing dithionite and was enhanced by using cell suspensions which had been previously heated at 100° C for 10 min.

In a laboratory experiment[21] individuals of *Arenicola marina* (lugworms) living in well-aerated artificial burrows containing 2,000 p.p.m. of DDT were unable to degrade ingested DDT. But 48 h after death, when lysis and decay were well established, about 70% of the incorporated DDT was found to be converted to DDD and other products, confirming similar reports[1–3,14] of degradation by dead animal tissues in anaerobic conditions or where no precautions had been taken against bacterial decay.

We believe that the foregoing rationalisation and extension of existing data bearing on the reductive dechlorination of the normally highly persistent DDT molecule has considerable environmental significance. Most living material contains iron porphyrins bound with protein in complex molecules such as haemoglobin, cytochromes and catalases. Decay should release iron porphyrins[22] which, under the reducing conditions pertaining in the anaerobic environments characteristic of dead and decaying matter, would catalyse rapid conversion of any available DDT to DDD and other products. In terms of the breakdown of the total world mass of DDT this pseudo-biological mechanism could appreciably affect the environmental half-life, since it would come into operation whenever the DDT encountered the appropriate situation in passing through the food web. Anaerobic microenvironments are ubiquitous and include the sulphide biome of reducing sediments[23], the decaying cell contents of dead organisms and the lower portions of the alimentary tract of animals. The operation of such a process should result in high DDD/DDT ratios in the tissues of animals scavenging on dead and decomposing organisms.

Work is in progress to identify the other products formed in the reaction of DDT with reduced iron porphyrins and to seek evidence for the occurrence of this reaction in various environments.

We thank the Natural Environment Research Council for a research grant and Miss Jennifer J. Wood for contributing the data from experiments with lugworms.

Freezing resistance in winter flounder *Pseudopleuronectes americanus*

THE blood serum freezing points of most marine teleosts are within the range of −0.5 to −0.8° C[1]. As large regions of the oceans have temperatures as much as 1° C below this range[2], many marine fish must either increase the osmotic concentrations of their blood or exist in a supercooled state. The latter is unstable and in the presence of ice, supercooled fish will freeze and die.

The winter flounder, *Pseudopleuronectes americanus*, inhabits the coastal waters of eastern North America from Virginia to Labrador[3]. In the northern part of their range they occur during the winter in large numbers in ice-covered shallow bays[4]. Using a freezing point osmometer (Fiske) Pearcy[5] found that the blood serum of winter flounder from the Mystic River Estuary, Connecticut froze at −0.63° C during summer and at −1.15° C in winter. NaCl accounted for 83% of the freezing point depression in summer, but only 57% in winter. The solutes responsible for the remainder of the depression in winter fish were not identified. Umminger[6] investigated freezing resistance in winter flounder taken from the same area. Using data obtained with a vapour pressure osmometer he concluded that the serum freezing points of winter fish were not unusually low (−0.71° C).

TABLE 1 Freezing point, melting point and inorganic constituents of whole and dialysed serum from *Pseudopleuronectes americanus*.

Specimen and environmental parameter	Freezing point (° C)	Melting point (° C)	Melting point − freezing point (° C)	Sodium (mM l⁻¹)	Chloride (mM l⁻¹)	% △ due to NaCl
Winter flounder serum March; water − 1.2° C (12)	−1.37 ± 0.31	−0.75 ± 0.03	0.62 ± 0.35	250 ± 12	178 ± 6	58.1
Winter flounder serum August; water + 17° C (8)	−0.69 ± 0.07	−0.67 ± 0.07	0.02 ± 0.001	194 ± 6	147 ± 14	94.0
Winter flounder March; water − 1.2° C						
Dialysed serum	−0.65	−0.01	0.64	—	0.0	
Dialysate	−0.72	−0.70	0.02	—	172	

During the winters of 1972 and 1973 we investigated the freezing resistance of winter flounder collected by trawl at depths of 3 to 10 m in Head Harbor of St Margaret's Bay, Nova Scotia. Specimens were collected in March, a few days after the ice had begun to break up, when the water temperature was −1.2° C. The lower incipient lethal temperature (freezing temperature) determined by recording the lowest temperature at which the flounder could survive in the presence of ice was −1.4 ± 0.1° C.

In the serum of the Antarctic fish, *Trematomous borchgrevinki*, there is a group of organic 'antifreeze' compounds (glycoproteins) responsible for the serum's unusually low freezing point[7]. These glycoproteins lower the freezing point of water without affecting the melting point by coating the surface of ice crystals, thereby removing them as possible nucleation sites[8,9].

To determine whether freezing resistance in the winter flounder is based on a similar mechanism, the freezing-melting behaviour of their serum was studied.

The freezing and melting points of serum samples were determined by placing the serum in small capillary tubes which were sealed at one end and plugged with mineral oil at the other. A small seed crystal was formed in the sample by spray freezing and the sample immersed in a refrigerated viewing chamber. The temperature of the chamber was controlled to within ±0.01° C and the seed crystal (0.25 mm diameter) viewed through a microscope. The temperature of the bath was raised or lowered 0.02° C per 5 min. The temperature at which the seed crystal disappeared was taken as the melting point and that at which the crystal grew as the freezing point. For an NaCl solution, the temperatures of melting and freezing are within 0.02° C of each other. For the serum of winter flounder collected in March, however, the freezing and melting points are widely separated (Table 1). This difference has been termed thermal hysteresis. Serum sodium and chloride ion concentrations accounted for 58% of the serum freezing point depression (−1.37° C) of March flounder and 94% for serum from fish collected in August when the water temperature was 17° C (serum freezing point = −0.69° C).

Dialysis showed that the major portion of the freezing point depression not due to NaCl in March fish was associated with the colloidal fraction of the serum. After exhaustive dialysis (tubing of molecular weight cutoff 3,500 daltons) against distilled water both the dialysed serum and the dialysate were returned to the original volume. Table 1 shows that the solutes responsible for the thermal hysteresis were unable to pass through the dialysis tubing and must therefore have molecular weights greater than 3,500 daltons.

These antifreeze compounds were stable at a temperature of 100° C and soluble in 10% trichloroacetic acid (TCA). Therefore, a crude preparation of the antifreeze was made by dialysing the serum and boiling it for 10 min followed by centrifugation at 15,000*g* for 20 min. The supernatant was diluted (1:10) with TCA and again centrifuged. After the TCA was removed from the supernatant by dialysis, lyophilisation resulted in a fluffy white residue. The freezing and melting points of aqueous solutions of this antifreeze preparation were determined at several concentrations (Fig. 1). The difference in freezing and melting points varied with concentration.

The discovery of thermal hysteresis in winter flounder serum shows that the lowering of the freezing point of water by the antifreeze is not a colligative effect. In view of this, the freezing points reported by Umminger[6], which were derived from vapour pressure measurements, would not be expected to agree with those reported by Pearcy[5] as the vapour pressure of solutions is a manifestation of the number of dissolved particles. The serum freezing points (−0.71° C) observed by Umminger do, in fact, agree with the melting points we have obtained (Table 1). Freezing points measured with a freezing point osmometer are in reasonable agreement with those determined with the capillary technique. It is clear that in studies of freezing resistance, careful consideration should be given to choosing a method for determination of freezing points. Is seems that visual examination of crystal growth under a carefully controlled temperature regime is the best method and is biologically the most meaningful because it agrees with the organismal freezing point.

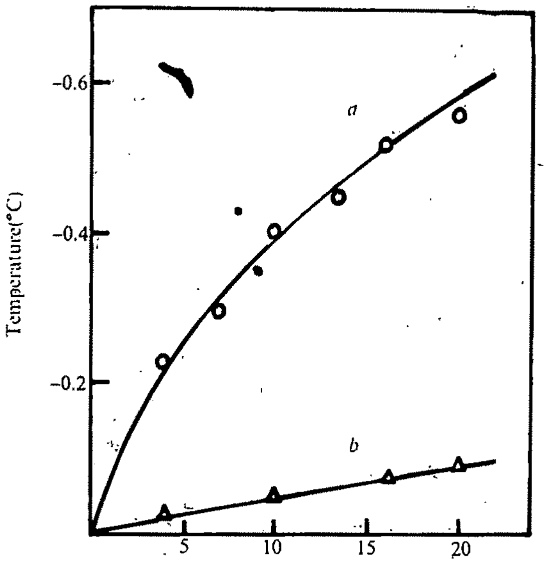

FIG. 1 Comparison of the freezing and melting points of aqueous solutions of antifreeze isolated from the blood serum of *Pseudopleuronectes americanus*. o, Temperatures of ice crystal growth in the presence of a seed crystal (freezing point); △, melting points of the seed crystal.

The freezing behaviour of the serum and partially purified antifreeze solutions was also studied by the use of freezing curves. The freezing points obtained with this technique agree with those obtained from the capillary method (Fig. 2 and Table 1). The shape of the freezing curve of the serum of the Canadian plaice, *Hippoglossoides plattessoides*, which does not produce an organic antifreeze, resembles that of NaCl because the principal solute responsible for the depression of the freezing point is NaCl. The shape of the curve of NaCl and the plaice serum results from the fact that as freezing proceeds pure water freezes out leaving behind a more concentrated salt solution with a lower freezing point. Thus, during freezing the temperature of the sample remains slightly warmer than the bath temperature until all the solvent freezes—at which time the sample temperature rapidly approaches that of the bath. The shape of the freezing curve of the serum of the flounder differs from that of the plaice by the presence of a slight flat region near the freezing point. The flatness is more pronounced in the freezing curve of a solution of flounder antifreeze and much more so in a solution of the glycoprotein antifreeze from the Antarctic fish. The long plateau region of the latter results from incorporation of the glycoprotein into the solid phase during freezing. The glycoproteins are equally partitioned between the liquid and solid phases which indicates they depress the freezing point of water by coating the surface of seed ice crystals, thereby preventing water molecules from joining the ice lattice[7–9]. Although no measurements have been made to show that the flounder antifreeze is equally partitioned between the liquid and solid phases during freezing, the flatness of its freezing curve strongly suggests that this is the case.

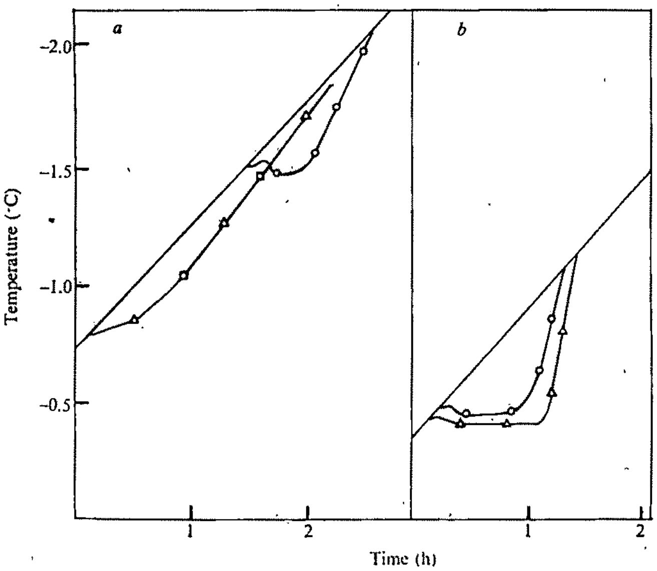

FIG. 2 *a*, Freezing curves of an aqueous 220 mM NaCl solution (△); of the blood serum of the Canadian plaice, *H. Plattessoides* (□); and winter flounder, *P. americanus* (o). *b*; Freezing curve of a solution of antifreeze (10 mg ml⁻¹) isolated from the serum of *P. americanus* (o); and of a solution of antifreeze (10 mg ml⁻¹) isolated from the blood serum of the antarctic fish *Trematomus borchgrevinki* (△). The freezing point obtained from a freezing curve is the temperature where the sample temperature deviates from the bath temperature—indicating a warming of the sample resulting from the latent heat of fusion.

The thermal hysteresis and the freezing curve data lead to the inference that the mechanism of action of the flounder antifreeze is similar to that of the glycoproteins in Antarctic fish. Acrylamide gel electrophoresis and amino acid analysis indicate that the antifreezes of the two fishes differ markedly in composition. Therefore, it seems that distantly related families of cold water fishes have adapted to freezing conditions by evolving different large molecular weight compounds which, however, possess similar antifreeze activity.

book reviews

Loving only the dead

Ten Years after Ivan Denisovich. By Zhores A. Medvedev. Translated from the Russian by Hilary Sternberg. Pp. xiv+202. (Macmillan: London and Basingstoke, November 1973.) £3.95.

THIS severely factual book, by a distinguished Soviet biologist temporarily working in England, encompasses three themes: the official persecution of Alexander Isayevich Solzhenitsyn; the elevation of the Big Lie to an instrument of policy; the ability of a profound creative writer who is also a fearless patriot to console the wounded spirit of his fellow citizens, oppressed not only by arbitrary cruelty but also by Universal Silence. For the reader in the West, Solzhenitsyn's novels are documentary accounts of reality distilled through the writer's imagination, and thereby an aesthetic experience: for the Soviet reader, they are the healing voice of truth, of great evil admitted, faced and endured.

Medvedev is a 'dissident' who has deserved well of his fellow Soviet citizens by disseminating, in *samizdat*, his detailed account of the official suppression of scientific genetics in the Soviet Union at the behest of the vicious charlatan, Lysenko. Solzhenitsyn wrote to Medvedev to encourage him when he was attacked for his factual writings about Lysenko, and their friendship stemmed from this act of support. The book under review makes it very clear how vital such acts of support by compatriots are to a Soviet citizen who is at odds with the authorities, and his recognition raises difficult questions for us in the West, who must decide whether our words of support are a help or a peril.

In his new book, Medvedev describes the circumstances of the publication in 1962 of *One Day in the Life of Ivan Denisovich* (on the express authority of Khrushchev who was then still concerned with surreptitiously blackening Stalin's memory); the first signs of official disapproval, when Solzhenitsyn was passed over for the Lenin Prize and had the manuscript of *The First Circle* and other papers confiscated; the prolonged but frustrated attempts by the remarkable literary editor, Tvardovsky, to publish *Cancer Ward* in his journal *Novy Mir*; the attempt to turn Solzhenitsyn into a non-person at the Fourth Writers' Congress; his expulsion from the Writers' Union and that of Tvardovsky from his editorship; the prolonged official chicaneries in connection with Solzhenitsyn's Nobel Prize, which in the event was never presented in person; and, running like a refrain through the whole book, the many attempts by officialdom to blacken Solzhenitsyn's character at home and abroad by Big Lies about his wartime record, social background, daily habits, alleged support of Russian émigré organisations, by untruthful articles about his unpublished confiscated novels, unauthorised publication of a juvenilium disowned by Solzhenitsyn, and so on. Apart from that, Medvedev also quotes numerous specific instances of Solzhenitsyn's friends and admirers who lost their membership in the Party or Writers' Union, or their jobs, for either supporting Solzhenitsyn or for opposing or traducing him when told to do so by authority.

All this is presented in Medvedev's characteristic style of dry and scrupulous precision. (Readers who recall the detailed circumstantial evidence for postal censorship in his earlier book, *The Medvedev Papers*, will recognise the style.) A whole chapter is here devoted to the account of a determined detective exercise which eventually proved that mendacious articles about Solzhenitsyn published in two obscure periodicals in Italy and Poland had in fact originated in Moscow. Medvedev throughout evinces two predominant concerns—for accuracy and for the law. This is evident from the first page: the preface explains the circumstances in which this book was published, connected with Medvedev's concern not to offend against the new restrictive Soviet laws on publication abroad by Soviet authors, consequent on the Soviet Union's signature of the International Copyright Convention. In many places in the book, he explains in detail why various official acts against Solzhenitsyn were not only oppressive but also illegal. It seems that the dread censorship itself, Glavlit, is strictly illegal. It is impressive and indeed encouraging that Soviet 'dissidents', Medvedev notable among them, and unlike so many dissidents in the West, observe their country's laws more scrupulously than their own government. When, one distant day, the laws of the Soviet Union become more liberal, one may hope that they will still be obeyed by the citizens and perhaps even by the government.

Medvedev's skills do not include evocative portraiture. Solzhenitsyn and Tvardovsky do indeed come alive in the book, but only through their own deeds and words, carefully related; Medvedev does not attempt set descriptions or indeed flights of literary criticism, though he does quote verbatim a few choice pieces of official "criticism". But then, this book is concerned with history, and he leaves literary analysis to others suitably qualified. A number of Russians who befriended Solzhenitsyn, such as the physicists Kapitsa and Pavlinchuk and the cellist Rostropovich, are briefly sketched, but again their personalities emerge through their reported deeds.

The book quotes the entire text of Solzhenitsyn's message to the Fourth Writers' Congress which he was prevented from attending. This is an eloquent attack on censorship and the personal oppression of individual writers. He points out that once a troublesome writer is dead, eventually his works find their way back to the Soviet public; Pasternak is a case in point. Solzhenitsyn quotes Pushkin with heavy irony: "They are capable of loving only the dead". He might have added the bitter words of Auden: "Let us praise while we can The Vertical man, Though we honour none But the horizontal one". But one must face the question; when we in the West praise the vertical man and condemn his oppressors, those who constantly strive by persecution, imprisonment and starvation to turn him into a horizontal one—do we help or do we hinder, do we protect or do we endanger? Understandably, Medvedev does not address himself to this question, and during a recent televised discussion when this question was tangentially debated, he maintained a dignified silence. Let us see what advice Solzhenitsyn himself has for us.

In the *New York Review of Books* of October 4, 1973, there is a transcript of a recent interview granted by Solzhenitsyn. He has this to say: "It must be understood that the East is not at all indifferent to protests from Western society. On the contrary it mortally fears them—and only them; but only when such protest is expressed by the strong and unified voices of hundreds of eminent people, by the opinion of an entire continent. Only then can an 'advanced' regime be shaken. But when protests are timid and isolated, made without faith in their success and accompanied by the inevitable reservation that 'it is also the same in Greece, Turkey and Spain', they provoke only laughter from our oppressors. . . . The West by its publicity has already done much to help and save many of our oppressed . . .". And the first of the modern dissidents, Pavel Litvinov and Larissa Daniel, in 1968 explicitly addressed their particular protest to world public opinion, adding that to address their own government and news media would be useless.

Such a message presupposes a response. And on the nature and indeed the wisdom of such a response, opinion in the West is deeply divided. Whether the victims are scientists or ballet dancers who wish to emigrate to Israel, writers who cannot publish at home, musicians who cannot perform abroad, some wish to follow Solzhenitsyn's fierce and explicit call, others prefer private pressure through private channels. Since such pressure must necessarily remain secret, the rest of us cannot form an opinion of its efficacy. Those who are in a position to exert private pressure and prefer it are right to follow this path, so long as they do not seek to warn off the grass others who see hope in a public approach. These still have to make the difficult decision whether or not to mention names, to specify the individual they are seeking to help. One must make one's own decision in each instance: perhaps fame is a form of safety, so that a notable figure will be helped by a protest emanating from a group of other notable figures (as Solzhenitsyn indicates, they need to be eminent), while an unknown victim, if named, may well suffer the more. We cannot know for sure, but when distinguished men like Solzhenitsyn, Sakharov and Levich all offer the same urgent advice, we had better heed it. Some differ: Roy Medvedev, Zhores' brother, has criticised Sakharov and Solzhenitsyn for calling for pressure from the West, and Sakharov in turn has just issued a statement regretting this, and maintaining his advice. Opinions do conflict among the victims, but this does not absolve each of us from the necessity of facing the issue and reaching a decision. Whatever their decisions, everyone with a concern for the future of Soviet society should read Zhores Medvedev's book.

ROBERT CAHN

Human chromosomes

Human Chromosomes. By E. H. R. Ford. Pp. xiii+381. (Academic: New York and London, April 1973.) £7.

DR FORD has written a book on human chromosomes which should be useful for students in the important and expanding field of medical genetics. The first third of the book includes well illustrated descriptions of mitosis and meiosis and of the practice of karyotyping. This is followed by an outline of molecular genetics and of chromosome structure leading to a discussion of dosage compensation and of the origin of chromosomal abnormalities. The last and strongest section discusses in detail the various syndromes associated with chromosomal abnormalities before describing more general matters. These include the fascinating and thought-provoking relationships between fingerprints, mental abnormality and extra chromosomes, and the problem of the relation between chromosomal abnormalities and acquired diseases like cancer.

Anybody writing a textbook in a rapidly developing field must expect to be overtaken by events, but it is particularly unfortunate that the full impact of the fluorescent and Giemsa banding techniques on the identification of human chromosomes has come after most of this book was written. These latter methods are certainly discussed but the largely redundant and inadequate earlier methods of identification are still given equal weight. More seriously many of the ambiguities of chromosome assignment which appear in the later sections could have been removed.

The outline of molecular genetics, which authors of this kind of text nowadays rightly feel they must include, serves at least one useful purpose in that it underlines the complete inadequacy of current thinking on the control of the expression of genes in explaining the necessity for dosage compensation in the X or the far-reaching effects of any particular trisomy. Neither the bacterial repressor mechanism nor even the hypotheses involving chromatin condensation in gene switching lead one to predict that an extra complete chromosome should have such disastrous effects. The problem is challenging; obviously tolerance of simple heterozygosity is essential but does this include control sequences as well as sequences specifying proteins? Tandem doubling of particular loci must also be allowed; otherwise one cannot account for the increase of genetic material on the evolutionary time scale or for the evolution of haemoglobin. In addition the new methods of identification are showing that translocations of visible portions of chromosomes are common, which suggests that the functional relations of large sections at least of chromosomes are not essential. The basic requirements of life and even the simple control of the presence of enzymes are, however, compatible with the wide karyotypic variation common in tissue culture lines. It seems inescapable that it is only the ordered development of a differentiated organism which requires a precise chromosome complement, but how are these chromosomal interactions mediated?

A book like this seems therefore to be essential reading for anybody concerned with gene expression and with the investigation of human chromosomal abnormality and genetic counselling.

P. M. B. WALKER

Variable structure

Theory and Applications of Variable Structure Systems. Edited by R. R. Mohler and A. Ruberti. Pp. x+232. (Academic: New York and London, December 1972.) $8.

"VARIABLE structure" in the title is not closely defined anywhere in the book, but has been interpreted by the different authors to include any system which cannot be described by linear differential (or difference) equations with constant coefficients. This is not an easily defensible terminology, since the structure of systems which cannot be described in this simple way is usually no less fixed than the structure of those which can. Indeed, the most interesting results presented by the authors relate to fixed aspects of structure.

Nevertheless, the motivating idea of the seminar from which the papers are taken is clear. Much work has been done on linear constant systems, and many of their structural properties are known. More general systems can have different structural properties, which may be better adapted to describing a given physical situation. The aim of the seminar was to bring together applied mathematicians interested in generating and applying results for such systems.

The outcome is an interesting collection of papers which give a view of the present state of the subject. As would be expected, most progress has been made where the problems could be most closely restricted. In particular the theory of bilinear systems has now emerged as an incomplete but already well developed area. The work of Ruberti and of Brockett on the theory of these systems is particularly noteworthy, while Mohler lists a wide range of actual or potential applications: these include economic, biological and engineering systems.

Other topics include identification, modelling, model approximation and near-optimal control. Several papers deal with biological or medical applications—models of the brain, prostheses, ecological systems—where linear constant models have limited use. The book will interest a wide range of readers, but much of its content is inaccessible without a good mathematical background.

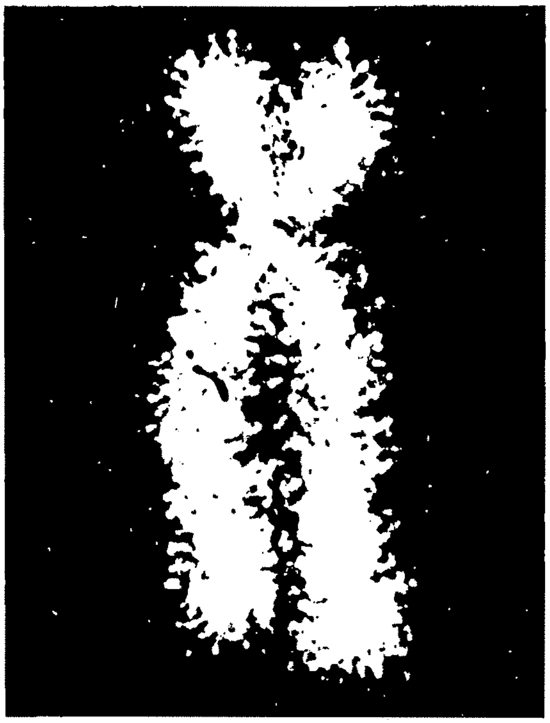
The newest in Genetics from Holt



GENETICS
by Ursula W. Goodenough and Robert Paul Levine, Harvard University
Written for a one semester course in genetics, this text covers both "classical" chromosomal genetics and "modern" molecular genetics. Each major subject is first considered as it applies to simple bacteria and viruses, and then to more complex, nucleate organisms. The beginning chapters focus on the five fundamental properties of genetic material. Succeeding chapters consider the experimental systems and procedures involved in studying gene transmission and in constructing genetic maps; functional interactions between genes and on genetic regulation, and genes in populations and the evolution of genes and species. Each chapter is abundantly illustrated with diagrams and micrographs and concludes with an extensive bibliography and problems.
January, 1974/896 pages/$14.50

PAPERS IN BIOCHEMICAL GENETICS, Second Edition
edited by Geoffrey Zubay, Columbia University and Julius Marmur, Albert Einstein College of Medicine
Providing a broad, up-to-date treatment of DNA, RNA, and protein synthesis and its regulation, these 70 papers emphasize fundamental advances in the field of biochemical genetics. The editors have provided valuable discussions of the papers, which are a worthwhile compilation for all those interested in molecular biology and biochemical genetics. The number of readings has been expanded from 48 to 70 in this edition, of which only 12 papers appeared in the first edition. The authors have cited the most recent experimental papers or reviews in the introduction to each section, so the reader can locate earlier references to classical and related publications.

Forces and Particles

An Outline of the Principles of Classical Physics

A. B. Pippard

By developing the central ideas of classical physics from an experimental rather than a mathematical point of view, this book stresses the common soil from which so many varied applications have sprung, and helps the student to see how ideas from one field can illuminate another. The treatment is taken to the point where the limitations of classical concepts become apparent, and brief accounts are given of the way in which quantum mechanics and relativity set out to enlarge the compass of physics. At every stage there are references to more specialised treatment.

£5.75

Macmillan

Bacterial Plasmids:

Conjugation, Colicinogeny and Transmissible Drug-Resistance

G. G. Meynell

The author shows how different types of plasmid were first discovered and discusses the physical structure of their chromosomes, their manner of replication and how they act to bring about conjugation and other processes they determine.

De Vitae Origine

The Origins of Life on Earth. By L. E. Orgel. Pp. 237. (Chapman and Hall: London, June 1973.) £3 boards; £1.95 paper.

Origin and Development of Living Systems. By J. Brooks and G. Shaw. Pp. xi+412. (Academic: London and New York, May 1973.) £5.

THE arrival of the space age has rocketed the interest in the study of the origin of life to new heights. The search for life beyond the Earth, the declared goal of space biology, is intimately associated with the scientifically larger question of the origin of life in the Universe. The Oparin–Haldane hypothesis of chemical evolution has now become the focus of extensive and sophisticated investigations in many laboratories around the world.

The awareness of the general public and the interest evinced by the non-specialist in science has created a demand for the latest information on the subject in what augurs to be a flood of publications on the beginnings of life. Orgel has written, not for the professional biologist or chemist, but for the freshman in college, the advanced high school student and the general reader, who has a limited knowledge of chemistry and molecular biology. Orgel himself is one of the leading practitioners in the chemistry of the origin of life. A theoretical chemist, who has turned to biochemistry and organic chemistry, he has successfully elucidated a number of chemical pathways presumed to be necessary prerequisites for the emergence of life.

From a discussion of the historical background he gives an account of the history of the Earth's primitive atmosphere and the sources of energy necessary for the synthesis of organic compounds. He then describes the processes which gave rise to the building blocks of life. Now comes the opportune moment to examine our concept of life, before embarking on a search for life beyond the Earth.

I was disappointed that a good portion of the book has been spent on the background necessary for understanding the problem. I missed the excitement and thrill which I would have expected in picking up a book on the origin of life, written by a scientist actively engaged in its study. But the clarity of presentation, and the thoroughness of the discussion on the critical issues, make this book a valuable addition to the shelves of the general reader interested in an up-to-date and succinct account of current thinking on the problem of life's beginning.

Brooks and Shaw, on the other hand, have approached their study of the origin of life from a very different point of view. Having been involved in the study of pollen grains and their relationship to microspores, they became interested in the ancient Precambrian sediments. These studies led them to the analysis of some of the oldest sediments on Earth. According to their own admission, they felt that there was a great lack of knowledge among chemists, both in the organic and inorganic fields, about the relationship of the geochemical aspect to the problem of the origin of life. Brooks and Shaw present the geochemical background to chemical evolution in readable fashion.

The book starts with an account of the Universe and the evolution of the Earth and its atmosphere. The authors then proceed to the chemicals of life, and finally to an analysis of the Precambrian fossil record and the story of carbonaceous chondrites. Although this book is designed for the non-specialist and the general reader, a great deal of the material would be of value to the investigator and advanced student.

Of major interest are the chapters dealing with the Precambrian fossil record. Here I was delighted with the note of personal involvement. The excellent pictures provide a refreshing dimension to a stimulating discussion.

The weakness of the book is that the authors, on the one hand, have attempted to cover far too much within a limited number of pages, and, on the other, aimed at too large an audience. If the book was intended for the non-specialist, some of the chapters, though well written, may be above his grasp.

CYRIL PONNAMPERUMA

Early quanta

Quantum Mechanics: New Approaches to Selected Topics. By H. J. Lipkin. Pp. xv+465. (North Holland: Amsterdam and London; American Elsevier: New York, 1973.) Dfl. 95; $33.30.

THIS book grew from the lecture notes accrued by the author while giving post-graduate courses on quantum mechanics over a decade both in the United States and in Israel. It differs considerably from many of the standard texts intended for use with such courses. It comprises six monographs on selected topics such as the Mössbauer effect, many body quantum mechanics, Kaon physics, scattering theory, Feynman diagrams and relativistic quantum mechanics. These are presented at a much earlier level than in the conventional texts alongside which they are intended to be read.

The first is based on Dirac's use of the concept of photon polarisation as a general introduction to quantum mechanics. The idea of states of polarised light leads on to the development of a matrix representation, essentially Jones's calculus. There are other texts such as *States, Waves and Photons* by Simmons and Guttmann which are both more readable and comprehensive in their coverage of this topic. Some reference by the author to Jones and Mueller matrices might be useful as reference.

The second monograph, comprising three chapters, deals with momentum transfer with specific reference to the Mössbauer effect. Here a clear and concise listing is given which includes details of earlier experiments on resonance phenomena. Momentum transfer within a solid matrix, involving phonon interactions and nuclei, is then described with emphasis on beta decay and electron scattering by complex nuclei. This monograph is mainly concerned with the concept of a form factor and requires only an understanding of a free particle and harmonic oscillator in order to be led up to a formal treatment of second quantisation.

The treatment of many particle quantum mechanics follows in the next monograph which deals in turn with fermions and the application of fermion pairs to superconductivity. The concepts of time-dependent perturbation theory are then introduced in the next monograph on the treatment of Kaon decay. A chapter on one-dimensional scattering models provides an excellent introduction to this important part of quantum mechanics and is followed by three chapters dealing with the many body interaction problem. A comprehensive presentation of Thomas-Fermi and Hartree-Foch models is followed by a treatment of elementary excitation processes including grant resonances. The final section in this monograph introduces the reader to spectral and Green's function without entering fully into their applications.

The reader is introduced next to time-dependent perturbation theory through Feynman diagrams, using third order 'bremsstrahlung' processes as an example. The polaron is also used as an example of a quantum field approach to solid state physics.

The final monograph introduces the reader to symmetries, invariance and relativistic quantum mechanics. Starting with the Dirac equation, the reader is introduced to gauge transformations, the Lorentz group as a case of symmetry transformation and finally to charge conjugation.

Each monograph in this excellent book is introduced by a summary and ends with a problem test. The book is recommended to graduate students and research physicists looking for a pedestrian but fairly informal treatment of these topics.

D. W. GOODWIN

Chromosomes decide sex

Genetics of Sex Differentiation. By Ursula Mittwoch. Pp. xi+253. (Academic (Harcourt Brace Jovanovich): New York and London, June 1973.) $16.50.

THAT sex was another example of the transmission of hereditary factors rather than an environmentally controlled duality was probably first postulated by Mendel but was still a pertinent question at the turn of the century. In the companion book, *Sex Chromosomes* (Academic, London; 1967), Ursula Mittwoch briefly reviewed the early concepts of how sex is determined, which followed the discovery of the sex chromosomes. She dealt in detail with the mechanism in plants and animals, presenting the view that sex determination may be a process not depending on specific differences of protein production.

The present book is a general and useful introduction to the subject of sex development and its control especially in vertebrates and amplifies this concept. It is important, at this stage, to distinguish between sex determination (the primary event that decides on the type of gonad that an embryo makes) and sex differentiation (the subsequent effects of the gonad on embryogenesis of the other sex structures). The aim of the book is to give substance to the idea that sex determination results from an epigenetic control that primarily resides in whole chromosomes or chromosome segments. These, because they are visibly different, are assumed to have an effect on development "which cannot be accounted for in terms of genes". In other words the suggestion is that sex chromosomes determine sex by functioning as larger units rather than through the action of individual genes: this is the first part of the hypothesis. For its second part the author turns to non-genetic DNA, its redundancy, variation and function and to the view that sex chromosomes may control sex determination by affecting differentially the rates at which cells divide and grow during embryogenesis.

The thesis that Mittwoch presents is contrasted with other hypotheses involving discrete genic determinants, as the mainspring for gonadal differentiation, and she marshals various lines of support for it. Examples are taken from the effect of heterochromatic B chromosomes on mitotic rates in plants, the effect of X chromosomes on the mitotic cycle of human cells *in vitro*, the effect of growth rates on embryonic differentiation, particularly the analysis of transdetermination of *Drosophila* imaginal disks, and finally the effect of the various environmental influences on embryonic differentiation. Indeed, the bulk of the first six of the seven chapters of the book is an introduction to the thesis developed in the final chapter.

Irrespective of whether the hypothesis which this book discusses will ultimately turn out to be right or wrong, it is important that attention has been drawn to it. Experiments of nature should be scrutinised and experiments should be devised to see if they falsify the idea, but until then it should rank with the discrete gene hypotheses of sex determination.

PAUL E. POLANI

Insects of Europe

A Field Guide to the Insects of Britain and Northern Europe. By Michael Chinery. Pp. 352. 60 plates. (Collins: London, November 1973.) £2.95.

THIS latest addition to the Collins' Field Guide series follows their recent pattern of including Europe, in this case Europe north of the Alps. But anyone expecting to identify any insect encountered, either in this country or while holidaying on the Continent, will be sadly disappointed. This field guide only claims to enable people with no previous knowledge of the subject to first make sure that what they have found is an insect, and second to place it in the correct order and either the appropriate superfamily or family. For further identification to species a fairly extensive bibliography is provided, although some may be recognised from the superb colour plates. Those depicting lepidopterous larvae are, however, rather garish and are irritatingly interleaved with the glossary.

The glossary surprisingly omits the only obvious competitor, *The Oxford Book of Insects*. Although this new guide does not contain the comprehensive coverage of butterflies and dragonflies, it has advantages over the other in containing simplified keys, well illustrated with thumbnail sketches. The author admits that these ignore the 'odd-man-out' but they are nonetheless very valuable.

There is an excellent general introduction to entomology containing essential details of anatomy and biology, with notes on collecting and preserving insects. Unfortunately the Code for Insect Collecting is printed on the dust jacket which may become separated from the book. There is a concise chapter on classification and taxonomy and a list of entomological suppliers. It is unfortunate that the Lepidoptera section of the revised Kloet and Hincks could not be used, but the use of archaic Psocoptera nomenclature is less forgivable. Little content would have been lost by covering only British insects, although I believe there is a similar need for such a guide on the Continent. The book will sell on first impressions alone, and is extremely good value.

R. COLIN WELCH

Theory of athletics

The Mechanics of Athletics. By G. Dyson. Pp. 240. (University of London: London, September 1973.) Boards £3.30; paper £2.20.

THIS book, by the Director of Physical Education at Winchester, formerly Chief National Coach to the Amateur Athletic Association, is one that every athlete wishing to add to his skill should continually study. Mr Dyson has vast experience of athletics and coaching, and makes clear at the outset his creed that the theoretical understanding of what one is supposed to be doing is the key to improvement. "Those enamoured of practice without science [theory] are like a pilot without rudder or compass, never certain where he is going", he quotes (from Leonardo da Vinci). But he well understands that the theory must be allowed to sink in and become so much part and parcel of the method of the performer that he comes to do the right things automatically, and it is the task of a coach to induct such theory with skilful application. This of course holds for most if not all instruction: the existing level of a pupil's state of understanding and attainment must be assessed and the philosophic pill gilded accordingly.

After first lucidly expounding what is needed to be known for his purposes about motion and force, and about rotatory motion with its less obvious centripetal and gyroscopic consequences, Mr Dyson takes his readers through everything that he has found to be essential in comprehending the correct principles of running, hurdling, jumping (high and long), pole vaulting, shot putting, and throwing the hammer, discus, and javelin. No great prior knowledge of mechanics is required from the reader. Any athlete who has come to a steady state of achievement, yet nevertheless feels he ought to be able to do better, may well find the secret to his making fresh progress in the relevant chapters of this book. It has seen five previous editions, been translated into several languages including Japanese (who mean business in the sporting world, be it noted), and not surprisingly is required reading in many universities.

It is hard to know how many readers of *Nature* may also be interested in athletics, but if they are not themselves, their children or friends may be, and whether or not these have access to coaching at high level, this book could well make an admirable scientific gift of permanent value that would do much to add to their enjoyment of athletics both through greater appreciation of the fundamentals and improvement of their own performance.

R. A. LYTTLETON

matters arising

30 S DNA: intermediate or artefact?

Sir,—Goldstein and Rutman[1] have pulse-labelled the DNA of Ehrlich ascites cells growing intraperitoneally in a mouse with either ^3H or ^{14}C-thymidine. The DNA was subsequently extracted from the cells and its molecular weight measured on gradients of alkaline sucrose.

After short pulse times (<2 min), the labelled DNA had a sedimentation coefficient of 9S indicating the presence of short intermediates in DNA replication ("Okazaki" fragments[2]). After longer times (10–30 min) they observed labelled DNA which sedimented somewhat more slowly than the bulk DNA (30S as opposed to 44S) and they claimed that this represented a discrete intermediate in the replication of DNA. This interpretation is improbable.

If a long molecule is labelled at one end (as happens with a short pulse label) and then sheared, the labelled molecules will always appear to have lower molecular weights than the bulk material. This artefact is a result of the different labelling patterns of pieces that derive from molecules labelled only at the ends, as compared with molecules labelled throughout their lengths. This effect has been described qualitatively in ref. 3 and a complete mathematical analysis can be found in ref. 4.

The observation of apparently slightly smaller lengths of pulse-labelled DNA (for example, 30S as opposed to 44S) is therefore not in itself evidence for a special class of DNA molecules. It merely demonstrates that the label goes on to the ends of growing DNA strands. This criticism does not apply to the observation of 9S DNA. The most plausible interpretation of the data is that there is an intermediate in DNA replication of about 0.4×10^6 daltons and that this is linked directly on to the end of the growing DNA molecule.

Falmer, Brighton BN1 9QG

Drs Goldstein and Rutman respond: The points from our study[1] of 'self-chase' Ehrlich ascites tumours which supported the DNA replication model involving sequential tandem ligations of 9S→30S and 30S→44S were: (1) maximal radioactive pulse-labelling of new 9S DNA by 2 min; (2) sharp peak transitions in alkaline sucrose gradients of labelled DNAs from alkaline-lysed cells, with no broad envelope of DNA sizes observed (2–120 min); (3) time of appearance of bulk-size labelled 44S DNA, 20–30 min, was best explained by ligation of 20 of the 9S chains to form 30S DNA and further ligation of 3 of 30S to form 44S; if 9S were directly linked to the end of a growing, long molcecule, as proposed by Lehmann and Ormerod[3,4], it should have taken 120 min to form 44S with an initial polymerisation rate of 600 deoxynucleotides per min; (4) at that rate of synthesis, excess DNA per cell would have been made in a 10 h S phase[1].

If ligation processes are under the control of replication fork(s)[1], before any ligation could begin, RNA primer molecules, to which Ehrlich cell Okazaki fragments are probably covalently linked[5,6], would have to be removed and replaced by DNA, as described for *E. coli*[7]. These latter mechanistic requirements with respect to 9S DNA taken in conjunction with our approximate kinetic analyses of 44S formation indicate that, like 9S, 30S DNA is a discrete replicative intermediate and not an artefact. The crux of this discussion rests on our choice between alternative interpretations of the data.

We have subsequently shown that bifunctional nitrogen mustard interferes with both synthesis of 9S DNA chains and their eventual step-wise conversion to 44S through 30S DNA[8].

Impact erosion by jets of dilute polymer solutions

Sir—Results described in the letter by Kudin *et al.*[1] increase the number of types of materials which have been cut by an impacting jet containing traces of soluble polymers. The hypothesis propounded by the authors, that increase in erosion capability is due to the rigidity of large aggregates of the polymer when subjected to high loading rates is not, however, correct.

In work carried out at the Universities of Leeds and Missouri-Rolla[2,3] work on polymer addition has shown an improvement over plain water jets in impact erosion of rock (Fig. 1). The fluid was filtered at 10 μm before entering the pumping system. This would hold back any large aggregates which Kudin *et al.*, suggested act as solid particles at short time scales and cause the

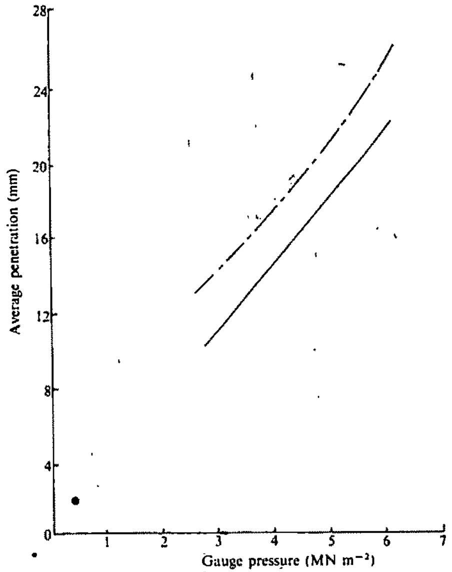

Fig. 1 Comparison between penetration of a water jet and jet containing Polyox into sandstone under varying pressure (after ref. 2). ——, Ordinary jet; – – –, with 0.1% Polyox.

erosion. The likely cause of the improvement is the increased cohesion of the jet stream, rather than any change in physical property of the fluid—such changes in density and viscosity are negligibly small in the concentrations used —or solid particle behaviour of polymer and associated solvent. That this is so is shown by the increasing effect of the polymer on jet cutting ability as the target is moved away from the nozzle (Fig. 2). Photographic evidence of the improvement in cohesion is available[4] for studies where the surrounding fluid is air and this improvement may be enhanced when the jets are submerged as apparently was the case in ref. 1. The presence of the central core on the surface of the target during the erosion process (Fig. 2c of ref. 1) is a further indication that the impacting fluid, rather than a series of solid impacts as suggested[1] is the cutting agent since such a cone is a feature of water jet erosion[5].

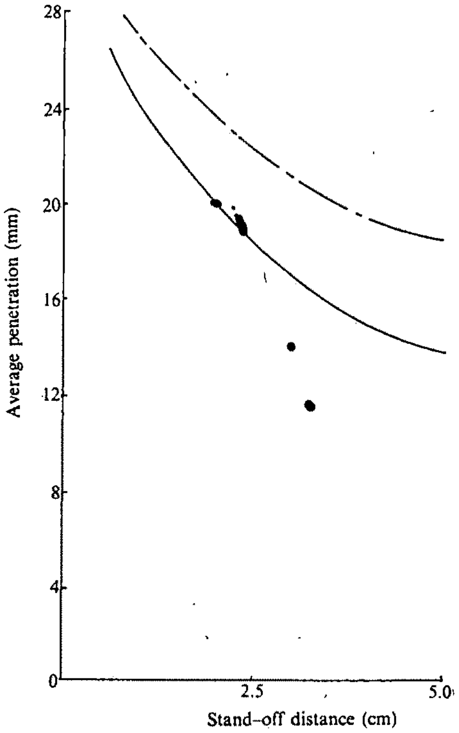

FIG. 2 Comparison between penetration of a water jet and a jet containing Polyox into sandstone with increase in target distance (after ref. 2). ——, Ordinary jet; — — —, with 0.1% Polyox.

The individual and the information problem

THE skewness of the distribution of journals in which individual scientists and research institutes as a whole publish their findings, shown by Blaxter and Blaxter[1] in their recent paper, will come as no surprise to most research librarians. A similar phenomenon of the distribution of journals relevant to particular specialities has been known for a number of years.

As long ago as 1927, Gross and Gross[2], studying chemical literature, developed a theory of evaluating periodicals based primarily on the assumption that the value of a periodical to a scientific worker is in direct proportion to the number of times it is cited in the scientific literature. The results obtained showed this typical distribution, with a relatively small number of periodicals containing a high percentage of the papers thought to be relevant to the subject, but with the subject's total literature widely dispersed through many journals. A similar conclusion was arrived at by Bradford[3] and later by others working on Bradford's Law[4,5]. Over the past 25 yr the literatures of many different subject fields have been analysed, and all show similar distributions[6-10]. Garfield[11] has recently shown this same skew distribution to be a property of the scientific literature as a whole, important work being concentrated in relatively few journals.

Blaxter and Blaxter's estimations for the optimum size of a working library satisfying 90% of the needs of 90% of its users could probably be reduced even more, as it is very likely that several of the twenty-five journals relevant to each of the five subject fields would be the same. The 25 yr estimated working life of the library stock only holds true if the current research interests of the workers do not change appreciably during this time. When major new fields are entered new journals are needed. Similarly, journals supporting superceded research work should be pruned from the library stock long before they are 25 yr old.

All librarians are very well aware of the costs of subscribing to, and maintaining long back-files of journals, and much bibliometric work has been carried out in an attempt to minimise these costs. This indication that users appreciate these points too makes a welcome alternative to their more usual requests for yet more new journals.

APPOINTMENTS VACANT

UNIVERSITY OF BRADFORD

POSTGRADUATE SCHOOL OF STUDIES IN MATERIALS SCIENCE

Applications are invited for an SRC Research Assistantship in the School of Materials Science, tenable for 2 years in the first instance. The research is into the relationship between the structure and catalytic properties of some transition metal oxides. High resolution transmission electron microscopy will be the main instrument used to characterise structural changes due to catalytic activity. Facilities for this study are available within the group. Applicants should have completed a PhD degree or have had equivalent research experience. Some preference will be given to candidates with a knowledge of electron microscopy or of the surface and structural chemistry of oxides. Initial salary within range £1,482 to £1,929 p.a. Superannuable.

Enquiries for further particulars and applications should be sent as soon as possible to Professor D. Bijl, Post MS/RA/SRC/X, Postgraduate School of Studies in Materials Science, University of Bradford, Yorkshire BD7 1DP. (314)

The University of Leeds

DEPARTMENT OF CHEMICAL PATHOLOGY

DIVISION OF STEROID ENDOCRINOLOGY

Applications are invited for a post of post-doctoral RESEARCH FELLOW. Candidates should preferably have some experience of gas chromatography of steroids. The work will be carried out in collaboration with the MRC Clinical Research Centre at Northwick Park, London, and is supported by the Medical Research Council.

The appointment will be made for one year in the first instance, with possible renewal for a further two years. Salary on the scale £1,929-£2,388.

Applications should be submitted as soon as possible to Professor S. R. Stitch, Division of Steroid Endocrinology, Department of Chemical Pathology, University of Leeds, LS2 9JT, to whom informal enquiries may also be made.

(319)

THE DYSON PERRINS LABORATORY OXFORD UNIVERSITY

Applications are invited from organic chemists for the position of postdoctoral research assistant to work with Dr G. T. Young on the synthesis of peptides of pharmacological interest. Experience in the field is desirable but not essential. The appointment will be for 1 year, renewable for a second year, commencing not later than September 1974; applications will be accepted from those expecting to complete doctoral work next summer. Salary in the range £1,821-£1,929-£2,058 p.a.

Applications, including curriculum vitae, should reach Dr G. T. Young, The Dyson Perrins Laboratory, South Parks Road, Oxford OXL 3QY, as soon as possible and not later than March 15. (303)

HARWELL

Theoretical Physics at Harwell

The Theoretical Physics Division has a varied programme of research which includes both applied research such as heat transfer, reactor materials and reactor safety, as well as longer term scientific research in nuclear theory, atomic and molecular theory, solid and liquid state theory in the broad areas relevant to present and future activities of Harwell and of the nuclear industry. To add to the strength of our existing teams we are seeking applied mathematicians and theoretical physicists of proven research ability with interest and experience in the following fields:

Hydrodynamic Theory and Physics of Fluids

Atomic Theory

Molecular Theory

Solid State Theory

Computer Modelling of Reactor Materials

Applicants should have a good honours degree and relevant postgraduate experience. However, more important than the particular expertise so far acquired are the characteristics of theoretical and mathematical ability, originality and versatility and the willingness to work on applied problems as well as to contribute to Harwell's longer term scientific programmes. Appointments will be either to the permanent staff or to Fellowships with a salary or stipend in the range £2,000 - £3,500 p.a. depending upon experience and ability.

For further details and application forms please write to Appointments Section 'A , A.E.R.E., Harwell, Didcot, Berks.

(256)

NATIONAL INSTITUTE FOR BIOLOGICAL STANDARDS AND CONTROL

HAMPSTEAD, LONDON

JUNIOR TECHNICAL OFFICER/TECHNICIAN required in the Antibiotics Division to work in a laboratory concerned with the evaluation and control of antibiotics used in therapy. Candidates should possess a degree/HNC or equivalent in one of the biological sciences.

Graduates will be appointed to the Junior Technical Officer scale between £1,533-£2,199 Holders of HNC or the equivalent will be appointed to the Technician grade £1,566-£2,418 p.a. Experience in antibiotic assay by microbiological and chemical procedures is desirable.

Please apply with details of age, qualifications and experience, to Mr P. A. Collingridge, National Institute for Medical Research, The Ridgeway, Mill Hill NW7 1AA. Tel. 01-959 3666. (245)

UNIVERSITY OF STIRLING

LECTURESHIP IN BIOCHEMISTRY

Applications are invited for the post of Lecturer in Biochemistry. Applicants should have teaching experience and research interests preferably in the field of enzymology, developmental biochemistry, or biochemical adaptation to specialised environmental conditions.

Further particulars are available from the Secretary (NAT), University of Stirling, Stirling FK9 4LA, to whom applications, together with the names of two referees, should be sent by February 8, 1974. (248)

TECHNICIAN/RESEARCH ASSISTANT

required for Paediatric Unit to join research group working on aspects of mineral metabolism. AIMLT or equivalent required. Salary according to experience and qualifications within appropriate scale.

Further details from Dr D. Barltrop, Tel. (01) 723 1252 Ext 110. Apply, The Secretary, St Mary's Hospital Medical School, Paddington W2 1PG. (294)

Senior Research Microbiologist

Extension of our activities has created the need to appoint a MICROBIOLOGIST to head up a new unit in our well equipped microbiological laboratories situated in Nottingham.

The unit will carry out research into rapid methods for the detection of micro-organisms, particularly those of importance as potential contaminants of our broad range of pharmaceutical, cosmetic and food products. He will plan, develop and control the necessary programme of work.

Applications are invited from holders of a research degree aged between 30-35 with proven experience in a Research Institute or a research-orientated industrial concern. Additionally the personal qualities of drive and creativity are necessary together with high level communication skills since collaboration with scientists from other disciplines is an integral part of the job.

Conditions of employment are first class and include profit sharing and contributory pension schemes. Some help with relocation will be given if appropriate. Prospects of career development within the Group's scientific departments are very good.

Please write, quoting ref. U.176, to: **J. F. Pattison, Employment Manager,**

The Boots Company Ltd.,
Station Street, Nottingham.

(255)

Wellcome

Biochemist

There is a vacancy in the Department of Biological Chemistry for a Biochemist to take part in a programme of work on chalones. Some knowledge of modern biochemical separation techniques is required and an interest in the process of cell division would be an advantage. The candidate should be prepared to undertake research of a fundamental kind and will be involved in collaboration with a university department.

The appointment carries excellent conditions of employment in modern, well-equipped laboratories located in pleasant parkland surroundings convenient for Beckenham, Bromley and Croydon.

Applications, giving brief details of background and experience, should be sent, quoting reference U.435, to:

The Personnel Manager,
Wellcome Research Laboratories,
Langley Court,
Beckenham,
Kent BR3 3BS

1971

(353)

ANGLO-EUROPEAN COLLEGE OF CHIROPRACTIC

Department of Pre-Clinical Studies

1. SENIOR LECTURER OR LECTURER (Grade II) in ANATOMY OR COMPARATIVE ANATOMY
2. SENIOR LECTURER OR LECTURER (Grade II) in MICROBIOLOGY AND/OR PATHOLOGY

Applications are invited for the above full-time posts to commence as soon as possible. Candidates must have suitable academic and/or professional qualifications and some teaching experience.

Initial salary dependent upon good qualifications and experience within the Burnham Scale ranges: £3,291-£3,655 for Senior Lecturer, £2,515-£3,243 for Lecturer Grade II. The posts are pensionable under the college's own scheme.

Detailed applications, including a curriculum vitae and naming two referees, should be sent to:

The Dean,
Anglo-European College of Chiropractic,
2 Cavendish Road,
Bournemouth,
Hampshire BH1 1RA.

(262)

UNIVERSITY
OF DUBLIN
Trinity College

JUNIOR LECTURER IN APPLIED MATHEMATICS

Applications are invited for the above post. Candidates should have a research interest in one of the following areas: Applied Mathematics, Theoretical Physics, Mathematical Biology or Numerical Analysis.

Salary scale: £1,969 by £126 to £2,473.

Marriage and children's allowances are paid and there is a non-contributory F.S.S.U.-type Pension Scheme.

Further particulars and application forms may be obtained from:

The Staff Secretary,
West Theatre,
Trinity College,
Dublin 2,

who will receive completed applications up to February 18, 1974.

(177)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

CHAIR OF PHARMACOLOGY

The University of Nottingham invites applications from registered medical practitioners for a new Chair of Pharmacology which has been established initially within the Department of Physiology in the Medical School. The salary will be within the appropriate Professorial range with membership of F.S.S.U.

The Department of Physiology was established in the new Medical School in 1968 and is currently housed in recently built accommodation. Very good physical facilities will be available for the Professor of Pharmacology and his supporting staff in the new Medical Sciences Building which is approaching completion. The first medical students entered the University in October 1970 and clinical training began in 1973. It is hoped that the Professor of Pharmacology will be able to take up his appointment as soon as possible.

Full particulars of the appointment, together with copies of relevant documents concerning the Medical School and application forms, may be obtained from the Senior Assistant Registrar, Medical School, University Park, Nottingham NG7 2RD. Applications should be returned by March 1, 1974. (286)

UNIVERSITY OF OXFORD

DYSON PERRINS (ORGANIC CHEMISTRY) LABORATORY

DEPARTMENTAL ASSISTANT

Qualification: Organic chemist of postdoctoral status. Appointment: 2 years, extension to 3 possible. Duties: Collaboration with one of the research groups and in the design and supervision of undergraduate experiments. Salary: from £1,929 p.a. plus FSSU.

Starting date: October 1, 1974. Applications with 2 referees' names to Administrator, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, as soon as possible before February 25. (304)

AUSTRALIAN NATIONAL UNIVERSITY

THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

FELLOWSHIP IN MICROBIOLOGY

Applications are invited for a position of Fellow, tenable in the Department of Microbiology (Head of Department, Professor G. L. Ada).

Groups in the Department work in the fields of animal virology and cellular immunology. It is preferred that applicants should have had postdoctoral experience in the field of antigen structure and modification.

The salary range for a Fellow is $A10,432 to $A14,288 per annum and the appointment is for an initial period of five years; thereafter, he may be reappointed until retiring age. A Fellow is entitled to one year's study leave on full salary, plus a contribution towards travel and other expenses, in every seven years of service.

Superannuation is on the F.S.S.U. pattern with supplementary benefits. Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra.

Enquiries on academic aspects of the position should be addressed to Professor G. L. Ada in the University. Information about the method of application should be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.
